Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
+ *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter `http://books.google.com` durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

Warrington, Dr. W. B. (O.P.), 258
Weber, Dr. F. P. (O.P.), 94, 261
West, J. (L.), 188, 300
Williams, Dr. Leonard (O.R.), 347, 690
Wright, Sir Almroth E. (O.P.), 424
Wylie, Dr. Andrew (O.P.), 524

CLINICAL LECTURES.

Bronchitis. Fœtid. Dr. H. Rabe, 284
Cancer of the rectum. Inoperable. Dr. W. Alexander, 394
Cancer of the Uterus. Dr. C. Lockyer, 172
Deafness. Different varieties of chronic. Prof. Aristide Malherbe, 654
Death. Sudden. Prof. R. Saundby, 312
Diet in relation to practice. Modern theories. Dr. R. Hutchison, 114
Diet of the aged. Dr. Harry Campbell, 6.
Embolism consequent upon lesions of the left heart. Prof. Paul Claisse, 88
Epiphysitis. Chronic infective. Edred M. Corner, 368
Indigestion in children. Dr. G. F. Still, 256

INDEX.

Kidney. Early diagnosis in surgical diseases of the. Dr. David Newman, 496, 522
Laboratory methods in the diagnosis of typhoid fever. Prof. Léon Blum, 340
Laryngitis. Tubercular. Dr. Andrew Wylie, 62
Marasmus. Infantile. Dr. G. F. Still, 604
Obstetrical practice. Ordinary. How to set to work in. Prof. R. de Bovis, 578
Pannus following trachoma. Treatment of by gonorrhœal pus. Vilmos Goldzieher, 228
Phlebitis. The medical treatment of. Prof. Albert Robin, 470
Psoriasis. Dr. Arthur Whitfield, 34
Rheumatism. Chronic. Clinical varieties of. Dr. J. Teissier, 422
Sciatica. Dr. Robert A. Fleming, 682
Shoulder. Injuries about. Diagnosis of. J. Dundon, 200
Squint. Internal. Dr. Patrick Maxwell, 446
Surgical technique. General. Dr. de C. Wheeler, 144
Tuberculosis. Some landmarks in. Prof. W. St. Clair Symmers, 630
Uterine displacements. Surgical treatment of. Dr. Arthur E. Giles, 548

CLINICAL RECORDS.

Aneurysm of the descending aorta, 609
Cornual gestation, 583
Emphysema, 42
Erb's paralysis from traumatism, 529
Labour shock, 292
Lupus and Calmette's tuberculin method, 206
Optic neuritis in cerebral tumours, 153
Phthisis. Chronic. Calmette's test, 375
Pregnancy complicated with fibromyoma, 346
Renal calculus in a child, 639
Surgical cases, 659

CORRESPONDENCE— FOREIGN.

FRANCE—

Abortion. Criminal, 481
Adenitis. Tuberculosis of neck, 295
Aix-les-Bains, 666
Amenorrhœa of lactation, 212
Aortic aneurysm, 433
Appendicitis. Chronic. In children, 664, 694
Bee stings, 265
Broncho-pneumonia, 642
Cancer, Prognosis of, 324
Cancer of the stomach, 240
Cirrhosis of the liver. Atrophic, 481
Coryza. Acute, 19
Coxalgia, 73, 353
Cystitis. Tuberculous, 213
Diphtheria. Local treatment of, 265
Drink diet in cardio-renal affections, 506
Eclampsia. Treatment of, 561
Epithelioma. Cutaneous, 184
Erythema of infants, 406
Fœtid bronchitis, 296
Goitre, Exophthalmic, 481
Gold in therapeutics, 325
Gonorrhœa. Prophylaxis of, 19
Gray oil. Injections of, 589
Hæmophilia, 157
Hæmoptysis, 406
Hyperhydrosis of the feet, 664
Ichthyosis, 380
Intestinal antisepsy in children, 506
Medullary anæsthesia, 506
Milk diet, 562
Mistletoe as a hypotensor, 616
Nævi. Pigmentary, 481
Nucleinate of soda, 379
Obesity. Treatment of, 406
Ophthalmia. Purulent. treatment of, 406
Ophthalmo-diagnosis of consumption, 127
Ophthalmo-reaction, 185
Orchitis, 506
Paratoxine, 100
Pleurisy. Cardiac, 379
Polyarthritis deformans, 589
Polyuria. Treatment of, 158
Pruritus of the anus, 19
Pulmonary consumption, 46, 72
Retinitis. Diabetic, 642
Serum therapy, 100
Sticking plaster, 664
Stitch, 617
Sycosis of the beard, 296
Thiosinamine and deafness, 380
Thiosinamine and fibrolysine, 694
Tonsils. Hypertrophy of, 433
Vascular nævi. Treatment of, 184
Vegetations of the genital organs, 433
Vomiting. Treatment of, 213
Warm baths for pneumonia, 185

GERMANY—

Anæmia. Pernicious, 643
Arteritis and rheumatism. Septic, 325
Atrophy. Progressive muscular, 590
Blindworm tubercle bacilli, 240
Brain. Prolapse of, 457
Calculus. Bronchial, 665
Cerebral tumour, 457
Chills as a cause of disease, 506
Cirrhosis of the liver. Lymphatic, 665
Diabetes conjugalis, 158
Diabetes. Renal, 563, 590
Echinococcus, 665
Epilepsy after injury, 457
Epityphlitis. Ætiology and pathogenesis of, 482
Gastric juice. Excessive flow of, 457
Hemisystole, 100
Hydronephrosis. Intermittent. With abnormally placed supernumerary renal artery, 507
Hyperæmia. Treatment of, 381
Hypnotics. Chemical, 296
Infants. A Society for the Care of, 20
Infants. Artificial feeding of, 47
Keating-Hart fulguration treatment of cancer, 643
Laminectomy, 457
Larynx. Disease of, 74
Lung, Resection of for bronchiectic cavities, 325
Medical men and notice board, 19
Medicine and over-culture, 433
Meningitis with formation of gas, 457
Middle-ear inflammation, 534
Œsophageal bodies with gangrene of the lung, 380
Ophthalmo-reaction, 185, 265
Pancreatic disease. Demonstration of, 665
Papilloma of the bladder. Recurrences of, 213; discussion on, 241
Peritonitis after gunshot wound, 617
Phlegmons of sheaths of tendons. Treatment of, 407
Poisoning. Two cases of, 563
Pregnancy and tuberculosis of the larynx, 534
Proctitis sphincterica, 665
Prostate. Carcinoma of, 73
Prussia. Mortality of, 534
Pulmonary metastases in epithelioma of the chorion, 434
Rontgen illumination, 213
Stomach. Surgery of, 457
Syphilis. Serum diagnosis of, 354
Syphilis. Treatment of by arsenic, 128
Talus. Removal of, 241
Thyroid. Technique of transplantation, 643
Trypsine and amylopsine, 407
Tuberculin in tuberculosis of the kidney, 127
Tuberculin reaction, 265
Tuberculosis. Ileo-cæcal, 20
Tuberculosis of the supra-orbital margin, 127
Tuberculosis. Pulmonary. And gravidity, 380
Tumours. Malignant, 20
Tumour of the brain of a dog, artificially produced, 241
Tuberculosis. Reduced mortality from, 617
Typhlitis. Differential diagnosis of, 407
Volvulus of the ascending colon, 407
Wassermann's serum in syphilis, 186

AUSTRIA—

Acne necrotica, 214
Acromegalia, 434
Altered secretion and extirpation, 266
Ankylosis and contractions, 326
Arsenic and autolysis, 74
Arteria pulmonalis. Injury to, 48
Arthritis deformans. Polyarticular, 381
Atresia of œsophagus, 128
"Beckenflecken," 266
Blood letting in necrosis, 408
Calmette reaction. The, 297
Cane sugar in urine, 355
Carcinoma. Gastric, 297
Carcinoma. Squamous epithelial, 434
Cerebro-spinalis epidermica, 214
Chlorate of potassium poisoning, 355
Chorea and melanosis, 128
Chorea. Senile, 618
Club-foot therapy, 48
Cramps and convulsions, 21, 101
Cutaneous absorption, 407
Cysticerci in the brain, 591
Diarrhœa. Adipose, 297
Diphtheritic liver and spleen, 355
Empyema of frontal sinus, 266
Epidermolysis bullosa hereditaria, 355
Epiploitis, 241
Erythrodermia, 186
Eunuchs, 695
Exudation. Vagrant pleuritic, 74
Fatigue. Toxine of, 618
Female milk with rennet and acids, 159
Fibrolysin, 381
Fistula gastrocolica, 20
Gangrene. Cutaneous, in herpes zoster, 534
Genital malformation, 326
Head. Bony defect in, 643
Hepatic rupture, 48
Hydronephrosis, 694
Intestines. Rupture of, 214
Iodglidine, 159
Laryngo-rhinology, 483
Leucocythæmia. Lymphatic and chylothorax, 241
Lympho-sarcoma, 186
Mammæ and genitals. Relation of, 297
Metastasis, 297
Milk analysis. Microscopic, 266
Mongol habitus, 326
Myæsthenia, 591
Myxœdema, 326
Narcosis of the Arabians, 618
Nasal septum. Perforation of, 326
Nephrectomy and tubercle, 695
Nephritic tuberculosis, 534
Œsophagus. Pulsating diverticula of, 186
Œsophagus. Spasms and dilatation of, 507
Orthostatic albuminuria, 128, 507, 535, 563
Perennial horns of the deer, 434
Pessaries. Intra-uterine, 507
Phymosis, 408
Poisons. Antagonism of, 482

OPERATING THEATRES.

French Hospital—
  Kronlein's operation, 503
Great Northern Hospital—
  Double inguinal hernia. Single incision, 348
  Impacted stone in ureter, 660
  Pyonephrosis with displaced heart, 154
  Tuberculous disease of the os calcis, 401
Guy's Hospital—
  Fracture of femur, 610
  Fracture of radius and ulna, 207
  Laparotomy for cancerous growth, 610
  Rectum. Excision of, 207
King's College Hospital—
  Acute appendicitis, 593
  Mastoid disease, 42, 476
  Separated lower epiplysis of femur, 376
Paddington Green Children's Hospital—
  Imperforate rectum. Operation for, 235
  Sinus thrombosis secondary to mastoid abscess, 95
Royal Free Hospital—
  Cholecystostomy, 320
  Fæcal fistula, 13
  Fractured patella, 181
  Fracture of skull, 477
  Hydatid of the liver, 454
  Inguinal hernia in adults, 557
  Retro-pharyngeal abscess, 261
  Tuberculous disease of the wrist, 70
Royal Southern Hospital, Liverpool—
  Palmar aneurysm, 96
St. Thomas's Hospital—
  Acute appendicitis, 645, 691
  Carcinoma of the breast, 292
  Elbow. Ankylosis of, 531
  Gall-bladder. Enlarged, 123
Victoria Hospital for Children.
  Inguinal hernia, 430

MODERN THERAPY.

MEDICAMENTA VERA P. D. & Co.

Body Nutrition.

EGG EMULSION OF COD LIVER OIL.
(Emulsio Olei Morrhuæ cum Vitellis, P., D. & Co.)

Contains 40 per cent. of the best Lofoten Cod Liver Oil, emulsified with fresh eggs and flavoured with brandy.

Therapy.

A nutrient and reconstructive of exceptional value, rich in the essentials of vital heat and force, and possessing a gentle stimulant power which is valuable in many cases of debility. It is entirely free from rancidity, and well masks the slight flavour inseparable from even the best cod liver oil.

EGMOL.
(Emulsio Olei Olivæ cum Vitellis, P., D. & Co.)

Contains 40 per cent. of virgin olive oil, emulsified with fresh eggs and flavoured with brandy.

Therapy.

Acceptable to those who cannot tolerate cod liver oil. *The Lancet* states (Nov. 2, 1907, p. 1329) :—"It is clearly a powerful nutritive agent. There is no reason why olive oil should not favour assimilation and nutrition as well as does cod liver oil."

COD LIVER OIL EMULSION, 40%—
with hypophosphites of calcium and sodium.
(Emulsio Olei Morrhuæ, 40% P., D. & Co.)

COD LIVER OIL EMULSION, 25%—
with hypophosphites of calcium and sodium.
(Emulsio Olei Morrhuæ, 25%, P., D. & Co.)

Therapy.

Two agreeable preparations of specially pure ingredients so presented as to be least likely to disturb digestion, and combining the tonic alterative properties of the hypophosphites with the nutritive value of the oil. The alternative proportions of the latter enable the physician to suit the dose to the requirements of his patient.

CREOSOTED EMULSION OF COD LIVER OIL with hypophosphites of calcium and sodium. (Emulsio Olei Morrhuæ c. Creosoto, P., D. & Co.)
Represents 25 per cent. of finest cod liver oil and 1 per cent. of pure beechwood creosote.

Therapy.

The germicidal and tonic properties of creosote render this preparation highly beneficial in bronchial and pulmonary affections. It eases cough, disinfects mucus, facilitates expectoration and increases nutrition.

These emulsions are supplied in bottles of 8 and 16 fluid ounces.

Please specify "P., D. & Co." when prescribing or ordering.

PARKE, DAVIS & CO., 50-4 BEAK ST., REGENT ST., LONDON, W.

128

The published statements of prominent surgeons of all countries show that

ARGYROL

(Silver Vitellin)

is the best silver salt, and that no known agent can compare with it in eradicating gonococcal and other infections, speedily and without discomfort to the patient.

Argyrol is used in 10 per cent. solution as injection in gonorrhœa every 3 hours; in 25 per cent. solution as instillation (diseases of eye) every half hour or hour, and in 25 per cent. solution as local application (throat, vagina, etc.) once daily.

Produced by

BARNES & HILLE,

32 Snow Hill, LONDON, E.C.

One unique effect of

OVOFERRIN

(Iron Vitellin)

is its property of improving the patient's general nutrition in a very striking manner.

Literature on Ovoferrin by recognized authorities in medicine in America and Europe, show that it is a hæmatinic and general tonic of very unusual value.

Ovoferrin is furnished by chemists, on prescription, in twelve-ounce bottles. The dosage is one tablespoonful in wine-glass of water or milk three times daily.

Produced by

BARNES & HILLE,

32 Snow Hill, LONDON, E.C.

Bronchitis, Winter Cough.

At this time of the year every medical man has under his care cases of "winter cough," especially of elderly people, that do not readily yield to treatment. We have a vast amount of evidence of the most positive character, showing the efficacy of Angier's Emulsion in relieving these very troublesome coughs. By its peculiar soothing, lubricating properties, it relieves the cough, facilitates expectoration and allays inflammation. Moreover, Angier's Emulsion rapidly improves nutrition and effectually overcomes the constitutional debility so frequently associated with these chronic cases. One very forcible reason for prescribing Angier's Emulsion, is that patients are always pleased with it, and frequently comment upon its soothing, "comforting" effects. The routine use of Angier's Emulsion for chronic bronchitis and "winter cough" has the endorsement of all medical men who have had opportunity of closely observing its effects.

FREE SAMPLES TO THE MEDICAL PROFESSION.

ANGIER'S EMULSION

(Petroleum with Hypophosphites).

THE ANGIER CHEMICAL CO., Ltd., 32 Snow Hill, LONDON, E.C.

PHYTIN

IS THE NATURAL SALT OF PHOSPHORUS, PRESENT IN SEEDS AND VEGETABLE TISSUES. NO OTHER DRUG CONTAINS SO LARGE A PERCENTAGE (22.8) of

ASSIMILABLE PHOSPHORUS.

Supplied in form of CAPSULES (each containing the Dose—4.2 grains), or in POWDER, or in LIQUID (for Club & Hospital Practice).

Society of Chemical Industry in Basle (Pharm. Dept.), 8 Harp Lane, London, E.C.

K. & O. DOUCHE FOR THE APPLICATION OF GLYCO-THYMOLINE TO THE NASAL CAVITIES

GLYCO-THYMOLINE

IS USED FOR CATARRHAL CONDITIONS OF MUCOUS MEMBRANE IN ANY PART OF THE BODY

Nasal, Throat, Stomach, Intestinal Rectal and Utero-Vaginal Catarrh

KRESS & OWEN COMPANY - 210 Fulton Street, New York

Sole Agents for Great Britain, THOS. CHRISTY & CO., 4—10 & 12 Old Swan Lane, London, E. C.

Examined and approved by the INSTITUTE OF HYGIENE, 34 Devonshire St., Harley St., W., where this preparation can be seen, and its properties and value can be explained.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXVI. WEDNESDAY, JAN. 1, 1908. No. 1.

NOTES AND COMMENTS.

A Happy New Year.

THE MEDICAL PRESS AND CIRCULAR cannot omit the duty, even if it wished to deny itself the pleasure, of wishing its increasing circle of readers a Happy New Year. It is unfortunate that in the public mind prosperity of the medical profession connotes a corresponding amount of illness among their patients. Such a fallacy is comparable only to that which assumes that because foreign countries are growing more prosperous Great Britain must be correspondingly poorer. Much illness may mean long doctors' bills, but it does not mean that they are paid, and more than a certain amount of illness means that the community is too much impoverished to support a well-to-do medical profession. *Per contra*, when there is general affluence and money is not "tight," patients more willingly resort to their medical advisers in the early stages of illness and for slight ailments, and not only are they saved much serious trouble thereby, but they are in a position to pay adequate fees, and to pay promptly. The depression resulting from the huge borrowings for the South African war, and from other causes, was felt by medical men in their practices as much as by wine merchants and stockbrokers, and we are, therefore, wishing the community no ill, but, rather, every blessing, when we express the hope that this year may be one of pleasure and profit to medical men.

Gaps in the Ranks.

THE year that is passed has been peculiarly prolific in the deaths of well-known members of the profession; some full of years and honours, others still bearing the burden in the heat of the day. Perhaps the greatest individual loss was that of Sir Michael Foster, who, though he had not practised medicine for many years, was only just below the rank of Darwin, Huxley, and Lyall in his scientific eminence, public reputation, and influence. But close on his heels followed Sir William Broadbent, who never spared his private interests where the weight so rightly attached to his name would be of service to the public. Then we have the great names of a former generation, Dr. Robert Barnes, the best known of [illegible], Mr. Timothy Holmes, as stern and [illegible] in the pursuit of duty as in the conduct [illegible]tion, and Sir Joseph Fayrer, who, as [illegible] Surgeon at Lucknow in the Mutiny, had [illegible] on his death-bed, and heard the pipes bray "The Campbells are Coming" in the nick of time. Dr. Sansom belonged to the last generation and our own, and the same may be said of Dr. W. H. Ransom, who graduated in 1850 and was F.R.S. for nearly forty years. The last fortnight of the year saw two great men pass away in Edinburgh, Professor Annandale and Sir Patrick Heron Watson, both of whom served the Modern Athens faithfully, well, and with distinction.

Other Losses.

GLASGOW lost a great figure and a rare personality in Sir William Gairdner; Manchester, a well-known teacher in Dr. Julius Dreshfeld; Dublin, an eminent surgeon in Mr. E. H. Bennett; Bristol, a leading physician in Dr. Markham Skerritt; Canada, a great man in Sir William Hingston; Paris, its best-known practitioner in the Hon. Alan. Herbert; Brighton, a generous ophthalmologist in Mr. C. J. Oldham; Norwich, a scholarly surgeon in Mr. C. W. Williams; Leeds, a popular figure in Mr. W. H. Brown; Belfast, the doyen of the local profession in Dr. Henry Murney; London, two conscientious workers in Dr. Montague Murray and Mr. Woodhouse Braine; and medical journalism, a well-known figure in Mr. T. H. Wakley. Of them and all others who have fallen by the way we can heartily say, *Requiescant in pace*!

Medical Inspection.

THE most important legislative Act as touching the medical profession, has been the establishment of medical inspection in schools as a compulsory duty on the part of education authorities. The principle of this Act has been warmly supported by medical men; indeed, it may be said to have originated and to have been carried through chiefly by them and their influence. The power for good in this measure is enormous, and we warmly welcome it. At the same time it is beset with pitfalls, and we make no apology for repeating what we have said several times already, that if the new duty is not properly understood and tactfully carried out, we may have all the old disgraceful scenes of the anti-vaccination movement re-enacted. Like the compulsory Elementary Education Act of thirty years ago, no one can say where it may lead to. It is obvious that if children are found with physical defects which are duly reported to the parents, and the latter neglect to have their children attended to, there will be indignation and outcry if any further steps are proposed. With many parents ignorant, many careless, and many prejudiced against the medical profession, difficulties are sure to arise, and these can only be kept within proper bounds by the most careful statesmanship, for there will not be wanting inflammatory agitators and demagogues to fan the flames amongst those persons who care more for political warfare than for the health of children.

Notification of Births.

WHATEVER difficulties there may be ahead with regard to the medical inspection of children in schools, there is no doubt that troublous times are ahead for those local authorities which adopt the Notification of Births Act. To the principle of that Act the profession have no objection; indeed again, it is greatly through their influence that it was brought to the front. That ignorant mothers may have the benefit of the instruction, help, and advice of a lady visitor of proper qualifications, where no medical man is in attendance, is likely to be of value in saving children's lives, but it is monstrous that any part of the duty of notifying such births should be laid on a medical man's shoulders. We leave aside the question of a fee altogether, and say it is an outrage on the liberty of the subject, the sanctity of professional confidence, and the traditions of Hippocrates which the profession respects, that medical men should be made by the State to play the spy on their patients. It wishes to do nothing of the kind, and if in spite of representations made to authorities they still adopt the Act, a policy of passive resistance is only to be anticipated. Medical men are not detectives, and they wish to pry on those who trust them less than on anyone. Moreover, the medical men are perfectly capable of instructing their patients in the rearing of children without the help of "health visitors" or sanitary inspectors. The duty of notification is a civil one which should devolve upon the parents, and them alone.

LEADING ARTICLES.

THE *STAR* AND THE MEDICAL PROFESSION.

THERE is a certain type of croaker existing in this world who regards all attempts at improving the status or repute of the medical profession as a hopeless task, or, at any rate, a task worth undertaking. We strongly disagree with that view. If it had not been for pessimists of the kind, medicine would probably be in a very different position from that which it occupies to-day. The old policy of allowing any street urchin to fling mud at medicine while medical men walked on with affected unconcern, has certainly not paid; its result has simply been that *every* street urchin knows he can fling mud with impunity, and a great many very decent and philanthropic persons believe doctors to be very dirty people because they see them continually bespattered. We have on several occasions of late replied directly to such attacks, and we have reason to know in some cases that a desirable effect has been produced. We believe in criticism ourselves, but we believe in fair and decent criticism. Nor is a little fun out of place, but fun should be used to show up an abuse or to correct a monstrosity. Merely to sneer at the inherent disabilities of a calling is as generous and as facetious as it is to sneer at a deaf boy at school or to trip up a man because he happens to be blind. We recently charged the *Star* with being "perhaps the most persistent reviler of medicine . . . that we have to contend with," and we spoke about the harm done to the poor by its maintaining that attitude. The *Star* has replied to that charge in a long leader, in which it contends that its attitude is not one of hostility to medicine, but only to vaccination and vivisection, and it expresses a wish that THE MEDICAL PRESS AND CIRCULAR would endeavour to see the point of view of the anti-vaccinator and the anti-vivisectionist, for, by making the case for medicine stand or fall by these practices, it is doing medicine a grave injury. We see, more clearly we fancy than our contemporary, the point of view of the classes indicated. But it is necessary to distinguish between the scientific and the political aspects of these questions, if a reply is to be made. To take vaccination first. The *Star* characterises this practice as a "disgusting cult," which we take to be a refined and polished method of intimating that vaccination is not a valuable protective measure against small-pox, but a kind of superstitious rite. If we are wrong in that supposition we are open to correction. It is impossible for any intelligent man who has studied the question to deny the protective influence of vaccination; it is as little open to question as the movement of the earth round the sun or the law of gravitation. The opposition to vaccination originated in certain ill-effects of the operation, mostly due to the entrance of pyogenic organisms through the wound in neglected children, and this opposition has been fanned by fanatical agitators for all it is worth. Any paper which kow-tows to those who deny the efficacy of vaccination to protect against small-pox lays itself open to a charge of ignorance on the one hand, or of a desire to tickle the ears of the ignorant on the other. If we turn to the political side of the question, there is not the slightest reason why a journal as an organ of opinion should not argue that compulsory primary vaccination is not the best means of protecting from small-pox a community containing many such agitators. That is a political question and an open one, and so long as fair argument is used nothing but respect to its supporters would be accorded by those who think otherwise. It is not fair argument, and it is a very silly argument, to assert, as the *Star* does in its article, that medical men support vaccination because of the fees it brings them. It is not fair, because vaccination does not bring the average practitioner a five-pound note a year, and small-pox used to bring him a great many score; it is silly because the only men who make any considerable income out of vaccination are the public vaccinators, and, human nature being what it is, to suppose that practitioners would support the giving of a privileged position and an assured source of income to a rival, for any other than a public motive, is to suppose a palpable absurdity. As to experiments on animals, the same considerations hold. The entire basis and progress of medicine since the dark ages of superstition are built on animal experimentation and the deductions based on it, and to impugn the value of such experiments is again the task of an ignoramus or an interested party. The moral question is apart. It is arguable, on moral grounds, that the lower animals were not given to man for his service; if so, a man who eats no meat or cheese, drinks no milk, wears no leather, drives behind no horse, accepts none of the benefits of medical science, opposes all field sports, and vigorously combats the castration of farm stock, may be considered honest when he opposes experiments on animals; but no other. To attribute cruelty where no cruelty exists, and to allege torture against men striving for the highest good of humanity, are cruel and cowardly acts. The Royal Commission whose sittings are now drawing to a close has offered every opportunity for any evidence of improper experiment by English researchers to be brought forward, and not a tittle has been forthcoming. But the *Star* and papers of its kind go far beyond opposition to vaccination and vivisection. They constantly insinuate that doctors "experiment" on patients in hospital, that unnecessary operations are performed, and that the most valuable remedies approved of by the profession are filthy and disgusting and useless; all, of course, without a shadow of evidence. It is an easy *rôle* to play, and when the public interest is dragged in as a motive, it seems plausible enough; but all medical men who work among the poor know the result is misery, and disease, and reliance on boomed and worthless panaceas till the period when judicious treatment might have saved is passed. There is a far greater and more potent tyranny than the tyranny of any law, and that is the tyranny of prejudice and ignorance; this tyranny the medical profession seeks to remove and the *Star* delights to foster.

WALKING AS AN EXERCISE.

MANY folk are inclined to exclude walking from the group of exercises associated in their minds with the word "athletics." To them the term in question means rowing, boxing, jumping, wrestling, riding, football, cricket, tennis, and a host of other sporting recreations—anything, in a word, but the first that mankind acquires at the outset of his brief sojourn upon the earth. Yet it may be questioned whether walking is not the most healthful, as it is certainly the most readily available and least costly of all forms of physical recreation. Carried to an excess, like most other sublunary things, it is likely, more or less, to defeat its own purposes. For instance, no one imagines that a postman's span of days is notably lengthened owing to the fact that he systematically covers a long distance every day of his working life while walking his rounds. As a rule, one associates the average postman with the conception of a spare, wholesome man, but certainly not with any great bodily development or with any special tendency towards longevity. It would be interesting, indeed, to have some statistics on this point, if such be forthcoming, either from St. Martin's-le-Grand or from Somerset House. So far as the man in the street is concerned, it is pretty certain that town dwellers are apt to ride in cab, car, omnibus, or railway-carriage, when it would be infinitely better for their health were they to walk. The chief object nowadays is to save time, and it is difficult or impossible for a busy man to find leisure for walking from point to point, when golden moments may be saved by resorting to the simpler methods of transit that are the main-spring of modern civilisation. Under such circumstances it is somewhat reassuring to note that a vast commercial centre like Manchester is able to support a flourishing pedestrian club. A thirty-mile walk was one of the prominent features in last season's programme, but that was put in the shade by a well-patronised jaunt from Birmingham to Bristol, a distance of some 203 miles, by way of the picturesque Wye Valley. Such clubs are well worth support throughout the kingdom. Even in the largest cities it is always feasible to fix the starting-point somewhere in the outskirts, so as to be clear of bricks and mortar from the outset. Walking is an exercise, that, from its nature, is adapted to all sexes and to all ages, so that young men and old may therein join together in a healthy, rational, and altogether innocent form of recreation. Twenty miles should be readily within the compass of every robust adult person as a reasonable day's march. Thirty miles is a full but not excessive limit for a strong man in good training, although forty miles is the traditional allowance fixed for him in the popular mind. From the medical point of view, walking as a regular exercise can hardly be too highly commended. Writers on longevity have again and again shown that persons attaining old age are almost invariably persons of active habits who have been given all their lives to walking rather than to riding. It may, indeed, be laid down as a primary principle of health that a healthy man ought, wherever possible, to walk some eight or ten miles daily. Not only is that form of bodily activity available for the strong and hearty, but it is also applicable, and sometimes beneficial, to the weakly and ailing. A patient suffering from some form of heart disease, for instance, may keep his circulatory apparatus in good order by systematic walking exercise, where he would be strictly debarred from all kinds of violent physical exertion. In giving advice of this kind, the medical profession is acting in its usual disinterested manner, for it is clear that the more healthy persons become as the result of walking the less will they require the services of medical men. It is to be hoped that the pedestrian clubs will come to the rescue before walking has become a lost art, and that they will be able to assert the rights of passenger locomotion on country roads which are at present seriously threatened by the ceaseless rush of the aggressive motor.

CURRENT TOPICS.

A Hospital without X-Rays.

NOWADAYS any general hospital not furnished with an X-ray installation may be regarded as much behind the times. There are many cases, both medical and surgical, in which a skiagraph examination is absolutely essential to the formation of a correct diagnosis, whereon the life of a patient obviously may hinge. The Guest Hospital, at Dudley, appears to be in the ill-equipped position in point, according to the evidence forthcoming at a recent inquest. A child of four swallowed a flat whistle the size of a halfpenny. A local medical man felt the foreign body in the throat, but was unable to remove it, and sent the child to the hospital mentioned. The senior house-surgeon failed to detect anything in the œsophagus, but the child gradually sank and died. He stated that no X-ray apparatus was in the hospital, and admitted that no attempt was made to procure a skiagraphic examination elsewhere. A post-mortem examination revealed the whistle impacted in the pyloric orifice of the stomach, and death was attributed to starvation. Most medical men will be inclined to agree with the Coroner that under the circumstances some more drastic step should have been taken to diagnose the exact state of affairs, especially in view of the precise medical information forthcoming in the first place as to the presence of a foreign body. Perhaps some philanthropic person may now be induced to supply an X-ray installation to the institution.

National Hysteria.

THOSE who maintain that the English national character is changing and becoming more like that proverbially associated with our neighbours across the Channel certainly have some argument on their side. It would seem, indeed, as if the English reputation for stolidity were bound to disappear, and though stolidity may not be an entirely lovable quality, it was more estimable than the excitability which is taking its place. It was during the Boer War that attention was in our time first directed markedly towards this apparently new trait in the English people, and it was then excused as only appearing at moments of relief from great strain. It is true, at any rate, that London was within a short time thoroughly ashamed of the way in which it celebrated the relief of Mafeking, and of some other scenes of similar kind. But on various occasions since then the populace of London has shown the same lack of sanity which characterised it during the war. In particular, the interest exhibited in sensational criminal trials is an unpleasant manifestation of public want of balance. The hysterical excitement surrounding the case known as the Camden Town murder is the latest example. In this case, a man of unattractive personality—to put it mildly—by his own lying and cowardice, finds himself arraigned on the capital charge. There is obviously lack of evidence against him, and the jury does its duty; the man comes out of Court a mob-hero. He is declared "a jolly good fellow," and narrowly escapes being chaired through the streets by a crowd of several thousands assembled to do him honour. His life appears in the weekly papers; he is engaged to give "shows" at music-halls; and for the nine days that elapse before he sinks into his native obscurity he is the hero of London. The whole incident is discreditable to the good sense of the community.

Election of a Hospital Matron.

There has been a very unnecessary fuss made in the Irish papers regarding the recent election of a matron at the Meath Hospital in Dublin. It appears that the successful candidate was elected by a very small majority of the committee. She had been trained at the hospital and had on many occasions acted as matron. The Meath Hospital is peculiar in being the County Infirmary of the County Dublin, and it therefore receives a grant from the County Council, three of whose members are appointed to the committee. Two of these gentlemen, being dissatisfied with the result of the election, reported in set terms to the County Council that the best qualified candidate had not been chosen, and the County Council, accepting their statement, passed a resolution of protest. The action of the County Council in accepting an *ex parte* statement, and acting on it, is injudicious in the highest degree, and injurious to the institution concerned. There is no suggestion that the members of the Hospital Committee acted otherwise than *bonâ fide* and within their legitimate discretion in their choice of a candidate, and, that being so, we can hardly see any justification for the protest of the County Council. It is not the first time, however, that certain members of that body have shown a hectoring disposition towards the management of the Meath Hospital, a disposition which hardly conduces to the efficient working of the Hospital.

The Health of Brass Casters.

The craft of the brass-casters is exercised by a far larger section of the labouring community than is generally recognised. Nor have the peculiar dangers to health incident to its exercise hitherto obtained a fair share of attention at the hands of sanitarians. Poisoning from that source is of a peculiar character, and includes the well-known form of spurious ague connected with the occupation. A serious effort is now being made to include the industry within the scope of industrial sanitary control. Some months ago the National Society of Brass-workers approached the Home Secretary on the point, and the result was the issuing of an order by the Home Office to the effect that, subject to public enquiry, the noxious fumes in brass-casting should be taken away at the point of origin, and that instead of cold water and basins to wash in, as now provided, there should be hot water, with towels, soap, and nail brushes. Opposition to this order has been offered by employers in Glasgow, Edinburgh, Wales, Ireland, and all parts of England, including London. It is interesting to learn, on the other hand, that, after conference, the Birmingham employers and workpeople have decided to apply the new rules, subject to certain modifications. A public inquiry is at present being held in Birmingham by Mr. Wills. As a matter of fact, the trade concerned is one of considerable magnitude, and the question of its sanitary regulation involves issues of vital importance to all concerned, either directly or indirectly, in the maintenance of a high standard of national health.

A Herbalist and Oil of Juniper.

Some serious matters were recently raised in the course of an inquest held at Walkley, near Sheffield, upon the body of a married woman, thirty-eight years of age. From the evidence it was shown that deceased went to a herbalist, named Emily Rose, who prescribed and sold her oil of juniper, to be taken in 15 minim doses, ostensibly for the benefit of the kidneys. As the dose of this highly irritant drug is from 1 to 4 minims, it is hardly to be wondered that the poor woman was seized subsequently with violent vomiting, from which she rapidly sank and died. The medical man who attended deceased testified to her admitting having taken a quantity of oil of juniper, to which he attributed her death. The woman herbalist said she did not know the stuff was poisonous, and admitted she did not know the juniper dose and that she had put no label on the bottle. The jury returned a verdict that death was due to an overdose of oil of juniper, and that it was taken for the purpose of bringing on a miscarriage. Quite apart from the possible criminal element in this case, it seems to us nothing less than a public scandal that ignorant persons should be allowed to deal in deadly drugs in this fashion, acting as they do under a semi-medical guise which imposes only too readily on the credulity of the vulgar. We trust the local police will in future keep a close eye upon the proceedings of Emily Rose, of Walkley.

The Licensing of Cowhouses.

The importance of preserving the national milk supply pure and untainted has been more than ever recognised since the formal scientific recognition of human and bovine tuberculosis as diseases of identical origin. Before any effectual sanitary control can be established it will undoubtedly be necessary to obtain fresh legislation, for instance, in the direction of amalgamating and consolidating the process of rural and urban local authorities, and, if necessary, of compensating owners of condemned tuberculous cattle. At the same time, it is well worth calling the close attention of our urban medical officers of health to their present powers in the control of cowhouses, with a view to safeguarding still further the health of the cows housed therein, to the consequent advantage of consumers. As things go, it is significant that many regulated town dairies are superior to those in country places, where the special Acts do not apply. That defect might be readily made good by a short Act extending and adopting the provisions of the Dairy and Cowsheds Order so as to include town and country in one compulsory scheme. In towns where the regulations are enforced a great amount of protection is thereby afforded to the community. The fact that in London alone no fewer than 300 cowhouses are under careful inspection and license suggests that an immense amount of preventable disease is almost certainly excluded from the milk by the enforced observance of certain standards of cubic space, ventilation, drainage, and cleanliness.

Alcohol in Hospitals.

The average consumption of alcohol in hospitals may be regarded, on the whole, as a fair test of the estimation in which alcohol is regarded as a remedial agent by the medical profession. There can be little doubt that the total hospital consumption has fallen greatly within the past few years. It is a point of no little significance to note that in some instances an additional impulse towards denunciation has come from working men who have been supporters of those institutions. That interesting fact, for instance, was recently mentioned in connection with the Swansea Hospital. Dr. Rawlings, who dealt recently with the medical aspects of alcohol, mentioned that in that particular Institution the bill for alcoholics, thanks chiefly to the working-men representatives, sank from £154 3s. in 1904-5 to £75 in 1906. The amount per occupied bed in 1840 was £2 3s. 7d., which had dropped to 4s. 7½d. in 1907. These figures probably represent roughly the degree to which alcohol has dropped out of the medical armamentarium, in spite of the recent curious attempt to rehabilitate its claims by the notorious manifesto launched upon the public by a self-constituted jury of medical men. Another statement made by Dr. Rawlings emphasises the advance of the temperance movement amongst the medical profession, namely, that when he signed the pledge in 1871 he was the only total-abstaining practitioner in the town, whereas there were now no fewer than eight.

Responsibility of Surgeons for Anæsthetics.

The question of the apportionment of responsibility in the administration of anæsthetics has recently been raised by Dr. F. J. Waldo, the City Coroner. Hitherto the generally accepted view is that the operating surgeon accepts full responsibility, but it is by no means clear what is the strictly legal aspect of the matter. The point has not been raised in the law courts, and until a test case is brought any operating surgeon may find himself faced with an action for damages by the litigious friends of some patient who has unhappily died on the operating-table. There is obviously a good deal to be said on both sides of the question. In former days the danger arose from the surgical procedures, whereas now the latter are often outweighed by the risks of anæsthesia. As a matter of fact, arrangements are often left entirely to the surgeon, who brings his own anæsthetist to the house, under which circumstances it would seem somewhat difficult to absolve him of all responsibility. In some operations, moreover, the surgeon never relaxes his supervision over the general anæsthetic condition of the patient, and should any emergency arise, he is apt to assume full direction of all remedial measures. In a recent inquest held upon a death at Guy's Hospital, the surgeon in charge accepted full responsibility for the anæsthetic which proved fatal. He further admitted that the operation (for the excision of a goitre) was one of special danger from an anæsthetist's point of view, but he had, notwithstanding, handed over the case to a newly qualified house surgeon instead of to one of the expert anæsthetists attached to the hospital. The whole matter is one worthy of careful attention, as, failing some definite solution, operating surgeons may be exposed not only to civil actions for damages, but also to criminal prosecutions, where a death under anæsthetics is associated with any lack of reasonable skill and precaution. For our own part, whatever the law may say, we are inclined to allot a share of the responsibility to the surgeon.

PERSONAL.

Dr. Ludwig Freyberger has been made a magistrate for the County of London.

Dr. C. E. Underhill has been re-elected President of the Royal College of Physicians of Edinburgh.

A bust of the late Mr. George Herring will be unveiled at the Mansion House at the next meeting of the Metropolitan Hospital Sunday Fund.

Lord Farquhar took the chair at the eighth annual meeting of the Presidents of the League of Mercy, held at St. Thomas's Hospital, on December 20th last.

Among the passengers by the White Star Liner "Oceanic," which arrived at Southampton on December 24th, was Dr. J. F. Leys, the Superintendent of the Colon Hospital.

The Army Council has approved as additional members of the staff of Queen Alexandra's Military Hospital:—Surgeon-Major-General A. F. Bradshaw as Consulting Physician, and Lieutenant-Colonel P. J. Freyer as Consulting Surgeon.

Sir Jas. Crichton Browne, M.D., F.R.S., and Drs. W. J. Simpson, J. W. Slaughter, and R. Parker Young have been elected members of the "Social Economy Committee" of the Franco-British Exhibition to be held in London this year.

Dr. R. J. Collie has been placed on the Commission of the Peace for the County of London.

At the Royal College of Surgeons of England on December 23rd, Mr. C. R. Hewitt, who for the past 22 years has held the post of assistant in the college library, received a presentation. The subscribers numbered some 75 friends, on whose behalf Professor William Osler, F.R.S., handed to Mr. Hewitt a piece of plate, suitably inscribed, and a cheque.

The opening lecture of the Mount Vernon Hospital Post-Graduate Course will be given by Sir Thomas Clifford Allbutt, K.C.B., F.R.S., at 7, Fitzroy Square, W., on January 9th, at 5 p.m. The subject of the lecture will be "Angina Pectoris."

The sum of £150,000, left by the late Mr. Edward Wilson to the city of Melbourne, is to be used for building a new hospital.

A CLINICAL LECTURE
ON
THE DIET OF THE AGED. (a)

By HARRY CAMPBELL, M.D., F.R.C.P.Lond.,

Physician to the West End Hospital for Nervous Disease.

Gentlemen,—The subject I propose to speak on to-day is the diet of the aged. It admits of being dealt with in a very comprehensive way, but that would require several lectures, and it is impossible to summarise it in a comparatively few words. First, a few remarks on the teeth. We are familiar with the toothless gums of old people. Edentulous man was probably unknown before the cookery period, because man had to chew his raw vegetable food so much in those times in order to break up the cellulose network, that his teeth had abundant exercise; and I feel sure they got worn down to the level of the gums. There are no people of that kind now, for even the most savage understands cooking. When the teeth of these men were worn down to the level of the gums, it practically meant that they could no longer live. Animal food does not require much mastication, but raw vegetable food does; and if a man had worn his teeth down to the gums, he had either to be carnivorous, or die. Still, he may have done something in pounding his food by means of a stone. Vegetable food which is cooked does not need nearly so much breaking up. But I do not think that early cooking man, before the agricultural period, attained to the edentulous stage. I have examined many skulls of very primitive people, but I do not remember to have come across one in which the teeth had been shed from senile absorption of the alveolar processes. When we come to the late agricultural stage we find it a very interesting one in regard to the teeth, because there is a great amount of soft vegetable food, so that man was able to subsist practically with no teeth at all. The result of eating this soft vegetable food has been to cause a terrible deterioration of the teeth, a fact which does not seem to be realised by even all dentists yet.

With regard to the masticating capacities of the edentulous, when a person loses his teeth the gums harden, and he is able to deal with his food fairly well, as a whole, though tough overdone meat would naturally bother him. And such a person cannot deal with crusts, but he is able to soak them in his tea or coffee. An edentulous person can deal with his food better than can a person with bad teeth; it may be that none of his teeth oppose properly, and they therefore prevent the gums from coming together to break up the food.

There is next the question as to the advisability of providing old edentulous people with false teeth. I have heard it argued that false teeth are not good for old people, because absence of teeth compels the eating of only simple food, the loss of the teeth being an indication for them to return to the food of infancy. But on examination this argument is found to have no basis; because if Nature means anything by edentulism, she means that the time has come for the person to die, because under natural conditions such a person would not be able to obtain sufficient nourishment. Absence of teeth does not prevent the person from eating too much, or from eating improper food, whereas the presence of teeth does enhance the person's masticatory power. So whenever a person can be fixed up with teeth, he or she should have them. I believe dentists say that people should not wait until all the teeth are out before having artificial teeth, but should be fitted with artificial dentures directly the teeth come out; because when they are all out he then finds less difficulty in wearing a plate.

I now want to say something about what I call the ideal diet. From the dietetic point of view, you may divide human beings into those who eat to live, and those who live to eat. Taking an extreme instance of each of those, I would say that a person who eats to live is one who eats moderately, and takes simple, plain foods. He eats no more than is necessary for physiological requirements. Assuming the food to contain the proper ingredients, he eats the minimum quantity which will sustain him at the least weight consistent with the best health of which he is capable. Any food in excess of that cannot do him any good, and it may do much harm. The next essential of an ideal diet is that the food should be simple. By that I mean that it should consist of bread, ordinary dairy produce, any kind of animal produce, provided it is simply cooked, and simple plain pudding with fresh fruit. And of course there should be simple vegetables plainly cooked, a little salt and a little mustard, and tea and coffee, but no condiments and no alcohol. The third essential is, that all the starchy foods should be thoroughly masticated, to break up the cellulose network, which is very indigestible, and liberate the contained food stuffs. During that process the starch is largely digested in the mouth into dextrine and maltose. Therefore in the case of people with weak digestions, I insist that they should spend a long time in masticating their starchy foods, and tell them to take their starchy foods in a form which compels mastication; they should get a good hard crust or a plain biscuit, and chew that until it liquefies in the mouth. That will more efficiently predigest the starch than any of the patent methods or foods. It is better that a person should digest his starch in the laboratory of his own mouth than that he should have it digested for him. Now that the cellulose meshwork is broken up by cookery, the mastication is to digest it in the mouth. Debilitated people should have their animal food minced, but otherwise I do not care whether animal food is chewed or not. Early man conformed to these three essentials; he ate moderately in quantity, on the average, simply because he was obliged to. No doubt at times he gorged himself, and an occasional gorge does no one harm—it may even do good. But he could not do that much, for he had to spend his time in hunting animals for food, and searching for roots and berries. And you must reflect what active lives they lived, and such people can take a good deal of food without over-eating. And of course he conformed in the matter of simplicity, because he had not many foods to choose from. Practically no form was refused by him—game, shell-fish, slugs, flies, ants, rats, and lizards. He had also to conform in regard to starchy foods, because raw vegetables, other than luscious fruits and young shoots had to be considerably masticated.

(a) Delivered at the Medical Graduates' College and Polyclinic, on December 4th, 1907.

Now I come to the application of these remarks to the diet of old people. Had there been time, I would have liked to have said something about the diet of those who live to eat. The contrast would have been very dramatic between what we have been speaking about and the diet of the person who is both epicurean and gourmand, who not only aims at eating nice things but eats enormous quantities.

A few words about the passage of food through the body. In that passage the food goes through three phases. First, that of digestion, which you may say is the conversion of the food into liquid nutrient plasma, which is capable of being assimilated by the tissues. When it comes into contact with the cells of the tissues in undergoes other changes, which we refer to as metabolism. And finally, after the food has been dealt with by the tissues, certain waste products are given out and eliminated. These three functions are most active in early life. But with advancing years these three functions tend to wane. From about 45 years onwards, a man begins to feel that there are many things he could eat in the past but which he now feels disagree with him. That is often because he has learned to recognise the relation between cause and effect. Metabolism is also less active; not only is the food less digested, but it is not metabolised so actively. It may be that the food stuffs are not burned off so efficiently, and there may be imperfectly oxidised products circulating in the blood, giving rise to "rheumatic" and other pains. But the question whether immoderation in food causes evil results chiefly by leading to indigestion or chiefly by giving the tissues too much work to do in the way of metabolism, is a very interesting and difficult question. I have been in the habit of arguing that if a person can only digest his food completely in the stomach and intestines and liver, so that there is poured through the hepatic veins into the general circulation food in a form very presentable to the tissues, that there should not be much harm from it; and that the evils of improper diet refer essentially to the digestive system, and comparatively little to the metabolic system. In Graves' disease, for instance, the metabolism is very active, there is an increased output of carbonic acid and urea, and the cells burn off very rapidly. So it may be that the evils resulting from indiscreet feeding depend not only on the inability of the digestive system to cope with the food but inability of the tissues to cope with it. I think the first of these factors is the more important.

In old age the digestion is still weaker, and the metabolic activity of the tissues less pronounced. The excretion also begins to be defective. The cells of the mucous membrane of the stomach and intestines are found to be largely replaced by fibrous tissue. Moreover, in old age the vital force flickers, and the organs of excretion begin to fail, though not markedly until the senile phase is entered upon. It follows from this that the older a person gets, the more urgent is it for him to, as for as possible, confine his diet to the ideal which I have mentioned; for he has not the reserve fund of younger periods, and cannot, without harm, indulge in all sorts of made-up dishes. We sometimes meet with people who do not seem to have any reserve force, and who, from childhood, could not take any liberties with their food without suffering for it. On the other hand we find wonderful old people who seem able to eat right through a century, but they, of course, are prodigies. It is a sound general rule that the older a person is the more should he conform to the ideal diet. Otherwise I do not think that the diet of the aged should differ from the diet of the young. Of course if a person is very feeble you can predigest his food a little.

I will mention a case or two. A gentleman, 66 years of age, came complaining of nose-bleedings, flushings of the head, and giddiness. He had a high tension pulse, and a little albumen in his urine. He fell down in one of these attacks of giddiness. He was eating about four times as much as he ought to. By cutting down his food—chiefly his starches and sugars, to about one-fourth, and cutting off his alcohol, the whole of his symptoms disappeared. The cutting down of meat is not so important as reducing starch and sugar. Very primitive man ate more animal than vegetable food, and the only sugar he had was a little honey. Another type of case in which you do an enormous amount of good by cutting down the food is bronchitis. If an obese elderly person has bronchitis, do not hesitate to practically starve him.

I now want to say a word about the diet of workhouses, a very interesting subject. I have visited two or three workhouses, and find that these old people eat very well. In one of the workhouses they grind their own corn. I show you one small loaf, weighing ¼lb. of wholemeal, and one the same weight, consisting of one portion of wholemeal to two portions of white. Each person eats five of those every day, and with each meal they have a pint of tea and ½oz. of margarine—which is quite as nutritious as butter—twice a day. In the middle of the day, at Marylebone, they have ¼lb. of meat, or bacon, and 12ozs. of vegetables, consisting of 8ozs. of potatoes and 4ozs. of greens. There is also sugar and milk with the tea. Once a week there is stewed fruit, and once a week pudding. No alcohol at all. In answer to inquiries, I learned that they suffer very little from indigestion. In reply to my question as to whether they suffered much from constipation, I was told that among the 2,000 inmates they do not have to give more than 20 doses of aperient in the day. That means only 3½ doses per individual in the entire year, which is remarkable, and shows what a simple dietary and regular meals will do. I also learned that in later life, when the reproductive system is atrophied and the fires all burnt out, that the women are more catabolic than the men. I was fortunate in having this patient to see me this morning, and, as he well illustrates the prolonged activity of the digestive function, I asked him to come and show himself to you. I have had him under observation for a long time, and he will soon be in his 92nd year. We are all proud that he is a Britisher. Between eleven o'clock and coming here he has been almost continuously walking about London. He has been a head gardener 50 years. At the age of 80 he applied for fresh employment, but when they learned his age they would not take him. He has been at various places in the country, eating well of the same food as other people, and feeling well; but since he returned to London he has been having a little indigestion.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Arthur Whitfield, M.D., F.R.C.P., Professor of Dermatology in King's College, Physician for Skin Diseases to King's College and to the Great Northern Central Hospitals. Subject: "Psoriasis: Its Clinical and Microscopical Characters, Diagnosis and Treatment."*

CLINICAL LECTURES FOR 1908.

We have been favoured by promises of Clinical Lectures from the following Hospital Teachers and Post-Graduate Lecturers, to whom we tender our best thanks:—

Wm. Alexander, M.D., R.U.I., F.R.C.S., Lecturer on Clinical Medicine, University of Liverpool.

Sir C. Ball, F.R.C.S.I., Regius Professor of Surgery, Dublin University, Surgeon to Sir P. Dun's Hospital.

Hy. Gilbert Barling, M.B., Lond., F.R.C.S., Surgeon to the Birmingham General Hospital and Dean of the Faculty of Medicine.

Sir James Barr, M.D., F.R.C.P., Lond., Physician, Royal Infirmary, Liverpool.

John Bland-Sutton, F.R.C.S.Eng., Surgeon to the Middlesex Hospital and to the Chelsea Hospital for Women.

George L. Chiene, M.B., Ed., F.R.C.S., Assistant Surgeon, Royal Infirmary, Edinburgh, Senior Demonstrator of Surgery, University of Edinburgh.

E. Scott Carmichael, M.B., Ed., F.R.C.S., Assistant Surgeon Royal Hospital for Sick Children, Surgical Registrar, Royal Infirmary, Edinburgh.

Harry Campbell, M.D., Lond., F.R.C.P., Lond., Physician to the North-West London Hospital and to the West End Hospital for Nervous Diseases.

Albert Carless, M.B., Lond., F.R.C.S., Surgeon to King's College Hospital, Professor of Surgery in King's College.

Edred M. Corner, B.Sc., Lond., F.R.C.S., Surgeon in Charge of Outpatients, St. Thomas's Hospital, Senior Assistant Surgeon to the Hospital for Sick Children.

Sir J. Halliday Croom, M.D., Ed., F.R.C.P., Cons. Gynæcologist. Royal Infirmary, Edinburgh; Professor of Midwifery, University of Edinburgh.

J. Debove, M.D., Doyen de l'Académie de Medécine, Paris, Physician to the Beaujon Hospital.

John Dundon, M.B., F.R.C.S., Eng., and F.R.C.S.I., Professor of Materia Medica and Therapeutics, Queen's College, Cork, Surgeon Mercy Hospital, Cork.

Jakob Erdheim, M.D., Professor of Clinical Medicine, University of Vienna.

Wm. Ewart, M.D., Cantab., F.R.C.P., Lond., Senior Physician to, and Joint Lecturer on, Medicine, St. George's Hospital.

Patrick J. Fagan, F.R.C.S.I., Surgeon to St. Vincent's Hospital.

Robt. Alex. Fleming, M.D., F.R.C.P., Lecturer on the Principles and Practice of Medicine in the Edinburgh Medical School; Assistant Physician to the Royal Infirmary.

John Magee Finny, M.D., F.R.C.P.I., Past-President R.C.P.I. King's Professor of Practice of Medicine, School of Physic in Ireland' Physician to Sir P. Dun's Hospital.

Jas. S. Fowler, M.D., F.R.C.P., Physician, Edinburgh Royal Hospital for Sick Children.

Andrew Fullerton, M.D., F.R.C.S.I., Assistant Surgeon, Belfast Hospital for Sick Children, Assistant-Surgeon Royal Victoria Hospital, Belfast.

Arthur E. Giles, B.Sc., Lond., M.D., F.R.C.S.E., Surgeon, Chelsea Hospital for Women, and to the Prince of Wales Hospital.

J. Dundas Grant, M.D., Ed., F.R.C.S., Eng., Surgeon to the Central London Throat and Ear Hospital, and to the West-End Hospital for Nervous Diseases.

Geo. L. Gulland, M.D., Ed., F.R.C.P., Assistant Physician to the Royal Infirmary, Edinburgh, Physician to the Victoria Hospital for Consumption.

Alex. Haig, M.D., Oxon, F.R.C.P., Lond., Physician to the Metropolitan Hospital and to the Royal Waterloo Hospital for Children.

W. Sampson Handley, M.D., M.S., Lond., F.R.C.S., Hunterian Professor of Surgery, Royal College of Surgeons, Assistant Surgeon to the Middlesex Hospital.

Chas. J. Heath, F.R.C.S., Surgeon to the Throat Hospital, Golden Square, President of the West Kent Medico-Chirurgical Society.

Francis Thomas Heuston, M.D., F.R.C.S.I., Senior Surgeon. Adelaide Hospital, Consulting Surgeon, Coombe Lying-In Hospital and Rotunda Hospital, Dublin.

Peter Horrocks, M.D., F.R.C.P., Lond., Senior Obstetric Physician, Guy's Hospital, Lecturer on Obstetrics and Diseases of Women, Guy's Hospital.

Robt. Hutchison, M.D., Ed., F.R.C.P., Lond., Assistant Physician to the London Hospital and to the Hospital for Sick Children.

Theo. B. Hyslop, M.D., Ed., M.R.C.S., Resident Physician Superintendent of Bethlem Royal Hospital, Lecturer on Mental Diseases, St. Mary's Hospital.

A. Jaquet, M.D., Professor of Therapeutics to the Faculty of Medicine, Paris.

T. Percy Kirkpatrick, M.D., F.R.C.P.I., Physician and Clinical Registrar, Steeven's Hospital, Dublin.

Frederick W. Kidd, M.D., Gynæcologist to the Meath Hospital, late Master Coombe Hospital, Dublin.

Denis Kennedy, F.R.C.S.I., Surgeon, Jervis Street Hospital and Children's Hospital, Temple Street, Dublin.

Charles R. B. Keetley, F.R.C.S., Eng., Senior Surgeon, West London Hospital.

Chas. B. Lockwood, F.R.C.S., Surgeon to St. Bartholomew's Hospital.

P. W. Maxwell, M.D., F.R.C.S.I., Surgeon to the Royal Victoria Eye and Ear Hospital, Dublin.

G. E. Pugin Meldon, M.D., F.R.C.S.I., Surgeon, Westmorland Lock Hospital, Dublin.

Elie Metchnikoff, M.D., F.R.S., Professor at the Pasteur Institute Paris.

Thos. K. Monro, M.D., M.Ch., F.F.P.S., Glas., Physician and Clinical Lecturer, Glasgow Royal Infirmary, Professor of Medicine in St. Mungo's College.

Herbert C. Mooney, M.B., F.R.C.S.I., Ophthalmic Surgeon, Children's Hospital, Dublin, Assistant Surgeon and Curator of Museum, Royal Victoria Eye and Ear Hospital.

Sir John Wm. Moore, M.D., F.R.C.P.I., Representative on General Medical Council, R.C.P.I., Senior Physician, Meath Hospital, Past-President Royal College of Physicians of Ireland.

Alex. Morison, M.D., F.R.C.P., Lond., Physician, Gt. Northern Central Hospital.

Wm. Murrell, M.D., F.R.C.P., Lond., Physician to the Westminster Hospital.

Sir Thomas Myles, M.D., B.Ch., Dub., F.R.C.S.I., Surgeon Richmond Hospital, Dublin.

David Newman. M.D., F,F.P.S., Glasg., Surgeon to the Glasgow Royal Infirmary.

H. Oliphant Nicholson, M.D., Aberd., F.R.C.P., Ed., Assistant Physician to the Edinburgh Maternity Hospital.

D. J. O'Connor, M.D., F.R.C.P.I., Physician, Mercy Hospital, Cork Physician, Cork Lying-in Hospital.

R. W. Philip, M.D., Ed., F.R.C.P., Physician to the Royal Victoria Hospital for Consumption, &c., Senior Assistant Physician to the Edinburgh Royal Infirmary.

John Poland, F.R.C.S., F.L.S., Senior Surgeon to the City Orthopædic and the Miller Hospitals, Consulting Surgeon to the St. Pancras and Northern Dispensary.

D'Arcy Power, M.A., Oxon., F.R.C.S., Surgeon to and Lecturer on Surgery at St. Bartholomew's Hospital, Consulting Surgeon to the Victoria Hospital for Children.

A. Maitland Ramsay, M.D., F.F.P.S., Glas., Surgeon, Ophthalmic Inst., Glasgow.

Prof. A. W. Mayo Robson, F.R.C.S., Hunterian Professor Royal College Surgeons, Eng.

Robert J. Rowlette, M.D., Lecturer in Pathology, Queen's College, Galway, Pathologist Steeven's and Rotunda Hospitals, Dublin. President Dublin University Biological Association.

J. S. Risien Russell, M.D., F.R.C.P., Lond., Physician to University College Hospital and to the Hosp. for Paralysis and Epilepsy.

R. Rehn, M.D., Professor of Surgery in the University of Berlin.

Geo. H. Savage, M.D., Lond., F.R.C.P., Lond., Consulting Physician for and Lecturer on Mental Diseases, Guy's Hospital.

Cecil E. Shaw, M.D., Assistant Surgeon, Belfast Ophthalmic Hospital, Consulting Oculist Alexander Hospital, Lecturer in Ophthalmology, Queen's College, Belfast.

Sydney Stephenson, M.B., C.M., F.R.C.S.E., Ophth. Surgeon, Evelina Hospital.

J. Lindsay Steven, M.D., F.F.P.S., Glas., Physician and Lecturer on Clinical Medicine, Glasgow Royal Infirmary.

Wm. St. C. Symmers, M.B., Musgrave Professor of Pathology, Queen's College, Belfast.

Sir William J. Smyly, M.D., F.R.C.P.I., Ex-President Obstetrical Section Royal Academy of Medicine, Ex-President R.C.P.I., Gynæcologist to Adelaide Hospital, Late Master, Rotunda Hospital, Dublin.

Jas. W. Russell, M.A., Cantab., M.D., F.R.C.P., Lond., Physician to the Birmingham General Hospital, Consulting Physician to the Midland Ear and Throat Hospital.

Geo. F. Still, M.A., Cantab., M.D., F.R.C.P., Lond., Physician for Diseases of Children, King's College Hospital, Assistant Physician, Hospital for Sick Children.

Geo. A. Sutherland, M.D., Ed., F.R.C.P., Lond., Physician to the North-West London Hospital, Physician to the Paddington Children's Hospital, and to the City Orthopædic Hospital.

Edward H. Taylor, M.D., F.R.C.S.I., Professor of Surgery, Trinity College, Dublin, Surgeon to Sir P. Dun's Hospital, Dublin.

William Taylor, M.B., F.R.C.S.I., Surgeon to Meath Hospital, Visiting Surgeon, Cork Street Hospital, Dublin.

Nestor Tirard, M.D., Lond., F.R.C.P., Lond., Professor of the Principles and Practice of Medicine in King's College, Physician to King's College Hospital.

Wm. Turner, M.S., Lond., M.B., F.R.C.S., Surgeon to, and Lecturer on Minor Surgery at, Westminster Hospital.

William I. de C. Wheeler, M.D., F.R.C.S.I., Visiting Surgeon, Mercer's Hospital, Dublin.

Arthur J. Whiting, M.D., M.R.C.P., Lond., Dean of the N.E. London Post-Graduate College, Physician to the Prince of Wales Hospital, and Mount Vernon Hospital.

Arthur Whitfield, M.D., F.R.C.P., Lond., Professor of Dermatology in King's College, Physician for Diseases of the Skin to King's College Hospital.

Andrew Wylie, M.D., C.M., Assistant Surgeon, Central London Throat, Nose, and Ear Hospital.

ORIGINAL PAPERS.

INHERITED SYPHILIS. (a)

By R. Clement Lucas, B.S., M.B.Lond., F.R.C.S.,

Consulting Surgeon to Guy's Hospital and to the Evelina Hospital for Children.

I have had the honour of opening this discussion thrust upon me by the unanimous vote of the Council as a penalty for certain criticisms I ventured to make on former discussions to the effect that the length and learning displayed in the opening addresses—sometimes five or six in number—left neither time nor opportunity for subsequent debate. I ventured to think the opening should be more suggestive than dogmatic, and terse rather than discursive. As a consequence, I am here to represent a phrase rather than a faculty, and the burthen of presenting new ideas and new facts will rest almost entirely with those who follow.

To begin with, this discussion will open under quite different circumstances to what it would have done had it been held three, or even two, years ago, for it is now generally accepted that the spirochæta pallida discovered by Schaudinn and Hoffmann in 1905 is the true cause of the disease, and that mercury, formerly given empirically, is a direct antidote by causing destruction of the parasite.

The Name.—This leads me to say a word or two on the three terms applied to this form of the disease—(1) congenital; (2) hereditary; (3) inherited. Of these three I greatly prefer the third. *Congenital*, besides being objectionable in form and suggestion, is not universally true; *hereditary* suggests something that may be passed on indefinitely, of which there is no proof; whilst *inherited* implies only something derived from the parents which is detachable, like a fortune or misfortune, and this more correctly expresses the passing on of the spirochæte to the offspring.

(a) The Opening Address to a discussion before the Society for the Study of Disease in Children, November 13th, 1907.

The Micro-Organism.—The cause of syphilis, whether inherited or acquired, is the presence in the blood and tissues of the same organism, which can be demonstrated in the various secondary lesions, in the blood, and in the internal organs.

The spirochæta pallida is a protozoon of spiral form from 4 to 20 μ in length (about half to three times the diameter of a blood corpuscle), and ¼ μ in diameter, with a flagellum at either extremity. It is very motile, and its motility is of three kinds, a lashing, corkscrew, and a to-and-fro movement. It stains pale pink with Giemsa's fluid, whilst the coarser, highly refracting spirochæta refringens with which it is often associated, stains dark purple.

The Mode of Transmission.—The discovery of the cause of the disease necessitates the re-arrangement of our former views as to its transmission. To those who remember the revolution in thought caused by the discovery of the tubercle bacillus—how that the long-taught diathesis gradually receded into the background and the danger of contagion by inter-communication in houses and families grew into importance—will be prepared for some change of idea in reference to syphilis.

To my mind inheritance from the father alone is now put entirely out of court, and it follows that infection of a mother by her syphilitic fœtus can never occur. For how is it possible that a spirochæte which is highly motile, and whose length averages rather more than the diameter of a blood corpuscle, can penetrate an ovum 200th of an inch in diameter and multiply without destroying it? I lay it down as an axiom, to be demolished, if you will, by discussion, *that inheritance is invariably through the syphilised mother.*

This is supported by Colles's law, that a syphilitic infant cannot cause a chancre on the nipple of its mother when suckling.

It would seem that, when virulent, the spirochætes penetrate the chorion or placenta and occasion miscarriages, macerated fœtuses, or premature births: but when the virus is attenuated by time or treatment the placenta forms a complete protection to the developing fœtus, and it is the separation of the placenta at birth which allows the infection to take place through the umbilical vein. Hence the regularity of the secondary exanthematous stage from a fortnight to three months after birth. In these cases *the separation of the placenta is the first stage, and corresponds to the chancre of acquired syphilis.*

Colles's Law.—I alluded to Colles's law (which was first stated in 1837) in support of the argument that the woman was always first syphilised before the embryo or infant. The law is that a woman giving birth to a syphilitic infant cannot be inoculated with syphilis by the infant when she is suckling it—in other words, though the mother may have shown no definite signs of syphilis, she is immune; whereas the syphilitic infant put to the breast of a healthy woman may inoculate her nipple and convey syphilis to her.

Hitherto, Colles's law has been used as an argument in support of the view that the mother may get a mild form of syphilis from her syphilitic fœtus, whose syphilis is supposed to be derived entirely from the father. But the law of immunity will remain equally true if it be supposed that the mother is first inoculated by the father, a large dose of the protozoon causing an obvious eruptive syphilis, and a small dose a syphilis which misses the eruptive stage.

Syphilis in a man is generally admitted to be capable of transmission to a succeeding generation for a much shorter time than syphilis in a woman, and this supports the view I have stated—viz., that for transmission it is necessary that the woman be first infected.

Transmission by Milk.—The question whether the milk of a syphilitic female may infect a healthy infant at the breast has been discussed for two and a half centuries, since Ambroise Paré, in the seventeenth century, quaintly observed:—"Infants suckled by syphilitic nurses are infected by them, seeing that the milk is nothing but whitened blood, which being infected by the virus, the child fed with it imbibes the same qualities." Hunter, founding his argument on ineffectual attempts to inoculate the blood of a syphilitic person, came to the conclusion that not only the blood, but every secretion derived from it, such as milk, saliva, perspiration, etc., could not convey the disease. But his experiments were inconclusive and his deductions incorrect.

Pellizzari succeeded in inoculating the blood of a syphilitic person, and if Voss's experiment is to be trusted, milk has been directly inoculated also.

A remarkable case bearing on this subject I showed before the Royal Medical and Chirurgical Society in 1881, and it will be re-published in the January number of the *British Journal of Children's Diseases*. A woman, æt. 30, gave birth to a healthy child on December 11th, which she suckled. The following Easter her husband inoculated her with syphilis, but she continued to suckle the child. She consulted me three months later, when suffering from severe secondaries, squamous eruption, sore throat, condyloma, and loss of hair, but the child showed no sign of infection. The mother was then treated with small doses of mercury. She and the child were shown when the latter was 10 months old. He had continued to suckle, and remained plump and in perfect health, though the mother still had patches of circinated squamous syphilide on her arms. During the two years the mother remained under my care for treatment the child showed no sign of inherited syphilis.

The importance of this case rests on the fact that the mother had suckled her child for three months after her infection before any treatment was commenced, so that it cannot be argued that the infant was taking the antidote in the mother's milk with the poison, and so escaped a source of possible inoculation; but it proves that the milk of a syphilitic woman when received into the alimentary tract of an infant need not convey any infection to the child.

Transmission by Semen.—It is obvious, as the greater cannot be included in the less, that a spirochæte cannot be carried in a spermatozoon; but this does not exclude the possibility of the spirochæte being conveyed by the fluid parts of the semen

The early experiments of inoculation by Mireur failed, but if the recent results obtained by Finger on monkeys be correct, the semen of syphilitic men in the secondary stage is inoculable. It seems almost necessary that it should be so to account for the cases of inherited syphilis conveyed after the healing of the chancre. If the presence of the spirochæte can be with certainty demonstrated in the semen of men suffering from recent syphilis, much doubt would disappear; and, in the cases where no chancre could be traced in the woman, the probability of the infection being carried through the uterus, after the disintegration of its lining membrane at any menstrual period, would be apparent.

Transmission to the Third Generation.—Another question much open to discussion is whether syphilis inherited is capable of transmission to the third generation. If the tertiary symptoms, occurring ten or twenty years after inoculation, can be proved to be due to renewed activity of the spirochæte in certain situations, there seems to be a fair possibility of their being carried to a third generation. But the question is beset with difficulties, since you must prove the sexual purity of two persons up to the time of maturity, and these are generally persons in whom a tendency to vice is also hereditary; for it is known that a person the subject of inherited syphilis is not immune from re-inoculation after a certain period.

Hutchinson mentions eight cases that have come under his observations of persons who presented signs of inherited syphilis, and who married, but whose offspring showed no evidence of the disease.

On the other hand Edmond Fournier collected 116 cases, 59 of which he thought were to be relied upon as showing transmission to the third generation, and R. W. Taylor has published others.

Dr. D. M. Hutton brought a case before this Society, which is published in the first volume of our Reports, and is there criticised by Dr. Ashby and others.

My own experience is limited to one case, but it is of unusual importance, as both parents showed most obvious signs of inherited syphilis which were unmistakable. A blind man attended a school for the blind, where he met a blind woman for whom he developed a feeling of affection. They were both blind from interstitial corneo-iritis, and they both presented the typical physiognomy of the inherited disease, notched teeth and scars around the mouth. They married, and at the time the man came under my care, their first child was about two months old. The blind wife was brought up to visit her husband, and, seeing she was marked by the same disease, I sent for the infant, which presented no evidence whatever of syphilis, nor did it develop any symptom of inherited disease during the months I was able to keep it under observation. This case, in which there should have been double inheritance, showed, so long as I was able to watch it, complete immunity.

The Infant Mortality.—There is probably no disease responsible for such an enormous destruction of human life in its earlier stages as that caused by syphilitic parentage. But my experience shows that this mortality is greatest in those families where both parents have suffered from chancre syphilis and obvious secondaries. The severity of the infection and ineffective treatment, or lack of treatment, are the two factors which determine the mortality. I give two illustrations:—

CASE I.—E. S., had been married eleven years, and suffered three months after marriage from rash and sore throat. The first child was stillborn, twelve months after marriage, and was miscarried at the sixth month. The second child lived (the mother being at this time under treatment), but had severe snuffles and rash, is very delicate, and has recurrent sores and eruptions. The third, fourth, fifth, sixth, seventh, eighth, and ninth children were all born at full time, but all died from a few minutes to within two or three months of birth. The tenth child was brought up for treatment suffering severely from snuffles, stomatitis, and coppery shiny eruption. Thus two weak children only were living out of ten.

CASE II.—R. C., three weeks after marriage, suffered from sores on vulva followed by rash and sore throat, for which she had no prolonged treatment, a pale, cachectic-looking woman. The first child, ten months after marriage, was stillborn at the seventh month. The second child was prematurely born at the eighth month, and lived a day. The third child, born at full time, a fortnight later came out in large brown spots, and had snuffles, and was taken to Guy's and treated by blue ointment rubbed in over the abdomen. She still lives, and at the age of eleven shows no notching of incisors or evidence of her inheritance. The fourth child did not come out in an eruption till five weeks old. He died at six weeks. The fifth child, a boy, came out in an eruption at five weeks, and died at seven weeks. The sixth child was stillborn. The seventh child, prematurely born at the eighth month with an eruption upon her, survived a day. The eighth child, a girl, had a rash soon after birth, and died on the eighth day. The ninth, also a girl, was born healthy, but an eruption came out at the third week. She was treated, but died at eleven weeks. The tenth, a fine boy at birth, came out in an eruption three weeks after birth, and was brought up for treatment. He was suffering from symmetrical squamous syphilide of legs, feet, arms and ears, little on body, ulceration of mouth and buttocks, and severe snuffles. Again two living out of ten.

The Secondary Stage.—The trite definition that "syphilis is a fever diluted by time," given by the late Dr. Moxon, is applicable to the inherited as well as to the acquired disease.

I argued that the primary stage is the separation of the placenta and the infection of the infant through the umbilical vein. The secondary or exanthematous stage commences from the second week to as late as the third month. It is characterised by eruptions which may vary from slight brown macular syphilides to pompholyx, by snuffles, stomatitis, condyloma, wrinkled skin and wasting, enlargement of the spleen and liver. Then follow certain changes in the bones, in severe cases perhaps epiphysitis, giving rise to pseudo-paralysis, Parrot's nodes causing natiform skull and square forehead, cranio-tabes and bent bones.

It cannot be too strongly insisted on that the moist eruptions and ulcerations about the mouth and anus, as well as the vesicular skin affections, are charged with the spirochætes, and highly contagious.

From the second to the sixth year there is commonly a rest in the symptoms that are regarded as characteristic, but the tibiæ may become thickened from periostitis, or a joint may become swollen and painful, and resolve under mercurial treatment.

But now the characteristic physiognomy has been gradually formed, the flattened nose, the square forehead, the radiating lines from the mouth, the stunted figure and pallid face; and then, during the second dentition, we look for the three signs pointed out by our great observer, Jonathan Hutchinson, the notched incisor teeth, insterstitial corneitis, and syphilitic deafness. Associated with such signs, or occasionally independent of them, gummatous destruction of the soft or hard palate may occur, and ulcerations of the skin and cellular tissue. Destruction of the nasal bones, caries of the forehead and skull, of the long bones and dactylitis, may take place as the result of the inherited disease.

Moon's Molars.—The teeth Mr. J. Hutchinson described as so characteristic of the disease are the notched and narrowed incisors, especially the central incisors of the upper jaw. This defect is brought about by arrest in development of the central columella, of which each incisor has three. But I wish to draw special attention to the characteristic change brought about by the disease in the first molars described by the late Mr. Henry Moon many years ago, since this change has recently been re-discovered both in America and on the Continent. The diagram which I show is taken from the fourth edition of *Bryant's Surgery*, published in 1884, wherein the article on teeth is written by Mr. Moon. He figures and describes the syphilitic first molar as "reduced in size and *dome*-shaped, through the dwarfing of the central tubercle of each cusp." He also contrasts these teeth with mercurial teeth and syphilitic-mercurial teeth. The change in the molar is of some clinical importance, since occasionally it is characteristic when the incisors are normal.

Eyes and Ears.—The eyes may become affected at an early stage by a choroido-retinitis, which may leave permanent changes easily recognised by ophthalmoscopic examination; and iritis, though rare, may occur during the eruptive stage. Interstitial keratitis is most frequent between the ages of six and sixteen, but may occur much later, and rarely earlier. It is highly characteristic of the inherited disease.

Like the eyes, the ears are attacked by different affections in the early and late stages. During the eruptive stage, otitis media may commence as an extension from the inflammation of the naso-pharynx, whilst during the second dentition a progressive deafness of labyrinthine origin may cause complete loss of hearing. Specialists in these departments will, I hope, give us some new facts relative to the syphilitic manifestations in the eyes and ears.

Inherited Syphilis Attacking the Viscera.—Much work has been done in demonstrating the disease in the various viscera, not one of which appears to be exempt, and there is probably a large field still open here for further investigation. Enlarged spleen and liver, associated with rickets, may be proved almost invariably to be of syphilitic origin.

The disease attacks the various organs in two forms, as a small cell infiltration usually following the course of the vessels, which in its development and decline may lead to fibrosis and consequent atrophy, and as a gummatous tumour which is less common.

When the inherited disease attacks both testicles or both ovaries at an early age, and brings about their fibrosis and atrophy, a condition known as *infantilism* is produced at a period when the sexual characteristics should be pronounced.

The physicians present will, I hope, give us much new information on inherited syphilis of the viscera.

The Nervous System.—Much difference of opinion exists as to the frequency of nervous disease dependent on inherited syphilis. Whilst some are inclined to attribute every conceivable weakness, paralysis, or mental defect to this disease, others regard the nervous lesions dependent on it as infrequent. A certain proportion of epileptics, deaf mutes, and idiots, but not a large percentage, show signs of inherited syphilis. On the other hand, syphilitic endarteritis of cerebral vessels, gummata on nerves, and sclerosis of brain and spinal cord have been observed by competent observers.

One of the most interesting observations of late years is that some cases of hydrocephalus are dependent on inherited syphilis, and are curable by mercury.

The Need of Criticism in Diagnosis.—In conclusion, I wish to insist on the importance of weighing carefully all the evidence before determining that a particular affection is due to inherited syphilis. Every deformity from dislocated hip to cleft palate, all defects such as hernia, infantile paralysis of various kinds, and even nævi, have been described by various writers as dependent on inherited syphilis, and as if better to cover the anomalies, the term "parasyphilis" has been invented to add to the confusion. I need scarcely waste time in combating such crude generalisations as that "all rickets takes origin in syphilis," when any puppy taken from a litter and deprived of proper food and exercise will certainly develop this disease.

Equally crude statements have been made as to other diseases. We do not deny that persons whose constitutions have been weakened by disease are liable to produce degenerates in succeeding generations; but in future the most certain test of the disease being syphilis will be the presence of the spirochæta pallida in the part affected. This organism has an extraordinary persistency producing local symptoms after lengthened periods, but happily we have in mercury and the iodides drugs which control its development and bring about its destruction.

Metchnikoff has recently shown that some hours after direct inoculation the application of a calomel ointment to the sore is sufficient to kill the organism and prevent the occurrence of secondary symptoms.

Gentlemen, I have now finished my brief sketch of this interesting disease as it attacks the second generation. It is the merest outline, that you may fill in the substance. I ask for new facts and new observations, for now that the cause of the disease is definitely known, we have a fresh incentive for further investigation. There are many diseases still confused under a common name—just as gonorrhœa and syphilis, typhus and typhoid fever, were confused generations ago—that time will unravel. But as we gain more exact, more precise, and more definite knowledge of any one disease, we shall be the better equipped for appreciating the symptoms and distinguishing the effects produced by others.

EYE-STRAIN. (a)

By T. PERCY C. KIRKPATRICK, M.D., F.R.C.P.I., M.R.I.A.,

Visiting Physician to Dr. Steeven's Hospital.

With the appearance in 1864 of the great work of Donders "On the Anomalies of Accommodation and Refraction of the Eye," scientific ophthalmology may be said to have had its birth. In the *Philosophical Transactions* of 1793, Dr. Thomas Young had described the condition of astigmatism, but his work does not appear to have had much effect on the practice of ophthalmologists till the whole subject of abnormal refraction was placed on a sure and scientific basis by the work of Donders. The evil effects which follow from the fatigue due to excessive action of the ocular muscles in cases of abnormal refraction of the eye were clearly pointed out by Donders, so far as they affected vision, but it was not till some years later—1874—that Weir-Mitchell, of Philadelphia, suggested that the evil effects of this ocular fatigue, or eye-strain, were of much wider distribution. Since the appearance of Weir-Mitchell's papers, many writers have treated of this, and recently the subject has been brought prominently before the profession in a series of publications by Dr. George M. Gould, under the title of "Biographic Clinics." In spite of the amount of work which has already been done, it is quite evident that physicians are not yet satisfied as to the position which eye-strain is to ultimately assume among the recognised causes of disease.

During the past few years I have devoted considerable attention to this question, and I bring the results of my observations before the Academy, not because I believe they contain anything new, but in the hope that from the criticism of my fellow-members my deductions may be corrected or amplified.

There is one great group of diseases which does not appear to me to have taken an adequate share in the great advance which has characterised the history of medicine, both preventive and curative, in the latter half of the nineteenth century. I refer to those diseases known vaguely under the generic title of the "functional neuroses."

Much has been done, no doubt, by the gynæcologist, the rhinologist, the aural surgeon, and the dentist for the treatment of conditions formerly classified in this group; but, in spite of this, the number of persons affected appears to become greater year by year. It has been customary to give as an explanation of this the stress of modern civilisation, and the survival of the unfit, which has followed the great progress of preventive medicine. Both factors have probably contributed to the result, but so far from allowing this to paralyse our efforts to prevent and to relieve the suffering caused by the functional neuroses, it should, I maintain, stimulate us to greater efforts to complete the triumph of medicine by making efficient and happy citizens of those whom the success of preventive medicine has spared to the State. My observations on a number of patients have led me to believe that in the recognition and removal of eye-strain we have a very valuable means of reducing considerably the number of persons who suffer and have their efficiency greatly impaired by various disabilities at present known as functional. It is not possible for me to go into details of all the conditions and disabilities which may result from eye-strain; I shall merely, by the record of some few cases, endeavour to establish the general principle that it is the duty of the physician to look for and correct any abnormality of the eyes in every case of disease which does not readily and completely yield to treatment by other means. That this principle is not recognised at present, or, if recognised, not always acted upon, I have had ample evidence, although it does not appear to be in the least unreasonable. There are, I believe, few physicians who would not consider it a grave neglect to omit examination, and, if necessary, treatment of the teeth in such cases. Although many persons have diseased and unhealthy teeth without appearing to suffer from them, still the importance of removing that source of irritation and infection in every patient is fully recognised. Though this be so, it has been seriously urged against the adoption of the principle I have advocated that many persons with considerable refraction errors do not suffer in the least from the condition, and in others who do suffer the correction of the error brings no relief. To submit a patient to such a serious operation as the removal of the Gasserian ganglion for trigeminal neuralgia without first ascertaining that there is no ocular defect, or the result of its correction if present, appears to me to be quite as bad as to amputate his leg for a tumour without satisfying oneself that the condition was not due to syphilis rather than cancer. Before proceeding to deal in detail with the cases I should like to insist on the necessity of making the examination of the eyes thorough, and correcting as far as possible any abnormality that may be found to be present. This should be conscientiously done before any opinion is expressed as to the possibility or not of the abnormality present causing the symptoms. I know it is the practice of some ophthalmologists to neglect minor refractive errors provided the patient's vision is fairly good, and to assert that the error is so small that it cannot be looked on as a cause of severe symptoms. Such a position is not warranted, and every source of eye-strain should be removed before one asserts that the symptoms complained of are not due to it. Some writers have found that slight errors are more potent in the causation of symptoms than those of a more aggravated degree. This is quite intelligible when we remember that slight errors will probably interfere only to a very slight degree with vision, and consequently the eyes may be subjected to prolonged strain without the patient being aware of the fact. It is remarkable how often such patients will resent the suggestion that their eyes are at fault, asserting that they can see perfectly well, although on trial they at once feel the benefit of suitable glasses. This has been my experience with several patients.

(a) A paper read before the Medical Section of the Royal Academy of Medicine in Ireland, December 6th, 1907.

The first condition of which I wish to speak is the group of symptoms known as migraine or hemicrania. Migraine forms such a well-defined and easily recognised clinical entity and is so common that it is unnecessary for me even to enumerate its symptoms. The time at my disposal would be quite insufficient were I to endeavour to enumerate the various hypotheses as to its causation and the methods which have been recommended for its cure. Suffice it is to say that none of these hypotheses satisfactorily explain the condition; and most of us will agree with Osler's remark, "that in a very large proportion of the cases the headaches recur in spite of all we can do." It has long been recognised that various functional disturbances of vision form a prominent symptom in migraine, and it has been recently demonstrated that a large number of patients thus affected have some abnormality of refraction or muscle balance of the eyes. It has also been shown that many cases of migraine are immediately and permanently cured by the correction of such abnormality. I am not aware that anyone has yet published statistical tables of a large series of cases in order to enable us to estimate whether in all or what percentage of patients with migraine ocular abnormalities have been found, and the results that have followed the correction of such abnormalities; but a sufficient number of cases have now been published, where some abnormality has been found and the patient cured by its correction, to make it clearly our duty to look for such abnormality in every case of migraine. The compilation of such a table would, I believe, be an important and useful contribution to the work of our Dublin School of Medicine.

The following case well illustrates the connection between eye-strain and migraine: A young man, aged about 24 years, came to me complaining of well-marked migraine. He was a clerk by occupation; a teetotaller and non-smoker. On physical examination he appeared to be perfectly sound, and there was no family history of nervous disease. His eyesight was quite good, and between his migrainous attacks he was quite healthy. He stated that he had been subject to attacks of severe sick headache since childhood. These attacks came on quite suddenly, usually beginning with the feeling that the objects about him were moving from side to side. These ocular symptoms were soon followed by violent headache, and after some time he vomited; he was usually quite well again in from three to five hours after the attack began. These attacks came at irregular intervals, sometimes two or three in a week, and sometimes there would be an interval between them of two months. He was unable to account for the attacks by anything in his mode of life or diet, and often they came on when he was feeling particularly fit. He had been treated by many drugs prescribed by different physicians, but from none had he received any permanent benefit. I recommended him to have his eyes examined, and he consulted an oculist in town, who subsequently told me that the patient had 0.25 diopters of myopic astigmatism, and although he considered the error to be too small to cause the symptoms, he had ordered correcting glasses. My patient got the glasses and used them regularly, but in about a month came back to say that so far from being improved, the migraine attacks were more frequent than they had ever been before. I advised him to return to his oculist and ask if there was any change to be made in the glasses. The oculist reported that the glasses were perfectly correct, advised a further trial of them, and, though he did not say so, suggested that the result was just what he had expected. My patient found that the glasses appeared to make his migraine worse the longer he persisted in using them, and eventually decided to get further advice. The next oculist he consulted recognised the presence of faulty muscle balance, which he said was probably of more significance than the astigmatism, and ordered glasses for its correction. For a year after using these glasses my patient was quite free from all migraine—a longer period of freedom than he had known since the attacks first started. He then had one slight attack, not accompanied with vomiting, after which he again had some slight change in the glasses, and since then has been quite free from all signs of the disease. It would not, of course, be right to draw any definite conclusions as to the causation of migraine, but this at all events is clear, that in his case the correction of the eye-strain was the only method of treatment attended with any success. The case also shows the great importance of a careful and thorough examination of the eyes before we can conclude that they are not concerned in the production of the symptoms complained of. I now believe that the oculist the patient first consulted was right in so far that the astigmatism had little if anything to say to the migraine, but he missed what in my opinion was the essential feature of the case, the faulty muscle balance; and had not the patient sought further advice he would in all probability be still suffering from his periodic attacks of migraine.

I do not wish to be understood as maintaining that migraine is always the result of eye-strain—the information at my disposal does not warrant me in doing so—but I do maintain that the connection has now been so frequently established that it is one of our first duties in every case of the disease to see that all sources of eye-strain have been removed, and not to be satisfied with any incomplete examination of the eyes or protestations of the patients as to the excellence of their vision.

The connection between eye-strain and headaches, the so-called neuralgia, is now so well established that it appears almost unnecessary to dwell upon it here. I have found, however, that in spite of this knowledge, many physicians when dealing with cases of headache do not insist on an examination of the eyes unless there is obvious defect in vision, and further, that many oculists do not consider it necessary to correct slight refractive errors provided the vision is good. There are, of course, many patients who will not bear complete correction of refractive errors, at all events at the start, but there are others who do not resent the glasses though they do not find that their vision is improved by them, and many such patients are left uncorrected.

As an example of this I give you the history of the following case:—A young woman of about 22 years of age consulted me at the out-patient department of Steeven's Hospital some seven years ago, complaining of severe recurrent headaches. I examined her carefully and made a note in the register, "complaining of headaches, but I can find nothing else wrong with her." I treated this patient with purgatives and tonics for some time, but with no evident improvement, and the patient disappeared, as I suppose to seek treatment elsewhere. Some three months ago she came again to my dispensary and told me she had been in America in the interval; she was now complaining of some slight dyspepsia. On looking her name up in the book and seeing my previous note, I at once asked about the headaches, and she replied that while in America she had sought advice for her headaches, and had been ordered glasses, and since wearing them the headaches had completely disappeared. I greatly fear that there are only too many other patients whom I have left to suffer in a similar way from not having recognised the necessity of seeking the aid of the oculist. The following instructive case also illustrates the benefit of treating eye-strain and the difficulty one sometimes encounters. Some eighteen months ago I was called in a hurry to see a gentleman in town by his partner in business, who informed me that he believed the patient was going off his head, and had made some remarks which suggested suicide. As the usual medical attendant was out of town I was asked to see the patient with a view to getting him into hospital. I found the patient in a very restless and excited state, complaining of severe headache, and saying that at times he felt quite unable to control his actions. I had him at once removed to a private hospital, ordered complete rest and a full dose of bromides. During the next two or three days his condition improved greatly, and he expressed himself quite well except for some headache, which, however, he said he nearly always had. On making inquiries as to the cause of this headache he informed me that he had suffered from headache more or less continuously for the past fifteen years—at times it was better and at times it was worse—but very seldom was he quite free from it. He further told me that he had consulted many physicians, but got no relief in spite of the varied treatment prescribed. One physician, after careful physical examination, told him that he could find nothing wrong with him, and so it was useless to recommend medicine. The patient himself attributed the headache to excessive lawn tennis playing, at which game he had attained considerable proficiency some 15 or 20 years before. I suggested that probably his eyes were at fault, and that the glasses which he was wearing did not suit him. He indignantly repudiated the suggestion, and proceeded to demonstrate to me that his vision was exceedingly acute. I told him that it was not a matter of vision, and asked him to consult his oculist. On my pressing this matter again the next day he said to me, "As a personal favour, doctor, I must ask you not to mention this matter any more, for I know you are wrong, and I do not wish to fall out with you." The patient passed from under my care on the return of his usual medical attendant to town, and I informed this gentleman of my opinion, and asked him to use his influence with the patient to have his eyes examined. I heard nothing more from the patient for about six weeks, when one day he stopped me in the street and said he wished to thank me for my advice, for he had been to his oculist, had his glasses changed, and since that had experienced such freedom from his headaches and general improvement in his health as he had not known for 15 years. The sequence of events is so striking that one is strongly tempted to assume a causal relationship. This case does not, however, stand alone, for I have had several others in which the use of suitable correcting glasses has been followed by complete relief of more or less persistent headache that for years had resisted other forms of treatment. I have also, of course, had cases in which I suspected the eyes to be at fault, but on examination they were found to be perfectly normal. Such cases do not, and I think should not, in any way prevent the adoption of the general principle that I advocated to have every such patient's eyes carefully examined.

Some recent writers have attributed all sorts of chronic ill health to the presence of eye-strain, but as I have not myself had experience of such cases I do not purpose to consider them to-night. If one may express an opinion on *à priori* grounds, I should be inclined to doubt the causal connection in many such cases, but I am quite prepared to admit the presence of eye-strain may be an important factor in such cases, the origin of which was due to some totally different cause. It is quite possible, indeed I might say even probable, that the eye-strain itself may be the result of the condition of ill-health which has interfered with the nutrition and function of the ocular muscles, and when once established this eye-strain may help in maintaining that condition to which it was itself due. We have ample evidence of the importance of such vicious circles in many cases of disease, and it would seem illogical to exclude it here.

I fear I have no very plausible hypothesis to offer in explanation of the contention which I have put forward. It seems to me difficult to accept the explanation suggested by Donders that the excessive muscular action produces waste products the accumulation of which acts as a poison on the nerve cells and fibres. The very small bulk of the muscle involved appears to me to make such an explanation untenable.

Excessive stimulation of the muscles or the nerve centres, one would think, would be followed by loss of function of these muscles or nerve cells with consequent relief of the eye-strain rather than by symptoms in other and distant parts. At most one would imagine that a condition analogous to what we find in writer's cramp would result. While however we are compelled to speculate on the explanation of such conditions, we should remember how scanty our knowledge is of the intimate relations of the central nervous system, either anatomically or physiologically considered.

I have tried by the relation of these few cases which have come under my own observation to establish the importance of eye-strain as a factor in the production of disease, to impress on my hearers the importance of the removal of this eye-strain as a method of treatment, and to solicit their criticism for my own guidance. That I have found the adoption of these principles of advantage to myself, and I hope to my patients, must be an apology for detaining the Academy so long. I must tender my very best thanks to my friend, Dr. Mooney, for his kindness in devoting so much care and attention to the laborious investigation of the many refraction cases which I have sent him at the Royal Victoria Eye and Ear Hospital.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Three Cases of Fæcal Fistula.—Mr. T. P. Legg operated for fæcal fistula on three patients:—(1) The first was a young woman, æt. about 23, who some years before had had some operation performed in her right groin; since that time had had a fæcal fistula which constantly discharged large quantities of thin, watery, intestinal contents, with an acid reaction. She was in a deplorable state, her right thigh being excoriated and in an eczematous condition nearly as low as the knee. The lower part of the abdomen on both sides was in a similar condition. She was very much emaciated, and had practically to spend her whole time in bed, which was the only place in which the fistula leaked very slightly. The opening was situated in the upper and inner part of Scarpa's triangle, just below the middle of Poupart's ligament; it admitted a No. 8 bougie, which passed upwards and backwards. For some days she was kept in bed, and various diets were tried to diminish the amount of leakage, and to get the skin into a better condition by the use of various applications. At the operation a bougie was passed through the fistula, the opening of which was then closed by suturing over the end of the bougie, and a small collodion dressing was fixed over the sutures. The abdomen was next opened just through the middle of the right rectus; very few adhesions were found, and on passing the hand downwards to the lower part of the iliac fossa it was quite easy to feel the bougie passing into the ileum not far from its termination. The rest of the peritoneal cavity was packed off, and this adherent piece of ileum was separated from the bougie and drawn up on to the surface of the abdomen; there was no attempt at the formation of a spur, the hole in the bowel being about a third of an inch or more in diameter, and situated towards the anti-mesenteric border. It was closed by invagination, two rows of sutures being used; some narrowing of the lumen resulted. The abdomen was then closed completely, a small drainage tube being placed along the track of the fistula. (2) The second was that of a man, æt. 37, who was admitted with a large tumour of the right kidney and pus in the urine. The kidney tumour was removed, and in doing so a portion of the intestine must have been bruised during the separation of the adhesions, which were very abundant. Four or five days after the operation a slight fæcal discharge was noticed on the dressing, and a few days later it was quite easy to see in the lower part of the incision (which had been left open in order to pack it) a small opening into the bowel. The amount of intestinal contents which escaped varied, but caused considerable excoriation of the skin around. The reaction was acid, and flakes of milk and bile were easily recognisable in the discharge. As the fistula showed no signs of healing, an attempt was made to close the opening by separating the intestine from the incision and invaginating it by two rows of sutures ; for a time the discharge ceased, but again the fistula recurred, and another attempt was made to close it in the same manner ; this was again unsuccessful. As the patient was losing ground, and the amount of discharge was abundant, it was decided to more thoroughly explore the condition of the bowel by opening up the original wound. After separating the adhesions, the affected piece of intestine, which was the upper part of the jejunum, was found to have a well-marked spur, so that the proximal portion was almost entirely shut off from the lower part, and all the contents of the former portion of the bowel were unable to pass into the lower ; hence the failure of preceding operations. About 4 inches of intestine, with the spur, were excised, and the two ends united together by two rows of sutures. Most of the wound was sewn up, a small piece of gauze being left in to stop some oozing from the raw surface left by separating adhesions. (3) The third was that of an older man, nearly 50, who had been originally operated on for a large abscess in the upper part of the right groin. At this operation the abscess was found to originate in the right iliac fossa, and, as a sinus was left, the fossa was explored through an incision above and parallel to Poupart's ligament. The source of the abscess was apparently from the cæcum, which was much thickened. It was thought inadvisable to do more at this time, so the wound was packed and allowed to heal. During this process a fæcal fistula formed, with two openings, one just above Poupart's ligament, and the other at the upper and outer part of the thigh ; from the latter there appeared to have been more discharge than from the former ; the amount varied, sometimes it was absent, but the quantity was sufficient to prevent the patient from following any employment. He had also steadily lost flesh. In the right iliac fossa there was a definite amount of induration, and with a view of first, if possible, finding out the exact source of the disease and removing it, and, secondly, to perform some operation for the cure of the fistula, it was decided to open the abdomen. When this had been done, the cæcum and ascending colon were found to be very closely adherent to the parietes, and, except for being thickened uniformly, not otherwise obviously diseased, so it was decided not to attempt their removal. The fistulæ apparently opened on the posterior aspect of the bowel ; at any rate, they were not seen on the inner lateral aspect, which was clearly exposed. The termination of the ileum was free from adhesions ; it was divided about 6 inches from the ileo-cæcal valve, and both ends completely closed by two rows of continuous sutures. The proximal piece was then applied to the transverse colon, which was situated quite low in the abdomen, and a lateral anastomosis was made between these two pieces of intestine not far from the hepatic flexure. The abdomen was then completely closed, without any drainage. The fistulous tracts were scraped and packed, and a piece of gauze inserted. Mr. Legg, in his remarks, said that these three cases illustrated three different methods of treatment of fæcal fistula. The first case was the simplest method, and can generally be adopted when there is no spur, and the opening can be found ; sometimes it was easy to do this, especially when there were few adhesions, and those not dense, or it may be impossible, as in the third of these cases, or inadvisable, to attempt their separation. He thought that placing a probe or bougie along the fistula was a valuable guide to the situation of the track and of the opening in the bowel, as in the first case. In the third case not any assistance was really gained by having a bougie placed in the fistula, for it could not be felt inside the abdominal cavity. The second case illustrated the only way of curing a fæcal fistula when there is a spur, and in excising the intestine enough must be removed to get healthy bowel above and below to join together. In many of these cases the adhesions may be so close that a very careful dissection is necessary. The third patient illustrated the method of curing the fistula by "exclusion" of a portion of the bowel. In this particular operation the termination of the ileum, the cæcum, and a portion of the colon were excluded in part from the direct track of the intestinal contents. As the transverse colon was not divided, but only united to the ileum, any secretion from its mucous membrane, or any intestinal contents which happened to be in it, would be passed on by the natural peristaltic wave into the colon beyond the anastomosis. In this operation of "exclusion" of a portion of the intestine, the excluded portion must always have left some means of escape for its contents until such time as it ceases to secrete and shrivels, if it ever completely does so. Now, as the ileum was anastomosed to the transverse colon by a large opening, the only thing left to keep open the fistulæ was the secretion of the mucous membrane of the intestine with which they were connected, and when a piece of intestine is put out of use, its secretion diminishes to a very small amount. Therefore, these fistulæ would probably close, and at most might occasionally reopen if the intestinal secretion accumulated to any great extent. Incidentally these three cases illustrated the different effects of the intestinal contents on the skin. In the first and second cases there was widespread excoriation, due to the secretion and contents of the small bowel. The third patient in whom the contents of the large intestine escaped showed very slight alteration in the skin. The first and second patients also emaciated much more rapidly and to a greater extent than the third patient, the emaciation being most quickly evident in the second case, in whom the fistula was high up in the jejunum. Mr. Legg also pointed out that the contents of the small intestine being fluid, the narrowing which was present in the calibre of the bowel, as the result of the operation in the first case, was not likely to lead to symptoms of stricture, especially as the scar was placed in the long axis of the intestine. The result of the operation performed in each case was quite successful, and it was interesting to notice how rapidly the skin recovered in the first and second cases.

TRANSACTIONS OF SOCIETIES.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

CLINICAL MEETING.

CLINICAL MEETING, HELD DECEMBER 18TH, 1907.

The President, Dr. JAMES RITCHIE, in the Chair.

DR. ALEXANDER BRUCE showed—(1) a case of syringomyelia of the rare type associated with contraction of the muscles of the shoulders, elbow, wrist and fingers. The patient also had dissociated anæsthesia of the arm. (2) A patient with well-marked hemiatrophy of the tongue and lateral nystagmus. The girl was also subject to attacks of giddiness, in which she had a sensation of objects rotating to the left. There was also a history of numbness in the left arm. The nature of the case was obscure ; there was probably a lesion in the neighbourhood of the hypoglossal nucleus, extending forwards to implicate the centres for the external recti. (3) A case of neuritis of the median nerve, following cellulitis consequent on an injury to the palm of the hand. There was marked hyperalgesia, and the cutaneous distribution of the fibres of the median nerve was very distinctly mapped out by the disturbance of sensation. (4) A case of amyotrophic lateral sclerosis. (5) An aneurism of the internal carotid artery ruptured into the cavernous sinus, producing well-marked proptosis of the left eye, and giving rise to a loud buzzing murmur audible on auscultation over any part of the cranium, but loudest at the point where the tip of the sphenoid and temporal bone unite. (6) A patient who showed marked emotional disturbance, tremor of the right arm, narrowing of the right palpebral fissure and increased flow of tears from that eye. There was also unilateral sweating, limited to the right side. The case was regarded as of functional nature.

Professor **Chiene**, C.B., showed:—(1) A case of congenital wryneck. He had never felt satisfied with the operations performed for this deformity, and in the case in question had devised a new one, which consisted in the reflection of a flap of skin over the mastoid process, the dissection off the bone of the periosteum and attachment of the sterno-mastoid, and the suture of the upper part of the periosteum detached to the lower part of the mastoid process. The amount of periosteum detached was regulated by the amount of shortening of the muscle—in this case 2 inches. The result had been good; the scar was not in the neck, as when the lower end of the muscle was divided. (2) A case of loose body in the elbow-joint, following injury. He had operated as follows, the object being to preserve the integrity of the lateral ligaments:—A horseshoe-shaped flap was turned down over the elbow, and the triceps was split by a vertical incision. He was surprised at the free access to the joint which this gave, and suggested that similar incisions might be used for excision. There was no scar over the olecranon, hence it would be possible to begin passive movements very early. Mr. Chiene also demonstrated —(1) an instrument devised for measuring the length of the lower extremities; (2) a shield to wear over the mouth and nose when operating; (3) an improved support for flat foot, embodying the principle of supporting the transverse as well as the longitudinal plantar arch.

Mr. F. M. **Caird** showed a series of ten patients in whom the operation of pyloro-gastrectomy for cancer of the pylorus had been performed. The earliest case dated back to 1899, another to 1900; the rest were of more recent date. In all the history was much the same—vomiting, absence of free HCl, and movable pyloric tumour. Although the growth was often felt to be movable, there were usually troublesome adhesions, particularly to the pancreas. The operation generally performed was to suture the divided ends of stomach and duodenum, and then to perform a posterior gastro-jejunostomy. The operations were troublesome, and took from two to three hours for their completion. (2) A case of acute pancreatitis, treated by drainage. (3) A case of idiopathic dilatation of the colon. The patient was admitted with a greatly distended abdomen, showing conspicuous ladder patterns, and signs of chronic obstruction. An artificial anus was made, and subsequently the loop of bowel which had been drawn into the wound was resected, the ends of the colon being united by end-to-end anastomosis. The difficulty with the regular action of the bowels had been overcome, and there were no more ladder patterns, but the abdomen was still rather tumid.

Dr. R. W. **Philip** showed a series of patients illustrative of the cutaneous and ophthalmic reaction of tuberculin. The former was introduced by von Pirquet, of Vienna, and consisted in the inoculation into the skin of a small quantity of tuberculin. In tuberculous subjects a cutaneous reaction consisting of redness, papulation, and occasionally vesiculation, ensued. The ophthalmo-reaction had been introduced by Prof. Calmette, of Lille, and was tested by instilling into the conjunctival sac one drop of ½ to 1 per cent. solution of dried tuberculin prepared by precipitation with absolute alcohol. Tuberculous subjects showed within three to six hours injection of the caruncle, slight conjunctivitis, and occasionally a muco-purulent discharge. It was noted that sometimes patients with advanced tuberculous symptoms failed to react, just as they sometimes failed to react to injections of tuberculin.

Mr. **Alexis Thomson** showed:—(1) A patient, æt. 69, after a radical operation for carcinoma of the cæcum, performed in two stages. He demonstrated a new pattern of enterotribe, by which it was possible to compress the colon into a pulpy ribbon; then the softened part was invaginated, and the end closed as easily as after removal of the appendix. (2) A patient, æt. 53, operated on for acute intussusception confined to the small intestine, which, being irreducible, the entire segment of gut involved, including the sheath, had to be resected. Intussusception limited to the small intestine was rare. After removal of the gut he had slit it up in the expectation of finding a tumour which would have caused invagination to occur, but none was present. The patient had complained a great deal of abdominal pain and irregular peristalsis since the operation, and his future could not be looked upon without anxiety being felt lest repetition of the intussusception should occur. (3) A patient, æt. 29, who had sustained a gunshot injury of the upper arm six months before he came under observation, with smashing of the humerus and tearing of the musculo-spiral nerve. An operation was performed for ununited fracture of the humerus, when it was found that the extent of the destruction of the nerve rendered suture impossible. The distal end was therefore inserted into the median nerve above the elbow, and there had been considerable return of power. He proposed now to complete the bridge by grafting the proximal end of the divided musculo-spiral into the trunk of the median nerve.

Mr. **Hodson** showed patients:—(1) After operation for renal hydatid. (2) A case of Dupuytren's contraction after treatment by fibrolysin.

Mr. E. **Scott Carmichael** showed—(1) Boy, æt. 10, after acute suppurative cholangitis and cholecystitis following generalised streptococcal peritonitis. (2) Girl, æt. 6, after severe compound fracture of the skull and hernia-cerebri. (3) Girl, æt. 3, after resection of the cæcum and ascending colon for tuberculous stricture two years ago. (4) Boy with chronic arthritis of the wrist-joint of doubtful diagnosis.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Medicine.

Meeting held Friday, Dec. 6th, 1907.

Dr. A. R. Parsons in the Chair.

DIPHTHERITIC FEVER.

Sir **John Moore** gave details respecting a remarkable outbreak of sore throat which had come under his observation in a large girls' school in Dublin during the autumn of 1906. Bacteriological examination proved the outbreak to be due to an infection with a form of the Klebs-Löffler bacillus diphtheriæ The resulting illness failed to present the typical features of classical diphtheria—it might be described as "Diphtheroid," and he had ventured to call it "Diphtheritic Fever." From October 2nd, 1906, to November 11th, following, 18 out of a total of 43 girls in the school were attacked—that is, 41.9 per cent. There were five distinct outbreaks. In the first, one girl sickened on October 2nd; in the second, one girl sickened on October 10th; in the third, nine girls sickened, two on October 19th, two on October 21st, two on the 22nd, two on the 23rd, and one on the 24th; in the fourth, five girls were attacked, one on October 28th, two on October 29th, one on November 1st, and one on November 2nd; in the fifth, three girls were seized, one on November 7th (for the second time), one on November 8th, and one on November 11th. After this last date no further cases occurred. Allusion should be made to two instructive sequels to this epidemic. The first is the fact that diphtheria was carried home to the country in two instances by the girls when, nearly two months after their illness, the school broke up for the Christmas holidays. The second is the fact that nearly twelve months afterwards a little epidemic of a precisely similar nature occurred in the school. On September 30th, 1907, three cases of sore throat occurred in the school—the patients were moderately feverish, with swollen tonsils, enlarged cervical glands, but little or no exudation. The result of a bacteriological examination, made by Dr. Boxwell on October 1st, was to find the milder form of the diphtheria bacillus present in considerable quantities in two of the three cases. In the third case—clinically the most severe—Dr. Boxwell failed to find it, probably because streptococci and staphylococci were so numerous that they crowded out, as it were, the Klebs-Löffler bacilli—a fact well-known in true diphtheria. Lastly, the symptoms which by their more or less constant presence make up the clinical syndrome of diphtheritic fever are:—

1. A more or less severe coryza.
2. A moderate tonsillitis, usually one-sided, and unattended by high fever or by much exudation.
3. Thickly coated tongue and foul breath, the tongue desquamating as in scarlatina.
4. A patchy or punctate rash on the roof of the mouth and buccal mucous membrane.
5. Swelling of the cervical lymphathic glands.
6. A roseolar rash on the skin (in 12 out of 18 cases—in four cases early in the attack; in eight cases on the fifth to the seventh day from the first symptoms, or invasion).
7. Distinct desquamation (in three cases), the peeling being particularly marked on the hands.

Dr. **Kirkpatrick** said that sometimes 10 or 11 recruits came into Steeven's Hospital in one day from the Constabulary Depôt, complaining of symptoms resembling those described by Sir John Moore. They usually got well in a short time. In no case had there been any suspicion of membrane, and bacteriological examination showed no trace of the diphtheria bacillus in many cases. The organism in the majority of cases was some form of coccus. The condition was looked upon as an epidemic of catarrh, and in no case had been seen the roseolar rash, or the cervical glands materially enlarged.

Dr. **Burgess** said the recruits mentioned by Dr. Kirkpatrick were brought up from the country, and were not used to the ordinary hygiene. They were put on swimming lessons, and kept in the water for half an hour or more. This chilled them, and they complained of sore throats.

Dr. **Day** said it was not necessary to have a membrane to diagnose diphtheria. He had pointed out in a paper some years ago that cases having soft tonsils, coated tongue, and enlarged glands had given the diphtheria bacillus on a swab. Diphtheria was much commoner in the city than people supposed, and there were two main predisposing causes—bad teeth and constipation. The latter would explain the outbreak after the holidays. He thought the only way to get people free from the diphtheria bacillus was to give them change of air and occasional injections of, say, 500 units of anti-toxin prior to discharge from hospital. Since the anti-toxin treatment had come in, paralysis had been postponed. It was necessary to swab cases before applying any antiseptic treatment to the throat, and it was also more advisable to touch the red injected parts than to swab whatever membrane was seen. If there was nasal discharge, it was preferable to swab it than the throat.

Professor **White** said it was well to remember that the diphtheria bacilli were exceedingly susceptible to desiccation; they died more quickly than any organism of the same degree of virulence that he knew. Hence, in most cases that were swabbed in the membrane, it was possible that they got little away except some dry necrotic material which might contain bacilli alive and capable of reproducing themselves, but which would have died in a few hours because there was probably no moisture put in the swab. That might be the explanation of negative results of swabs taken from cases of severe diphtheria.

Dr. **Boxwell** said he would like to exonerate Sir John Moore and Professor White for the use of the word "attenuated" in his report. It was he (Dr. Boxwell) who had used it simply to describe a type of organism which he had often found in mild cases of sore throat. It was somewhat smaller than the typical bacillus, and in appearance like what was described as Hoffmann's bacillus. Not knowing whether it was the real diphtheria organism or not, he had called it an attenuated form.

Professor **White** said it appeared that there was some doubt as to whether the bacilli in the cases were diphtheria bacilli or not. There was no doubt whatever that some of the cases were due to the true diphtheria bacillus. The bacillus varied extremely, and he confessed to a difficulty in distinguishing between the form spoken of as Hoffmann's and the shorter forms of the bacillus.

The **Chairman** instanced an outbreak at a school in which definite membrane appeared in some cases. It was pronounced to be undoubted diphtheria. One boy admitted having had a slight sore throat at home during the preceding holidays. On examination, diphtheria bacilli were isolated. His own practice was to have a culture made in cases of follicular tonsillitis. He would like to know if, in any of the cases which developed in the country afterwards, there was a bacteriological examination.

Sir **John Moore**, in reply, said that constipation was very prevalent at the time of the outbreak of diphtheria. The toilet of the mouth was carefully attended to from the outset. He had found quinine to be a powerful disinfectant of the mouth. In nearly all cases the rash appeared before the anti-toxin was injected. Although Dr. Boxwell had used the term "attenuated," he submitted that the country cases which followed were perfectly conclusive as to the infecting organism, although he had no information that the diagnosis was confirmed by a bacteriological examination.

EYE-STRAIN AS A FACTOR IN THE PRODUCTION OF FUNCTIONAL NEUROSES.

Dr. **Kirkpatrick** read a paper on this subject, which will be found under the heading of "Original Papers," page 11.

Mr. **Mooney** also read a paper on "Eye-Strain," in which he expressed the opinion that the relation between headaches and errors of refraction was not as fully realised by physicians as it might be. His paper appeared in our last week's issue.

Dr. **Drury** quoted several cases in which attacks of migraine had ceased after the adoption of glasses for the correction of eye-strain.

Dr. **Henry** said there could be no doubt that in a very considerable number of cases of neuroses the symptoms were due to some affection of the eyes, and in some cases astigmatism would be found to be the cause. His own experience was that the affection of the eye which had most effect in producing headaches was a small degree of mixed astigmatism.

Mr. **Story** agreed that mixed astigmatism was perhaps a more common cause of headaches than simple astigmatism, and he also believed that difference in muscular balance was perhaps of even greater importance in the production of migraine.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

Meeting held at the Faculty Hall, Dec. 20th, 1907.

The President, Dr. **Walker Downie**, in the Chair.

Before proceeding with the business of the evening, the **President** made a sympathetic reference to the passing of Lord Kelvin. He recalled an occasion when Lord Kelvin—then Sir William Thomson—lectured to this Society on the diffusion of liquids and gases. He also remarked on the wonderful mental activity exercised by the late Baron up to the time of his last illness, and the sense of loss felt in the City and University of Glasgow.

Some interesting papers were then read and discussed, and card specimens were exhibited illustrating various surgical conditions.

A group of nine cases of

PULSATION IN THE WALLS OF THE PHARYNX

were shown by Dr. **James G. Connal**. This group comprised persons of both sexes, whose ages ranged from 10 to over 60 years. The pulsations were easily seen when the patient's tongue was well depressed and a good light thrown into the pharynx. In some of these cases the pulsation was unilateral, and in others it was bilateral. The commonest situation of the pulsation was just behind the posterior pillar of the fauces. This condition, though not unknown to both anatomists and laryngologists, has hitherto received little attention. Dr. Connal was of the opinion that this condition accounted for the excessive hæmorrhage sometimes encountered in operations upon the pharynx, and should always be looked for before operating in this region. The arteries that may give rise to these pulsations may be either the internal carotid artery or the ascending pharyngeal branch of the external carotid artery; but no explanation was given as to how this abnormal phenomenon was produced.

Dr. **Connal** then read an account of a case of "Chronic Purulent Middle Ear Disease," with involvement of the lateral sinus. Before opening into and evacuating the contents of the lateral sinus, he ligatured the internal jugular vein, a proceeding that he thought was justified by the satisfactory result obtained.

This paper was discussed by Dr. Walker Downie, Dr. Love, Dr. Eddington, and Dr. Barr, whose remarks were largely founded on their own experiences of similar cases.

Dr. **Archibald Young** showed a man with

MULTIPLE EXOSTOSES OF THE RIBS

and of the long bones. The patient had well-marked rhachitic deformities, and the interest of the case lay in the correspondence of the situations of the bony outgrowths with the usual sites of rhachitic deformity. Thus a long osteoma projected from one of the ribs at a point near to its junction with its costal cartilage. Another appeared over the tibial spine. The former began to grow when the man was 19 years of age, the latter when he was three years older. A large nodule on the clavicle began to grow three years ago, when he was 30 years of age. The other deformities of the bones were those of rickets rather than distinct tumours, and it was pointed out that the time as well as the distribution of the exostoses had a definite relation to the period when rhachitic deformity occurs.

An interesting discussion followed, in which Dr. A. McLennan and Dr. Eddington took part, and an explanation of such conditions was given by Dr. Ivy McKenzie, who described the anomalous manner in which bone is formed in rickets resulting in patches of unossified cartilage, which, after resting for some time, may again take on growth and become ossified when the conditions for so doing are favourable.

DOUBLE TUMOURS.

Dr. M. **Logan Taylor** gave a demonstration of microscopic and museum preparations of "double tumours." By this term Dr. Taylor did not refer to tumours composed of two or more different tissues, such as adeno-sarcoma, nor to "mixed tumours," such as are found in the parotid gland, where several kinds of tissue enter into the composition of the tumour. He wished it to be understood that double tumour meant a tumour that during its life history passed from one distinct type into some equally distinct but different type, or in some manner gave origin to such a different type of tumour. Cases of this kind were given, such as where adeno-sarcoma was cultivated for 40 generations in mice the carcinomatous element largely predominated. In one series of these experiments it was found that up till the twelfth generation the carcinomatous elements were in excess, about the sixteenth generation there was as much sarcomatous as carcinomatous elements; and in the fortieth generation the carcinomatous elements had almost disappeared, and the tumour was nearly all sarcomatous. In another series of cases the sarcomatous elements equalled the carcinomatous in the sixth generation, greatly exceeded them in the tenth, became entirely sarcomatous in the fifteenth generation, and continued thus till the fortieth generation. Cases in man were also given. In a case of primary carcinoma followed by secondary deposits and dissemination, the secondary growths in lymphatic glands were adeno-sarcoma, and the tumours formed by dissemination were pure sarcomata. Another form of double tumour was illustrated by a case where a melano-sarcoma affected the eyeball, which was excised in consequence. Deposits of melano-sarcoma were found in nearly every organ of the body, and where these growths were found in the liver primary carcinoma of the liver had occurred. The next case cited was that of a patient with a sarcoma of the mediastinal glands growing through the sternum, and at the same time having an adeno-carcinoma of the thyroid gland. These two tumours, arising separately in the same individual, extended till they became contiguous. In the discussion which followed this paper, Dr. Walker Downie referred to a case of cancer of the uvula in which the disease was removed, and in which there was a sarcomatous tumour removed from the neck seven years later.

Drs. G. **Buchanan** and **Wilson** also referred to a case where an epithelioma was removed from the back of the hand, and the whole limb had to be amputated later on for growths of sarcoma high up in the arm. Many of the microscopical preparations made from some of these cases showed two kinds of tumour occupying different parts of the same section.

A short communication was made by Dr. **Ivy McKenzie** upon

THE SPIROCHÆTA PALLIDA AND ITS ÆTIOLOGICAL RELATIONSHIP TO SYPHILIS.

These organisms were demonstrated to be present in abundance in the lesions of congenital syphilis, which were shown under the microscope. It was stated that the evidence in favour of spirochæta pallida being the ætiological factor in syphilis is increasing, while the opposite view is held by fewer observers, as their objections are being gradually met and answered by careful researches on the subject. The evidence, however, is not yet so complete as could be desired, as the organism has not been cultivated outside the living body, and inoculation experiments in animals only give rise to an indefinite kind of disease, with little resemblance to syphilis.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Meeting held at Manchester, Dec. 20th, 1907.

The President, Dr. E. O. Croft, in the Chair.

Dr. **Walter** (Manchester) (1) mentioned a case of

HÆMATOMA OF BOTH BROAD LIGAMENTS,

occurring a few hours after a supra-vaginal hysterectomy on a patient, æt. 37, who was exhausted by prolonged metrorrhagia. The tumour grew from the posterior wall of the uterus, and extended laterally to the sides of the pelvis. Incising the uterus deeply, the myoma was enucleated from its attachments, but general oozing from the broad ligaments gave trouble. The pulse was 84 at completion of operation; four hours later, 96; at 6 p.m. it was 116, and a small amount of blood was coming through the vagina. At 8 p.m. the patient became collapsed, and complained of abdominal pain. Saline injections were given, ether administered, and the abdomen opened. Not more than 8 oz. of free blood was found in the abdomen, but both broad ligaments were distended with blood and clots. There was no bleeding apparent from the main vessels, nor had their ligatures slipped. The collapse, simulating extensive hæmorrhage, was the chief interest in this case, and may have been due to intense pain from over-distension of the ligaments in a patient already debilitated by previous hæmorrhage.

(2) Particulars were also given of a case of

ABDOMINAL DISTENSION,

arising the day after supra-vaginal hysterectomy had been performed on a single woman, æt. 40, who sought relief on account of excessive menorrhagia and retention of urine produced by a myoma. The operation took place on October 29th, in the Trendelenburg position. Three hours afterwards the pulse was 88, and the patient fairly comfortable. The day following the abdomen was slightly distended, and flatus could not be passed voluntarily. The pulse gradually rose, and in the evening was 130; vomiting and pain were marked, and nutritive enemata were no longer retained. On the third day symptoms were more pronounced.

and the pulse 152. It was decided to open the abdomen unless some improvement took place. At 8 p.m. one of the enemas took slight effect, and the pulse fell to 140, and the next day to 128. Hot fomentations and gentle massage aided the ordinary treatment by enemata and calomel. The obstruction was possibly due to kinking of the intestines when being replaced after Trendelenburg's position. Both cases made good recoveries.

Sir **William Sinclair** (Manchester) mentioned a *case of gonorrhœa* and sepsis of the uterus in a patient, æt. 28. Seven years married. Repeated operations of curettage, and the removal of the uterine appendages had been carried out with little relief before he saw her on account of constant abdominal pain. On November 15th he extirpated the uterus per vaginam, and steady improvement followed. He advocated conservative treatment from the outset in these cases.

Dr. **Lloyd Roberts** (Manchester) related two cases of *Cæsarean section* for pelvic deformity, and showed the full-term fœtus, placenta and gestation sac, successfully removed by abdominal section from a patient who had an extra-uterine pregnancy.

Dr. **Arnold Lea** (Manchester) narrated two *cases of diffuse adenoma occurring in fibroid uteri*, and drew attention to the features of pathological interest in this condition. Multiple polypoid projections of the endometrium, microscopically of a benign character, were present. The uterine wall was uniformly thickened to the extent of 2 inches in some places. The specimens and microscopical sections were also shown.

Dr. E. **Emrys-Roberts** (Liverpool) gave a pathological report on a case of *primary unilateral superficial papilloma of the ovary*, and expressed the opinion that the ascites present in such cases was the result of secretion by the epithelium covering the papillæ. Lantern slides were shown. The tumour was removed by Professor Briggs in the Hospital for Women, Liverpool.

Dr. **John Cameron** exhibited a number of dissections demonstrating the *supports of the pelvic viscera.* After pointing out that the muscles forming the pelvic floor in man were now recognised as vestigial structures, he directed attention to the fact that we must regard the fascia surrounding the visceral branches of the internal iliac vessels (the perivascular fascia) as forming the most important support of the pelvic viscera both in the male and in the female. He then went on to suggest that operative treatment for prolapsus uteri must be directed not to the pelvic outlet alone, but also to this perivascular fascia.

CENTRAL MIDWIVES' BOARD.

Meeting held December 19th, 1907.

Dr. Champneys in the Chair.

The principal matter dealt with by the Board was one arising out of a report from two of the Manchester Examiners as to the insufficient training of a candidate at the October examination. The question was debated for some time *in camerâ*, after which the following statement by the Chairman was communicated to the Press. In view of its importance this statement is given in full:—

"Drs. Stallard and Wallace, two of the Manchester Examiners, have reported as follows with respect to one of the candidates examined by them at the October examination:—'No 42 has only attended 15 cases personally (10 in hospital and 5 in district), although she was signed up for 20. Has not fully attended a course of lectures. Quite ignorant of fœtal skull and pelvis, and of normal body temperature. Does not know how to deal with post-partum hæmorrhage, and has hazy ideas on most subjects.' No. 42 was Elizabeth Christiana Myerscough.

"No candidate can be admitted to an examination of the Board unless she produces certificates—(*a*) of having attended and personally delivered 20 cases; (*b*) of having nursed 20 lying-in women for the 10 days following confinement; and (*c*) of having undergone a three months' course of instruction. The three certificates of training comprised in Miss Myerscough's schedule were each signed by Dr. Thomas G. Stevens, Master of the Coombe Hospital, Dublin, and she was admitted to the examination in virtue of these certificates. The candidate herself had signed the declaration that the certificates signed by Dr. Stevens were in all respects correct and true.

"The Secretary communicated with Miss Myerscough, and, after some difficulty, ascertained from her that her statement of having conducted 15 labours only was true. She added that the matron, although she knew she was entering for the Central Midwives' Board's examination, informed her that 15 cases would be sufficient. Her excuse for having signed the declaration was that she had no idea that the Board would be so particular. She stated finally that she did not wish any publicity to be given to her name should the matter be taken up by the Board.

"The Secretary then wrote to Dr. Stevens informing him of Miss Myerscough's statement to the examiners, and that she adhered to it, and asking him for his explanation of the circumstances. A reply was received from the Registrar of the Coombe Hospital which merely stated as regards the point at issue that Miss Myerscough was credited in the books of the hospital with having attended and watched the progress of not fewer than 50 cases, of which she had had personal practical experience. A further letter from the Secretary pointed out that this was no answer to his previous letter, and stated that what the Board wished to know was whether Miss Myerscough's statements were true, or whether she had, in fact, personally delivered 20 cases.

"To this a reply was received from the Registrar, of which the following are the material extracts:—

> "'The Master desires me to say that in signing the certificate he was aware that Nurse Myerscough had conducted 15 cases, but, being present and having had practical personal experience of such a large number extra, he considered he was entitled to sign the certificate, and that in doing so he complied fully with the spirit of the rule. . . . In conclusion, the Master desires me to say that if 15 conductions, as well as a large number of attendances of which the nurses have personal practical experience, are not considered sufficient by your Board, the hospital will at once make arrangements to see that each nurse in future conducts at least 20 cases.'

"Dr. Stevens accordingly admits that he signed a certificate stating that Miss Myerscough had, under his supervision, attended and watched the progress of not fewer than 20 labours, and had personally delivered the patient, knowing perfectly well that she had conducted 15 cases only.

"The signing of a false certificate, knowing it to be false, appears to fall within the class of offences included in Section 22 of the Midwives' Act, 1902. This section is as follows:—'Any person wilfully making or causing to be made any falsification in any matter relating to the roll of midwives, shall be guilty of a misdemeanour, and shall be liable to be imprisoned with or without hard labour for any term not exceeding 12 months.' This section is printed *in extenso* and in conspicuous type at the bottom of that page of the schedule which contains the three signatures of Dr. Stevens and the signature of Miss Myerscough to the declaration.

"Dr. Stevens' conduct in signing this false certificate is such that no words of comment are necessary. Such a flagrant breach of the law, however, requires drastic action by the Board, and I move accordingly:—

"(*a*) That the name of the Coombe Lying-In Hospital be removed from the list of recognised training-schools.

"(*b*) That Dr. Stevens be informed that no certificate signed by him will be accepted by the Board in future.

"(*c*) That Elizabeth Christiana Myerscough be informed that she will not be admitted as a candidate at any future examination of the Board unless she produces a fresh schedule showing that she has undergone a complete course of training elsewhere than at the Coombe Hospital.

"(*d*) That the facts and documents relating to the case be reported to the General Medical Council and to the Privy Council."

Other correspondence dealt with by the Board included letters from Mr. W. Schröder, Deputy Coroner for Central London, and Hon. Secretary of the Coroners' Society, asking the Board to furnish the Coroners of England and Wales with an annual copy of the Midwives' Roll, or in the alternative that the local supervising authorities of England and Wales should furnish copies of the local rolls.

The matter was referred to the Privy Council.

Letters from Dr. G. Sydenham were discussed, as they related to the term infectious disease as employed in the rules, whether they included such diseases as measles and whooping-cough. It was agreed that no definition could be made by the Board, and that Dr. Sydenham be referred to the rules as regards the necessity for disinfection, and to the local supervising authority as regards the method and cost of the same.

There was also a letter from the Clerk of the Council transmitting a copy of a letter from the Local Government Board enclosing a letter from the Executive Committee of the Rural Midwives' Association in regard to the question of the training of midwives, and the possibility of the grant of State aid towards the cost of such training. This was referred to the Standing Committee.

Dr. Rahim, of Commercial Road, had written to ask whether the midwife employed by him to do some of his midwifery cases could not be exempt from inspection, as it added to the work of a general practitioner. The request, however, could not be granted, as the woman practised as a midwife, and not as a maternity nurse.

The following motions, put forward by Dr. Stanley Atkinson, were carried :—(1) That in the case of a midwife struck off the roll upon consideration of depositions taken at a Coroner's inquisition, the Coroner be informed of the result. (2) That upon application being made for the restoration of the name of a midwife to the roll, the local supervising authority under which she practised be notified of the fact at once.

Dr. Wright, of Derby, was approved by the Board as a teacher *pro hac vice*. The Birmingham Maternity Hospital was approved as a training school. The following were appointed examiners to the Birmingham centre:—F. Edge, E. Malins, C. Martin, J. Wilson and Jordan Lloyd were to be asked to accept the appointment.

The date of the next meeting was fixed for January 16th.

CORRESPONDENCE

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Dec. 29th, 1907.

Prophylaxis of Gonorrhœa.

Quite recently Roux and Metchnikoff drew, for the second time, attention to the utility of calomel ointment (33 per cent.) as a prophylactic agent of syphilis, which if applied after coitus seems to grant immunity. Gonorrhœa being one of the commonest forms of venereal disease, and frequently followed by grave complications, it may be interesting to give a *résumé*, according to Tausard, of the different means recommended as preservatives against the affection.

Condoms are useful, but are liable to tear in use. The advice to micturate immediately after coitus is good, but it is not necessarily efficacious, as the microbes can localise themselves on the lips of the meatus and on the mucous membrane. Antiseptic lotions of the glans, with a solution of permanganate of potash, oxycyanide of mercury, or protargol, are better as precautionary measures. But these different methods are far from being infallible, and have been more or less replaced by injections, instillations, or ointments.

Welander advises an injection after coitus of a solution of protargol, 1—25. Frank utilises also protargol, but much stronger, 1—5.

Guiard employs permanganate of potash in very weak solution (1—10,000), of which from eight to ten injections are given successively, and the operation repeated two or three times in the day.

Zeissel uses a glycerine solution (1—5) of protargol, of which 5 or 6 drops are injected into the navicular fossa. In Germany specially prepared tubes filled with this solution can be found.

Tandler employs the same solution, but injects it by means of an ordinary drop tube.

Salmon and Rheusse prefer a solution of protargol and vaseline oil. They advise injecting a few drops before coitus, and after washing with a solution of corrosive sublimate the glans, follow this by an injection of protargol.

Tausard considers that a weak solution of protargol (1—50) is quite sufficient, and the strong solution, if frequently repeated, would set up irritation of the canal, terminating finally in stricture.

Pruritus of the Anus.

Pruritus of the anus is more of an inconvenience than a malady. It is met in gouty, arthritic persons, and accompanies hæmorrhoids, threadworms in children, and eczema of the region. The affection is, as all know, very tenacious and rebellious to treatment. A good method is to apply in the evening a very warm solution of phenic acid or poultices, especially if eczema be present. After the fomentations the following ointment gives some relief :—

Ess. of peppermint, 15 drops.
Lanoline, 1 dr.
Vaseline, ½ dr.
Olive oil, ½ dr.

Brocq advises also, suppositories :—

Cocain. ½ gr.
Morphia, ½ gr.
Cacar b., 1 dr.

If the itching is produced by ascarides, calomel ointment should be applied, and santonin with calomel given internally :—

Calomel, 1 gr.
Santonin, 1 gr.
Sugar, 10 gr.
For one powder, No. 3, one each night.

If the pruritus is associated with hæmorrhoids, the following ointment, applied morning and evening, will be found useful :—

Tinc. of benzoin, 2 dr.
Ext. of hamamelis, 1 dr.
Ergotine, 1 dr.
Phenic acid, 10 gr.
Lanoline, 5 dr.
Vaseline, 5 dr.

Some very obstinate cases will only yield to linear scarifications.

Acute Coryza.

Sulph. of atropine, 1-5 gr.
Cherry laurel water, 5 dr.
Water, 5 dr.

Pour a few drops into a teaspoon, and dip into it the end of a match covered with a little piece of absorbent wool rolled tightly around it. With this simple instrument the mucous membrane of the nose is touched every hour by the patient himself during the daytime. If by the third day no relief (which is unlikely) is obtained, the treatment should be discontinued. A few drops of tincture of aconite in some warm infusion taken at bedtime procures perspiration and adds materially to the effect of the local treatment.

A good means of relieving the painful sensation of nasal obstruction is to sniff up a few drops, three times a day, of the following solution :—

Solution of adrenalin (1—1,000), 10 drops.
Solution of cocaine (1—100), 5 dr.
Cherry laurel water, 5 dr.

Not to be employed in children.

GERMANY.

Berlin, Dec. 29th 1907.

From a decision given some time ago in a court of law, a landlord of a house in Germany that has been occupied by a medical man who has left that house and gone to another is bound, although no special contract has been entered into regarding the matter, to allow the departing tenant to put up a notice-board on the house, and keep it there for a certain specified period, announcing the fact of his departure and his new address.

A SOCIETY FOR THE CARE OF INFANTS.

A Society for the Care of Infants (Verein für Sauglingsfürsorge) has been founded in the Düsseldorf district of Germany. The Society commences with a capital of 500,000 marks and a valuable piece of ground. The current expenses will be borne partly by the city and partly by the district. An intimate connection will be established between the Verein and the Academy for Practical Medicine. The Director of the Klinik for Diseases of Children will also be the scientific director of the Society. Some of the buildings have already been erected. The President will be Professor Schlossmann.

At the Medical Society Hr. Carl Levin spoke on the morphology and biology of malignant tumours. He spoke of the great difficulties that had been encountered in the transference of malignant disease from one animal to another, and laid stress on the fact that even when this had been accomplished in the case of classes of animals nearly allied, the whole group of symptoms of malignant disease were but rarely met with. The speaker had succeeded in cultivating a mammary carcinoma of a rat through thirteen generations, anatomical carcinoma with metastases in the abdominal organs being produced in every case. The case was originally an adeno-carcinoma. In the third generation a cancroid suddenly developed at the inoculation point, and from that time onwards during the succeeding generations either a tumour of mixed form —adeno-carcinoma and cancroid—or one of the two forms developed singly. It was certain there was nothing of cancroid in the tumour originally. Either a metaplasia of the cancer cells took place subsequently, or the cancroid arose from the irritation set up by the cancer cells upon the epidermis. The stroma developed freely in patches in the carcinoma, with occasional accumulation of spindle cells, which increased without any interval of granulation tissue to be seen.

Contrary to the experience of other observers in the case of mice (L. Michaelis), in rats breed and descent made no difference as regarded either susceptibility or growth of tumour. The most susceptible were young rats five to seven weeks old. He had had only 10 per cent. of failures in his inoculations. If the animals were first inoculated with hæmorrhagic tumours difficult to transmit (Ehrlich), or the first inoculation failed from any other cause, further inoculations were also failures. He looked upon this as an acquired immunity. In the same way mice were not susceptible who had previously been inoculated with rat tumours, and inversely rats were not susceptible when they had been first inoculated with mouse tumours.

At the Aerztlicher Zentralverein in Olten, Professor Roux spoke on his experiences with

ILEOCÆCAL TUBERCULOSIS.

since the Tuberculosis Conference in 1905. The right iliac fossa he looked upon as the key for investigating the condition of the various organs (gall bladder, ovary, right kidney, bowel). He pointed out the possibilities of palpation of the cæcum where in case of disease tumour formation or infiltration was rarely absent. In all his cases the disease could be recognised by palpation; 14 patients suffered from pain in the right iliac fossa; in 7 cases there were plain signs of stenosis; whilst the remaining 10 only suffered from constipation. Most of the patients were between 20 and 30; only two had advanced beyond the 6th year. Heredity could be shown in 7 cases; in 2 it was doubtful; in the remainder there was no trace of it. All the patients were treated surgically. In 7 he found multiple tuberculosis of the bowel, mostly with participation of the serous covering. If there were adhesions they were always in the right iliac fossa—nowhere else; 7 patients were suffering at the time from advanced tuberculosis of the lungs; the others showed only slight changes there, or none at all. Diffuse, multiple ulcers were only met with in association with advanced disease of the lungs—cavities, etc. He had performed the radical operation in 13 cases. When the ileum was wide enough, end-to-end anastomosis could be performed; otherwise the other forms were preferable. In his operations he had always made use of the incision he had recommended for operations on the appendix. In order to get more room you could then turn in the sheath of the rectus. Of palliative operations the taking out of a portion was the best; entero-anastomosis, on the other hand, was of but little value, as it only relieved the stenosis and did not influence the disease. In his operations for ileocæcal tuberculosis there was one death. Early diagnosis was important, as it allowed early operation. For this palpation was always of the greatest importance. The family doctor should never omit to palpate the right iliac fossa, as it often afforded indications for operation when other symptoms failed to give the necessary clue.

AUSTRIA.

Vienna, Dec. 29th, 1907.

FISTULA GASTROCOLICA.

AT the "Gesellschaft" Eiselsberg gave a history of the treatment of a case of ulceration of the stomach terminating with a fistula into the colon. The first palliative operation was a colostomy or jejunostomy, the former into the ascending colon, while the radical operation of colo-colostomy with resection of the primary fistula had finally to succeed these palliative measures.

MORPHOLOGY AND ÆTIOLOGY OF SEXES.

Tandler and Gross next entertained the meeting with the results of their investigations into the secondary effects of sexual operations such as castration, etc. They exhibited a eunuch, æt. 28, along with another negro, æt. 28, from Zanzibar. The castration of the eunuchs is usually performed when the child is six or seven years old.

In the comparison nothing very striking could be observed about the head unless the ossification which was niversally affected. The larynx was small, resembling a boy of twelve, while all the internal genitals are equally backward, the prostate being very small. The general configuration of the pelvis was between a male and female. The epiphyses of the humerus, ulna and radius, etc., were all apparently jointed. Two crania of castrated negroes were shown to demonstrate the same inhibitory action in the calvaria as present in the long bones. The pelves had the same defects. They next presented the bones of sheep that had been castrated along with those that had not been castrated. They also showed the pelvis of a man, æt. 54, with epiphyseal junctions of the pelvis, who presumably suffered from agenesia of the testes. From these facts Tandler and Gross reason that the bones never reach perfect ossification till the function of the glandula genitalis is fully matured.

Tandler and Gross are of opinion that this secondary effect is not only an inhibition or checking of the growth, but rather a perversion of the phylogenesis in the several organs. The genital glands of the sheep were neither masculine nor female, but rather a peculiar asexual form. For example, the larynx is neither male nor female in character, but rather an immature condition of the organ. The castrated pelvis has the same immature appearance, resembling neither one sex nor the other. The thymus in the castrated remains longer than in the normal state, thus indicating the immature condition of the individual. The great increase of the hypophysis after castration was early observed by Fichera, and needs no further description than by saying it is a peculiar symptom in castration.

Schüller said that besides the peculiar formation and proportionately large size of the castrated skeleton the peculiar structure of the bone itself was diagnostic of castration which could be detected with the assistance of the Röntgen rays. Redlich had recently published a case of "Giant Growth in the Infant" where the Röntgen rays revealed the presence of diffuse atrophy in the skeleton. These cases all prove to us that besides the thymus and hypophysis of bone being affected, the marrow of the bone is adversely affected by any interference with the cellular glands in other remote parts of the body.

Cramps and Convulsions.

Benedikt raised the question of locating cramps in the nerve system. The function of the nerve on the muscle was threefold—(*a*) shortening of the muscle, (*b*) an extension or broadening of the muscle to bring the body into the upright position, and (*c*) the fixation of body.

We now know that the cerebellum and medulla oblongata are responsible for the power of erection or elevation, and that all cramping arises from muscular shortening. In the case of paralysis agitans the cramping centre is apparently in the region of the quadrigemina. In chorea major the cramp assumes the character of a wave movement, while in the minor form it appears in irregular contractions. From this Leyden assumes the centre is located in the pulvinar or cerebrum, while the minor is in the cerebro-spinal axis. Isenschitz said that clinicians did not consider chorea major and chorea minor two separate diseases, and why they should have two morbid centres would be difficult to explain.

Rhachitis.

Goldreish exhibited an eight-year boy with tardy development of the permanent teeth. He was scarcely 93 ctms. instead of 119 ctms. with all the signs of rhachitis. At his age the four incisors and first molars should be appearing, and he considered the delay due to the rhachitis. He believed that phosphorus therapy would be successful in this case. Escherisch thought the rhachitis was very slight and the retarded teeth due to hypothyreoidism or some other congenital anomaly. Kasowitz was opposed to this view, and believed that rhachitis was the sole cause in the retardation of the teeth.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

SERIOUS POSITION OF MEDICAL TEACHING IN CONNECTION WITH GLASGOW UNIVERSITY AND THE ROYAL INFIRMARY.

Considerable interest is being taken at present in medical and other circles in Glasgow and the West of Scotland with regard to the future relations of the Royal Infirmary and its Medical School, on the one hand, and the utilisation of the Royal Infirmary by Glasgow University for teaching purposes on the other. Briefly, the facts are as follows:—When Glasgow University was transferred to Gilmorehill in 1874, the then managers of the Royal Infirmary considered it essential, in the interests of the Infirmary, that it should possess a Medical School of its own, and the "Glasgow Royal Infirmary Medical School" was finally established, in the face of the strongest opposition from the University authorities. In 1889, at the instigation of the Royal Infirmary managers, the School was constituted a College (St. Mungo's College), so that the affiliation clause of the Universities Act of that year might be applied towards the affiliation of the Medical School to the University. But affiliation has all along met with the strongest opposition from the University authorities. In spite of this, St. Mungo's College was for a number of years a flourishing medical school in connection with the Glasgow Royal Infirmary. In more recent years, partly owing to the increased facilities for complete medical education in England and Wales generally, but more particularly owing to the operations of the Carnegie Trust acting unfavourably with regard to extra-mural students of medicine, the number of students in attendance has diminished, and for some time it has been evident that some form of reconstruction or affiliation was necessary if the school was to be continued on a permanent basis. Suggestions for the affiliation of St. Mungo's College to the University have met with very negative encouragement on the part of the latter, although no definite scheme of any kind has as yet been propounded to the University Court. On the other hand, suggestions emanating from University quarters have been made that the wards of the Royal Infirmary should be utilised for the purpose of affording additional clinical facilities for University students, while as a *quid pro quo* the University might appoint a certain number of teachers in the Infirmary as University lecturers, these lecturers to be examiners in virtue of their appointment, and to have in this respect equal status with the University professorial staff. While, of course, there are arguments on both sides which can only be finally settled by the arbitrament of time, there are some features which show a distinct analogy with the cases of the London Medical Schools, and differ materially from the cases of Birmingham, Manchester, Liverpool, and other centres which have been cited in favour of what is euphemistically termed "co-ordination" in medical teaching. The Royal Infirmary is the largest general hospital in Scotland, the number of beds occupied being somewhere between 600 and 700, and therefore seems *a priori* to have a good case for the possession of a Medical School of its own. The Western Infirmary, where at present practically all University students get their clinical teaching, contains somewhere between 400 and 500 beds. The other essential point is that the Royal Infirmary is about three miles from the University, while the Western Infirmary is practically in the University grounds. Now it is clear that students cannot be expected to waste hours of valuable time daily in travelling between the two Infirmaries, and as the University has no power to compel its students to go outside the Western Infirmary for their clinical teaching, the only practical remedy appears to be that the Royal Infirmary should continue to maintain a complete Medical School of its own. This, indeed, seems to be fairly generally recognised in Glasgow, and the two stumbling-blocks are the financial difficulty and the actual though unacknowledged hostility of the University to affiliation. On the general question of the interests of medical education, it does not seem too much to imagine that Glasgow and the West of Scotland ought to be able to accommodate at least two complete Medical Schools; and, to secure really effective competition, these schools should be on terms of affiliation. No surprise need be felt that the University probably does not look upon the matter in this light. The annual meeting of the qualified contributors to the Royal Infirmary, which takes place in a few weeks, and which may decide the future destiny of the Infirmary with regard to its Medical School, will be awaited with very great interest in many quarters.

Notification of Births Act in Scotland.—A representative deputation of the Glasgow medical profession was received by the Health Committee of the Glasgow Corporation on December 24th, in view of the coming into force of the Act on January 1st. In a memorandum the deputation state that whilst they have entire sympathy with the object of the Bill—namely, the reduction of infantile mortality among the poorer or less informed members of the community—they are of opinion that the means by which this is sought to be attained in the Notification Act in the form in which it has emerged from Parliament are in certain respects of a highly objectionable character. The provisions of the Act involve, in many instances, an unnecessary invasion of the homes of the citizens, and they place the family doctor in the position of a spy and informer in relation to his patients. Under the oath which has been imposed upon members of the medical profession from time immemorial, every medical man, upon his entrance into the profession, declares that he will not knowingly or intentionally do anything to the hurt or prejudice of persons committing themselves to his care and direction, "for any consideration or from any motive whatever," or divulge any secret committed to his charge. The requirements of the Act, if pressed indiscriminately, will in certain instances involve consequences of the most distressing character. There will be cases—not, unfortunately, very uncommon—in which young girls in respectable families would come within the purview of the Act under circumstances of shame and anguish. It may be taken for granted that members of the medical profession in such cases may not be deterred by any fear of the imposition of penalties from fulfilling the obligations of the medical oath. In conclusion, the medical profession of Glasgow, believing that the Corporation will act with discrimination in administering the Act, propose in case of each birth in connection with which they are called in, to place in the hands of the father or other responsible person a simple form of notification, with directions for its transmission to the Medical Officer of Health. They respectfully invite the Corporation, without adopting any resolution on the subject, to accept such notification as falling within the scope of the exemption clause of the Act, which is that no person shall be liable to a penalty if he has reasonable grounds to believe that notice has been duly given by some other person. The deputation were thanked and assured that the Committee would fully consider their statements.

OBITUARY NOTICES of the late Sir Patrick Heron Watson and of Professor Annandale, will be found in another column of our present issue.

LETTERS TO THE EDITOR.

MALIGNANT ANTI-VIVISECTION FANATICISM.

"VIVISECTION.

"To the Editor.

"Sir,—Instead of unseemly riots by medical students, and heartless jesting about one poor, helpless, pitiful little martyr to so-called science, let them do all in their power to make an end of the vivisection of dogs, which is carried on to such an appalling extent in the laboratories and medical schools.

"Most of these young men have, no doubt, had—and loved—dogs of their own. How, then, can they endure to witness the vivisection of other dogs, bound down, and maimed, and mutilated in the most terrible and revolting manner before their eyes?

"If all medical students would adopt the noble and manly course of refusing to attend classes where dogs are used for demonstration of lectures, and of declining to have anything to do with the cruel, vile, base and degrading practice of vivisection, they would gain infinite credit and honour for themselves and for the profession they intend to enter, which is now so very deeply disgraced by the foul blot of animal torture.—I am, etc.,

"C. A. M. BAILEY,
"Hon. Secretary, National Canine Defence League."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The above is an extract from a letter taken from the local paper of this date, December 20th. I am informed that letters of this kind are sent out wholesale to the provincial Press, and find a place in most of them. The letter constitutes a malignant and atrocious libel on physiological workers, on students of medicine, and on the whole profession. You will notice the false statements, particularly that which speaks of students "witnessing the vivisection of dogs bound down, and maimed, and mutilated in the most terrible and revolting manner before their eyes." The whole thing is calculated to inflame the minds of the public against the profession, to excite suspicion, distrust, and hatred of medical men. I repeat the query of your correspondent whose letter appears in your last issue, "Is it necessary that the profession should take all this lying down?" The papers that print these calumnies have their columns full of quack puffs, many disparaging doctors, and trading upon the fears of simple and ignorant readers—such an advertisement as you will see is printed below the letter I send. Vast numbers of poor people are to be found with organic pathological mischief, or malignant disease, gradually passing beyond the reach of remedy, whilst reliance is being placed upon worthless heal-alls and nostrums of one kind or another. The amount of human suffering and misery to which the anti-vivisection propaganda is giving rise in these islands alone exceeds a thousandfold the pain inflicted in the whole of the physiological laboratories throughout the civilised world. It is impossible for single individuals to combat this evil; local practitioners certainly cannot do it. Their appearance in the public Press at once lays them open to the imputation that they seek a personal advertisement. This is at least enough to deter me from such a course, and hence my appeal to you, Sir, for guidance and help. Is no organisation of the profession possible to deal effectually with the evils I write about? Ought we not, for the sake of humanity, and for our own sakes at least, to show fight in the cause of justice and truth?

I am, Sir, yours truly,
A SURREY DOCTOR.

Near Reigate, December 20th, 1907.

TREATMENT OF ARTIFICIAL ABSCESS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—On page 614, of THE MEDICAL PRESS AND CIRCULAR, December 4th, 1907, in your "Special Correspondence from France," reference is made to a certain method of treatment by artificial abscess, made by injection of 20 drops of sterilized turpentine. I beg to inform you that I have been using for this purpose a much better medium, pure culture of yeast cells; made according to the process of Prof. Christian Hansen, of Copenhagen, Denmark.

I am *curing* leprosy by this means; that is, my cases are steadily progressing favourably; all lesions are healing. 2 c.c. of these cultures ice cold, fresh from the single cell (unbudded) cultures, are injected mixed with vaccines, procured in the following manner. A first injection is made with the yeast cultures; beneath a prominent leproma this abscess is aspirated, and the contents dried, washed, sterilized, then emulsified to more 2 c.c., with strong camphorated oil. The second abscess, beneath a leproma produced by this, is again aspirated, and thus the treatment is continued. The area of inflammation is sometimes excessive, almost erysipelatous in character; and I note that, following this extended irritation thus set up, the best results are obtained in healing the open lesion of leprosy. The good effects of each vaccination by this method continue about 12 days, when a new abscess with yeast culture cell, leucocytes and dead bacilli, must be created. I find this a good method of training the leucocytes to kill the leper bacilli. The yeast cells remaining in these abscess cavities, by methylene blue staining, are shown to be dead; the enzymes by testing on sugar solutions are found to be still living. Chaulmugra oil will kill yeast cells and not enzymes, and this is our best remedy against leprosy. Thus the improved condition resulting from the one remedy must be in some way like that of the other. If the leucocytes can kill the yeast cells when thus drawn to an infected leprosy area, may they not at the same time act inimically against the leper bacilli? Evidently they do, for the cases in which I have used the method are continuing to improve rapidly.

ALBERT S. ASHMEAD, M.D.

New York, December 20th, 1907.

THE HEREDITY OF SYPHILIS

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to your report of my remarks on congenital syphilis and the question of the "heredity of syphilis," may I be allowed to call the attention of your readers to the masterly and exhaustive critical examination of this subject, especially as regards Colles's law, by Matzenauer? Matzenauer's "Die Vererbung der Syphilis" (Wien, 1903) is deserving of study by all medical men interested in the matter. The same author's "Die Vererbung der Syphilis: Ist eine paterne Vererburig erwiesen?" and the discussion which took place before the Imperial Society of Medicine in Vienna in 1903, are also well worthy of study ("Wiener Klin. Wochensch.," 1903).

I am, Sir, yours truly,
GEORGE PERNET.

London, W., December 30th, 1907.

OBITUARY.

PROFESSOR ANNANDALE, OF EDINBURGH.

PROFESSOR THOMAS ANNANDALE, whose sudden death on the morning of December 20th caused such universal grief in professional and social circles, and came as a great shock on the many friends who had seen him at work as usual on the day previous, was born in Newcastle in 1838, and had just entered on his 70th year. He was educated in his native town, and studied medicine first at Newcastle, subsequently at Edinburgh University, which he entered in 1856. From his student days he evinced a remarkable aptitude for surgery, combining dexterity, resourcefulness, and boldness in a remarkable degree—faculties which, along with his marvellous precision and neatness in operating, served him well until the end, and seemed rather to be sharpened than blunted by the passage of years. Though not trained in the pre-anæsthetic school, he was yet sufficiently near it to have acquired from those who practised then the art of rapidity in operating, on which so much of the success of earlier surgery depended. He graduated with honours, and received a gold medal for his thesis on injuries and diseases of the hip. At the same time he became a member of the College of Surgeons of England, and in 1860 served under the late Professor Syme as house surgeon. Syme undoubtedly was the teacher who most guided Annandale's bent, and many were the references the latter used to make to "my old master, the late Mr. Syme." So impressed was Syme by his young house surgeon's surgical instincts that he made him his private assistant, and in this capacity Mr. Annandale acquired a very large and varied experience of surgical practice. Mr. Syme died in 1870, and five or six years before that, Mr. Annandale, who had meanwhile been awarded the Jacksonian Prize by the English College of Surgeons, was appointed assistant surgeon to the Royal Infirmary. In 1863 he began to lecture on systematic surgery, and in 1871, when he became full surgeon, he gave this up for clinical surgery. When Lord Lister left Edinburgh for King's College in 1877, Mr. Annandale was elected to succeed him in the Chair of Clinical Surgery. It is a striking coincidence that his chief rival in the competition for that chair was Sir Patrick Heron Watson, whose death followed so closely upon the heels of that of Mr. Annandale. For the remaining 30 years of his life his whole energies were thrown into the conduct of the class of Clinical Surgery.

Professor Annandale taught his students many lessons, and not least of these was courtesy. It is impossible to conceive of him as anything but unvaryingly polite to his patients, from the humblest to the highest. His constant good humour and fund of anecdote enhanced the attractiveness of his teaching, and never detracted from his dignity. His relations with the students were of the happiest character, and his influence among them for good was all the greater that it arose from example and from the innate kindliness of his disposition, and was never enforced by prosy moralising. Professor Annandale was a brilliant operator. He was at his best in operations which demanded neatness and dexterity, and was especially successful in dealing with extensive malignant disease of the mouth and jaw. Various plastic operations, too, were his *forte*. In certain directions his powers of diagnosis were so remarkable as almost to merit the adjective "intuitive." Among his chief literary contributions works on diseases of the fingers and toes, on diseases of the breast, and on surgical appliances and minor surgery may be mentioned.

He was Surgeon-General to H.M. Bodyguard for Scotland, the Royal Archers, and took a prominent part in the social life of Edinburgh. All his old students will feel that, through his death, the University is poorer by the loss of a brilliant surgeon and a courteous gentleman.

SIR PATRICK HERON WATSON, OF EDINBURGH.

It cannot be said of Sir Patrick Heron Watson, as it was of Professor Annandale, that he actually died in harness, for although he was in active work until comparatively recently his health had been failing for some years, and within the past week his malady—angina pectoris—underwent a change for the worse, so that his death on December 21st was not wholly unexpected. Sir Patrick Heron Watson was the son of the Rev. Chas. Watson, D.D., parish minister of Burnbeland, and was born in Edinburgh in 1832, being at the time of his death within a few weeks of the completion of his 86th year. Educated at the Edinburgh Academy and University he graduated at the age of 21, and two years later, in 1855, became a Fellow of the Royal College of Surgeons. Watson determined to join the Army Medical Service, and went immediately after graduation to Woolwich, where his abilities were so speedily manifest that at the desire of the powers in authority he conducted a class of operative surgery for over a year. Becoming an assistant surgeon in the Royal Artillery he embarked for the Crimea, where he was first delayed from going to the front by an attack of typhus, and later, while his battery was guarding the Traktir bridge, he was debarred from active service by dysentery. Soon afterwards he was invalided to Scutari, when he heard the doctors discussing his case say "The man is too ill to survive the night." On his return to Edinburgh Dr. Watson began to build up what was probably the largest medical and surgical practice which has ever existed in Scotland. He taught surgery in the extra-mural school, he became assistant surgeon to the Royal Infirmary, he practised ophthalmic surgery in the Eye Infirmary, and he was likewise surgeon to Chalmers Hospital. He edited an edition of "Miller's Surgery," at the time the standard surgical text book. For various reasons, while Patrick Heron Watson's name was a household word throughout great part of Scotland, it has been but a tradition to many generations of students. He attained fame and an outstanding position in the medical world at an age when most men are only beginning to win their spurs—he retired from the infirmary after completing his tenure of office as senior surgeon at the age of 47; thirty-five years ago, when he was conducting a most extensive practice, specialization was in its infancy, and his opinion was sought after in medical and surgical cases, in which for the next twenty years his position as a consultant was undisturbed. His determination not to specialize militated against his obtaining that official recognition and position in surgery which his undoubted abilities and powers so well deserved.

Sir Patrick Watson filled many public offices and received many dignities. He was twice President of the College of Surgeons, being elected for the second time on the occasion of the quatercentenary. He was a curator of patronage of the University of Edinburgh, a Fellow of the Royal Society, and a member of the General Medical Council for many years. He was an LL.D.Edin., and Hon. Fell. of the Royal College of Surgeons of Ireland. He was one of the honorary surgeons in Scotland to H.M. Queen Victoria, and held the same honour at the hands of our present sovereign. In July, 1903, he received the honour of knighthood. He was universally respected, and was a quite unique figure in the medical world. However eminent physicians and surgeons we shall have in the future, it is certain that changing times will prevent any one man from filling the place left empty by Sir Patrick Heron Watson's death.

SIR ALFRED B. GARROD, M.D., F.R.S.

We regret to announce the death of Sir Alfred Baring Garrod, which occurred on Saturday last at his London residence, 10, Harley Street. Deceased was educated at King's College Hospital, graduating as M.D. of the London University in 1843. He became a Fellow of the Royal College of Physicians in 1856. Dr. Garrod was early placed upon the medical staff of King's College Hospital, and was Professor of Materia Medica and Therapeutics and of Clinical Medicine in the College. His attention was very early directed to the study of gout, and he endeavoured to confine the name to a specific condition in which the presence of lithate of soda in the blood could be demonstrated by the crystallisation of this salt upon a fibre of thread placed in a small amount of blood serum. This direction of his energies soon opened the way to a large and lucrative practice, and increased opportunities only added to his endeavours to solve the many problems connected with gouty and rheumatic conditions. Dr. Garrod was Physician Extraordinary to her late Majesty Queen Victoria, a Vice-President of the Royal College of Physicians of London, and in 1891 received the Moxon gold medal awarded by the College for research in clinical medicine. He was a Fellow of the Royal Society, and received the honour of knighthood in 1887. He was the author of many books and memoirs connected with the forms of disease to which his attention was chiefly devoted, but he had retired from practice for some time before the occurrence of his last and fatal illness, dying at the ripe age of 88 years.

LIEUT.-COLONEL MAITLAND, M.D.ED.

WE regret to announce the death of Lieut.-Col. J. Maitland, of the Indian Medical Service, retired, late Principal of and Professor of Surgery at the Madras Medical College, and Senior Surgeon at the Madras General Hospital. Colonel Maitland died at Bournemouth at the age of 55. He graduated at the University of Edinburgh in 1874, joined the Indian Medical Service in 1876, and was appointed to the General Hospital, Madras, and a Professor at the Medical College in 1882. He took the M.D. degree in 1888, and after filling various appointments in Madras and at the Medical College and General Hospital, was in 1896 appointed Professor of Surgery, and in 1903 Principal of the Medical College and Senior Medical Officer at the General Hospital. Lieut.-Col. Maitland was a honorary Fellow of Madras University, and was the author of "Elephantiasis and Allied Disorders," and of papers on "Filarial Disease," "Some of the Less Common Manifestations of Filariasis," etc.

I. HAWKER SOPER, M.R.C.S.ENG.

WE regret to record the death of Dr. I. Hawker Soper, of Plymouth, formerly of Blaina. Dr. Soper, who was in his 76th year, had been in failing health for some time, and on December 22nd he passed away as the result of senile decay. Dr. Soper from his early days was intended for the medical profession, and was a student at the old South Devon and East Cornwall Hospital. Having completed his studies, he went to Blaina, Monmouthshire, and started a practice which, by his skill and industry, proved to be a large and lucrative one. Fourteen years ago Dr. Soper retired from practice and removed to Plymouth to reside. Of an energetic and benevolent disposition, the deceased soon found scope for his activity, and he was especially interested in all movements for the benefit of the poor. His eldest daughter is the wife of Mr. Bramwell Booth, the chief of the staff of the Salvation Army.

GEORGE J. SEALY, M.R.C.S.ENG., L.S.A.

WE regret to record the death, under most tragic circumstances, of Dr. G. J. Sealy, a well-known medical man, residing at Oak Hill House, Weybridge, on the 24th ult. He was galloping on horseback by the side of the Thames, from Shepperton to Chertsey, a groom following, and was going at a good pace, when suddenly the bank gave way at the bend near the windmills. Both horse and rider were pitched into the river, which at this point is very deep. The deceased, who was booted and spurred, sank immediately, and the horse started to swim. The groom never saw Dr. Sealy again, the swift stream carrying him away. The horse swam to the bank. It is believed that the recent heavy floods have softened the earth embankment, and thus rendered it unsafe.

REVIEWS OF BOOKS.

OPERATIONS OF GENERAL PRACTICE. (a)

THE idea of this book is quite a good one, namely, to describe in detail those operations which may frequently be undertaken in general practice, in order that practitioners who but seldom resort to surgical measures may have encouragement to do so. The authors truly say "Most operative surgery is easy when the operator has mastered the technique of surgical cleanliness, and has some opportunity of practising the art." It is the facility with which most surgical operations may be performed, the kudos that attends success, and the proportionately high fees chargeable which determine most capable men who start in practice to do their own surgery. Unhappily when work is confined to a small circle, when the principle of averages has not the opportunity of operating, sooner or later he is apt to find that, even if he has escaped the odium of being "fond of the knife" and not being "much good at medicine," he is brought up by some untoward calamity, which in hospital practice has been put down as bad luck, but which may do him infinite damage in the neighbourhood. People expect deliberate operations to go without a hitch, and surgeons are paid on a scale which allow them, so to speak, to insure the risk of failure. It is a little amusing that the junior of the authors of this book, who appears to have just emerged from the house-surgeon stage, should join the seniors in sagacious reflections on the general practitioner, such as: "With the advance of medical and surgical knowledge a better educated and more highly skilled practitioner has come into existence," and again "the good work done in these (cottage hospitals) indicates that he should have further facilities to enable him to draw a line between his possibilities and his limitations." One cannot help remembering that many of these gentlemen who are thus encouraged were probably house-surgeons before the junior author was acquainted with the potentialities of stereoscopic vision. However, if we pass to the business of the book we can certainly congratulate the authors on the lucidity, completeness, and practical character of the descriptions, and also on the judiciousness of their choice of subjects. We notice much small and graphic detail which must be of great help to a man who is performing an operation alone for the first time, and who does not wish his unfamiliarity with detail to attract the notice of attendants. The point that calls most particularly for criticism is the little, or comparatively little, importance attached by the authors to local anæsthesia, especially with eucaine and adrenalin. To the general practitioner for whom this book is specially intended, the advantage of taking anæsthetist and anæsthetic in the waistcoat-pocket is extraordinary, and there are very few of the operations here mentioned that cannot be done under local anæsthesia. However, the practitioner who is acquainted with the blessings of local anæsthesia, and uses this volume to aid him in ideas and technique, may find his way happier and blither than it would have been even two years ago.

MINOR MEDICINE. (a)

THERE is no doubt that since the abandonment of the "apprenticeship" method of commencing medical education, neo-practitioners have to learn what practice is after qualification instead of before. The consequence is a very distressing bewilderment when confronted with the myriad ailments not falling into any particular category that patients complain of. The author has put together what may be described as "post-graduate notes" in order to assist young practitioners in their dilemma. The list comprises affections as alien to each other as bilious attacks and balanitis, sea-sickness and scabies, the removal of cutaneous stains and the treatment of dysuria—in fact, we are initiated into the mysteries of symptomatic therapeusis. The work is eminently practical, and its utility is enhanced by a liberal provision of prescriptions, which, after appearing in the text, are collected for facility of reference at the end, under their respective headings. There are useful hints as to diet in various functional disturbances and morbid states—altogether a very handy work of reference in dealing with the minor ailments of life.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT MEDICAL LITERATURE.

Ascites from Cirrhosis of the Liver treated by Operation.—Ketchen and Thomson (*The Practitioner*, December, 1907) discuss the very important question of the indication for this form of treatment of cirrhosis of the liver. The writers divide the cases of cirrhosis of the liver into two well marked clinical classes. The first class includes those cases in which ascites is an early symptom, which occurs before there are any signs of general poisoning of the system. The cases belonging to this class generally show marked improvement after being tapped. In the second class are cases in which the ascites is a late symptom, occurring when the general systemic disturbances are well marked, and in such cases if the fluid is withdrawn death frequently occurs before a second tapping becomes necessary. It is now generally recognised that the ascites in both classes of case is the result of peritonitis. The writers believe that in the first class of case this peritonitis is an entirely local condition, running coincidently with the changes in the liver but not dependent on them. The peritonitis and the cirrhosis both appear to be due to the same cause. In the second class of case the peritonitis appears to be due to a toxæmia which has resulted from the destruction of the liver cells and the consequent loss of the filtration function of the liver. Cases in the first class are as a rule greatly benefited by the operation of omentopexy, probably not so much on account of the anastomosis established between the portal and systemic veins as because of the increased arterial supply to the liver. The nutrition of the cells at the surface of the liver suffers from the obstruction to the hepatic arteries, and the new blood supply from the omentum to a certain extent counteracts this. In the second class of case operation does not delay, but rather favours, a fatal termination. For a clinical diagnosis between these two classes the writers rely on the general symptoms of the patient and the evidences for or against the presence of a general toxæmia. If the patient has been tapped several times successfully, his general condition remaining good, it is likely that an omentopexy will be beneficial. K.

The Medical Treatment of Gastric Ulcer.—Stockton (*Amer. Jour. of the Med. Sciences*, December, 1907), in an address delivered at the seventh triennial Congress of American Physicians and Surgeons, discusses this very important subject. He distinguishes two fairly well marked types of case: (1) that which as a rule starts in young chlorotic women, a type of case which is usually more common and which is usually acute. (2) The second type of case more usually occurs in elderly men, or at all events in men past middle life, and in its onset is usually chronic and in its course is more persistent. The difference in the history between these two types of case suggests a difference in their etiology, but the sameness in the processes enforces a belief that in most respects they are the same disease. Dr. Stockton has carefully examined both before and after gastroenterostomy the gastric contents of a patient who for years had been in the habit of swallowing knives, screws, nails and glass. He has found that though there were injuries to the gastric mucosa and some irritation, yet there was fair digestion of ordinary food, and injuries of the mucous membrane were rapidly recovered from. It has also been found that many serious cases of ulcer have occurred in stomachs having a gastric juice of very low acidity and feeble digestive power. These facts would point to the presence of some other factor in the causation of gastric ulcer than merely local injury and excessively acid gastric juice. This factor he finds in the lowering of the internal cellular resistance in some focus or foci of the gastric mucosa. The suggested explanation of these foci is that there is a want in the antibody in the cells of the mucosa which should normally antagonise the digestive ferments of the stomach, this want being further attributed to a tropho-neurosis similar to that causing herpes facialis. From this explanation Stockton draws his indications for treatment, which he believes should in the first instance be medical. A calm nervous system in a well-conditioned body is the state to be aimed at, and this state is to be attained by different means in different cases. One patient does better with complete gastric rest and abstinence from food for some days, while another does best with the rather full feeding recommended by Lenhartz. In all cases the treatment must be continued for a considerable period after apparent cure, making careful study of the stools for the presence of occult blood. From the medical point of view Stockton considers that the function of surgery in gastric ulcer is to relieve secondary results rather than to cure the ulcer itself. K.

Paralysis Agitans.—Berkely (*New York Med. Journal*, November 23) considers the therapeutical results from the administration of the parathyroid gland to cases of paralysis agitans. He draws attention to the fact that a properly identified gland must be used. Nothing much in the way of favourable results can be hoped for except from relatively small doses continued through a long period of time. These patients are nervously unstable, which fact must be borne in mind in drawing conclusions. Berkely has notes of 30 cases with the following results: Two patients declined to continue treatment; two have not been heard from; five denied benefit; three showed temporary improvement only; 18 were progressively benefited during the entire period of treatment. D.

The Influence of Food on Tuberculosis.—Weigert (*Berlin Klin. Woch.*, October, 1907) claims that clinical and physiological observations and experiments show that there is a direct connection between the water content of the organism and its power of resistance against infection. The greater the fluid content the less is the resisting power of the tissues. In animals fed on carbohydrates the fluid content is at its maximum. It is a demonstrable fact that different forms of food affect the composition of the organism. The author, working on these lines, fed five pigs on fat, and five others on carbohydrates. The animals were then infected with tuberculosis, and it was found that the fat-fed pigs reacted in a much lesser degree to the infection than those fed on carbohydrates. Weigert suggests that, taking these results into consideration, the diet in human tuberculosis should be largely fat and should contain little carbohydrate food. D.

Delirium and Delirious States.—Swift (*Boston Med. and Surg. Journal*, November, 1907) considers the fundamental attribute of most deliriums a disturbance of consciousness, using that term to imply the condition of mind under which external stimuli produce cerebral changes of some sort, of which the subject immediately becomes cognisant, and which he is accustomed to regard as ideas, feelings, etc. He discusses fever delirium, delirium tremens, the cause of delirium, the differential diagnosis, the treatment and prognosis. In regard to treatment, a continuous warm bath, he states, is generally preferable to soporific drugs as a quieting measure. The patient is kept in a bath at from 92 to 95 F., until restlessness subsides, when he is put to bed. This method of treatment is particularly useful in delirium tremens, but must be used with caution in asthenic conditions. Heart stimulants, such as alcohol, strychnine, and digitalis, may be indicated, but in alcohol delirium or in the presence of polyneuritis alcohol must be avoided. In threatened delirium tremens during enforced abstinence, Swift is inclined to side with those who believe that small doses of alcohol are beneficial. It may be distinctly beneficial in senile delirium. Regular nourishment—by the tube, if necessary, is important. The prognosis depends on the presence or absence of an underlying incurable cause. D.

Diagnosis of Cancer of the Stomach.—Brown (*Lancet-Clinic, Cincinnati*, November, 1907) reports two carefully reasoned cases which emphasise the fact that, with all the advantage of laboratory findings as an aid or a check to careful clinical examinations, stomach conditions are by no means easy of diagnosis. In the first case, the age, history, epigastric pain, absence of hydrochloric and presence of lactic acid, evacuation of blood with a stomach tube, and apparent constriction of the cardiac orifice, progressive emaciation and cachexia, apparent hour-glass constriction on X-ray examination, and secondary progressive anæmia, notwithstanding the absence of tumour and coffee-ground vomit, pointed clearly to gastric carcinoma; while the autopsy disclosed pulmonary tuberculosis, acute miliary tuberculosis, pulmonary œdema, atrophic gastritis, chronic interstitial nephritis, and ulcerated tuberculous enteritis. In the second case, all the symptoms, the blood findings, the occult blood in the stools, seemed to point to pernicious anæmia; and the absence of any detectable tumour, coupled with the presence of free hydrochloric acid in the gastric contents, did not divert the consideration to gastric carcinoma. Yet at autopsy a scirrhous carcinoma was found on the posterior wall. Brown concludes by pointing out that, valuable as the laboratory findings are as aids or checks, they are not infallible, and cannot replace a careful anamnesis and systematic physical examination. D.

New Local Anæsthetic.—Thibault (*Journal Arkansas Med. Soc.*, Little Rock, September, 1907) speaks highly of the value of quinine infiltration as a local anæsthetic. He describes an interesting series of personal experiments on himself, which arose out of his use of quinine hypodermically for the cure of malaria. After making several injections with first a 4 and then a 2 per cent. solution of quinine and urea bichlorid, he answered the objections that the results were an instance of pressure anæsthesia by infiltrating spots on each side halfway between the umbilicus and ensiform process, two inches from the median line, on the right side using the 2 per cent. quinine and urea injection, and on the left side a normal saline solution. At the end of five minutes there was no sensation in either place, but while sensation quickly returned over the area infiltrated with the saline solution, the anæsthesia on the right side was tested at intervals of one hour for six hours without producing any pain. He has since tried all the soluble salts of quinine, and found them to be good local anæsthetics when injected in 1.5 per cent. or stronger solution. He has used this local anæsthetic in amputation of a finger, removal of a large fatty tumour half a pound in weight, incision of a large carbuncle, divulsion of the sphincter for the removal of a fish-bone. He concludes:—(1) It is efficient in 1 to 2 per cent. solutions; (2) healing is as rapid as with any other local anæsthetic; (3) it is safer than any other local anæsthetic of any like equal efficiency; (4) solutions can be kept in stock and boiled repeatedly without deteriorating; (5) it is efficient when applied in 15 to 20 per cent. solutions to raw surfaces on cotton pledgets; (6) the anæsthesia lasts from one to six hours. D.

Great ravages are being caused at Mecca, Medina, and Yambo by the cholera outbreak. The deaths number over a hundred daily.

Medical News in Brief.

The Public Health Acts Amendment Act, 1907.

The Local Government Board has sent round a circular to the councils of municipal boroughs and urban and rural districts on the subject of the Public Health Acts Amendment Act, 1907, which comes into force on January 1st. The object of the Act is to enable sanitary authorities outside London to obtain when requisite, and without incurring the trouble and expense involved in promoting Bills for local Acts, various additional powers which are based upon provisions in local Acts passed in recent Sessions of Parliament.

The Board's purpose in the circular is to draw attention more particularly to those provisions of the Act which prescribe the procedure for applying enactments in it to any particular locality, and which are contained in section 3. Under that section the Board are empowered, upon the application of a local authority, by Order to be published in such manner as the Board direct, to declare any part or any section of the Act to be in force in the district of the authority, or where they are a rural district council in any contributory place in their district, and also to declare any enactments in any local Act which appear to the Board to contain provisions similar to or inconsistent with any such part or section to be no longer in force in that district or contributory place (section 3 (1)). The Board will be ready to give attention to applications under the Act, but they think that such applications should not be made unless the local authority are satisfied that the powers sought are really needed.

Coventry Medical Men and the Dispensary.

Dr. Pickup and Dr. Orton have written a letter in reply to Dr. McVeagh on the profession and the local dispensary, and on the position of Dr. McVeagh in relation to his colleagues in the division. Drs. Pickup and Orton say, *inter alia*: "Dr. McVeagh's bonhommie and genial presence, as well as his mature years, have long endeared him to the medical profession in Coventry, and it was a matter of great regret that circumstances compelled the members to place him in the same category as the three medical men who filled the vacancies in the Provident Dispensary. At various times and at various meetings Dr. McVeagh has expressed his dissatisfaction at the management of the dispensary as strongly as any of his late colleagues, and he frequently stated that he was willing to leave the dispensary could he afford to do so. Efforts were made by the division to raise a fund to compensate him for any financial loss he might sustain, but as nothing less than a guarantee of £200 a year for life would satisfy him, such efforts proved abortive."

Death under Chloroform.

Mr. Troutbeck held an inquest at Lambeth, on December 24th, on the body of Edward Edwin Boyd, a milk-carrier, who died under chloroform in St. Thomas's Hospital. The widow said that an operation was performed on her husband in the hospital on the 16th. She went to the hospital on Sunday, and had only spoken to her husband for three minutes when she was told to leave the bedside. He had told her that the doctors were going "to do him a bit of good." The doctors were waiting at the foot of the bed when she was sent away. About two hours later, when she was still in the hospital, she heard of his death. "I blame the doctors for his death," she said. "He was too weak to stand it. He was too near death at the time. I think he was slowly murdered." Dr. Nightingale, the house surgeon, said there was no chance of saving his life unless an operation was performed. Had he not undergone an operation he would have died that day, but an operation gave him a chance of life. Dr. Ronald E. Todd, who administered the anæsthetic, said he gave chloroform and ether. About 15 minutes after the patient had been under its influence he became very feeble, and the usual means of restoration were applied, but without success. Dr. Trevor, the pathologist of St. George's Hospital, agreed that the second operation was the only chance of saving the man's life. The Coroner said that Boyd himself was quite aware of the situation in which he was placed, and consented to an operation. He excused the wife's language, because she was under great emotion. A verdict in accordance with the medical evidence was returned, and the jury concurred with the Coroner's remarks.

Death under an Anæsthetic at Bridgwater.

THE Deputy-Coroner for the borough held an inquest, on December 23rd, concerning the death of Eliza Ellen Coles, æt. 36, whose death had taken place at the hospital. The evidence showed that the deceased suffered from internal pains, and under medical advice was removed to the hospital, where on Sunday an anæsthetic was administered in the presence of the whole medical staff for the purpose of making an examination of the patient, but just before the stage of unconsciousness the deceased suddenly changed colour, which implied that something was radically wrong. The deceased had also stopped breathing, and the medical staff tried artificial respiration and other means for quite an hour to restore animation, but without avail. Dr. Penrose Williams deposed to having made a post-mortem examination, which showed that one of the heart muscles was atrophied, and that was sufficient to cause the deceased to go off under an anæsthetic. The cause of death was heart failure, due to the administration of the anæsthetic, in conjunction with the nervousness inseparable from the circumstances of undergoing the same. The jury returned a verdict in accordance with the medical evidence.

The Notification of Births Act.

AMONG the legislative measures passed during the last Session of Parliament, the Notification of Births Act will come into operation to-day (New Year's Day). The Act was framed with a view to decreasing the waste of infant life, especially in the larger centres of population. By its provisions the Medical Officer of Health has to be informed within 36 hours of the birth of a child, so that he may, where necessary, advise as to the rearing and nursing of the infant. It is not a compulsory measure, but several Metropolitan parishes have already made preparations to use its powers to the full. Our Glasgow correspondent also refers fully in another column to the Act as it affects the profession in Scotland.

A Coroner's Predicament.

A SINGULAR incident occurred at an inquest held at Lewisham on December 27th, on the body of a child named Cutler, aged three months. Dr. John Wood said he had made a post-mortem examination, but had failed to discover the cause of death. The Deputy-Coroner said, as Dr. Wood could not find any evidence as to the cause of death, it would be necessary to call in another medical witness. A messenger was despatched for Dr. F. S. Toogood, who later on reported that he had made a post-mortem examination, and had seen the child's mother. Having regard to the history of the case, he was of opinion that the child had died of convulsions, although the mother had not seen it, and that death was due to this cause, followed by failure of the heart's action. A verdict of "Death from natural causes" was then returned.

Medical Men's Claim.

A CURIOUS claim was brought before His Honour Judge Granger, at the Redruth County Court. Drs. J. H. Tonking and William Blackwood, of Camborne, sued Miss Ada E. Roach for £38 12s.

Counsel for the plaintiffs said he understood the defendant and her father had been in communication with His Honour on the matter. Miss Roach, who was formerly a governess at Camborne, was taken ill and removed to the Redruth hospital and operated upon for a perforated stomach. It was an urgent case, and Drs. Tonking and Blackwood, assisted by other surgeons, performed the operation, which was a most difficult one, and fortunately successful. Some 70 visits were paid to Miss Roach, and the account was for £38 12s.—20 guineas for the operation and the balance for the visits, etc. Defendant's father had paid everybody else, but had refused to pay the plaintiffs, holding that the fees were excessive. In his letter, to which Dr. Tonking took strong exception, on account of the manner in which the claim was disputed, Mr. Roach admitted that a moral tribute of praise was due.

Dr. Blackwood bore out the advocate's statement. The operation was performed on May 7th. Mr. Roach, who was a naval pensioner, living at Plymouth, endeavoured to get a Plymouth doctor down for the operation, but the last train had left Plymouth, and a motor could not cross Torpoint. If a Plymouth doctor had performed the operation, he would have charged 30 guineas and expenses.

His Honour agreed with that view, and remarked that the operation was successful, and no doubt very well done. He gave judgment for Drs. Tonking and Blackwood for the full amount claimed, with costs.

Royal Academy of Ireland.

THE following resolution, passed by the Council of the Royal Irish Academy, has been forwarded to the Secretary of the Royal Commission on Vivisection, now sitting:—

"The Council, fully recognising the vital importance of experimental investigations carried out on living animals, believes it is desirable that licences to perform such experiments should continue to be granted to qualified workers.

"The Council believes that the restrictions at present regulating the granting of licences are adequate.

"The Council would desire to see licences granted by the Home Secretary on the recommendation of:—

"(1) The head of any of the Universities of Great Britain and Ireland.

"(2) The head of any of the medical licensing corporations.

"(3) The head of any of the chartered scientific societies.

"(4) The head of any of the veterinary colleges."

The Norwegian "Smoked Process" in Dietetics.

WE have received from the Stavanger Preserving Company, the well-known inventors of the "Norwegian Smoked Process," some samples of tomato purée and of "Crossed Fish" sardines. The goods are neatly packed in tins, and the sardines are preserved in the finest virgin olive oil. The delicacies prepared by this firm are well worth a trial by those who are unacquainted with them, and we recommend them to make the experiment.

New Tabloids.

MESSRS. BURROUGHS, WELLCOME AND CO., from their ever-active laboratories, are always furnishing fresh weapons against disease or old weapons in new guise. Three of their latest preparations are capsules of calcium iodo-ricinoleate (each containing 3 grains), capsules of terebene (each containing 5 minims), and capsules of sandalwood oil (each containing 5 minims). All are of the "Tabloid" brand, and, we need hardly add, of the same superior class and finish which have long characterised the drugs bearing that *cachet*.

MARTINDALE'S TUBERCULIN TEST (CALMETTE).

A GREAT deal of attention has been drawn to the remarkable observations of Calmette. It was shown by that authority that where tuberculosis, either medical or surgical, existed in man, its presence could be detected by the ophthalmo-reaction obtained by dropping tuberculin in liquid form into the eye. The usefulness of so simple and speedy a test to the medical practitioner is obvious. Messrs. Martindale supply the tuberculin in a convenient tube, the end of which is broken off, and a drop or two of tuberculin placed on the conjunctiva. If there be no tuberculosis there is no reaction. If, on the other hand, tuberculosis be present, the lower conjunctiva and caruncle commence to redden within three hours, and the reaction attains its maximum between the 6th and the 13th hours. The test is safe, rapid, and apparently free from fallacies. A full account is given by Mr. Sydney Stephenson in the *Ophthalmoscope* for September and October, 1907.

NOTICES TO CORRESPONDENTS, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Dr. A. H.—We would be glad to have a fuller report of the case before deciding.

Massage.—We fear we cannot trespass on the domain of the nursing-home proprietor unless a *prima facie* case of improper conduct is made out. This, we understand, was not so in the present instance?

THE COMPLETE CATECHIST.

The Quack Doctor's Catechism.

(For the instruction of unqualified medical practitioners in those arts by which alone success is to be attained in this irregular branch of the profession.)

Question: Who are you?

Answer: A quack doctor.

Q.: What is a quack doctor?

A.: An individual of very limited medical knowledge, but of unlimited assurance, whose boast it is to be able to cure all manner of diseases—particularly those which are pronounced to be incurable by the qualified Faculty.

Q.: Have you many unique and sovereign remedies?

A.: Yes. I have as many of them as there are diseases known to Medical Science.

Q.: Are they all different?

A.: All.

Q.: Wherein do they differ?

A.: Mostly in the colouring matter with which I tint the water in which they are mixed.

Q.: Are these various unique remedies expensive?

A.: Absolutely—yes. Relatively—no.

Q.: Of what class of persons do your patients chiefly consist?

A.: Of the poor, the ignorant, and the uneducated.

Q.: How do such persons manage to pay the high prices you demand of them?

A.: They pinch and save and deny themselves the very necessaries of existence in order to do so.

Q.: Do you ever feel sorry for these poor creatures who, relying on your promises of cure, thus pinch and scrape to save up money for the treatment?

A.: I never feel in the least sorry for them. It would be ridiculous, on my part, to do anything of the kind.

Q.: Why so?

A.: Because no wise man is ever sorry for any simpleton whose simplicity puts golden guineas into his (the wise man's) pocket.

Q.: Do patients who have little or nothing the matter with them write to you thanking you for the marvellous good you have done them, and bearing eloquent testimony to your skill and capacity?

A.: They do.

Q.: What use do you make of these letters?

A.: I print them in my advertisements, and exploit them for all they are worth.

Q.: Do patients, on the other hand, ever write to you complaining that your remedies have proved absolutely useless, and demanding the return of their money?

A.: Frequently.

Q.: What use do you make of these letters?

A.: I give them to the caretaker to light my office fire with.

—*Truth*.

Medical Economist.—Your letter is unavoidably held over till our next.

Edinburgh Student.—In reply to your queries, you will find Moorhead's "Surface Anatomy" and Buchanan's "Manual of Anatomy" the best for your purpose. The latter differs materially from the work referred to by you, in that it is systematic and practical, including Embryology.

THE *STANDARD* AND MEDICAL BUTCHERY.

Under the above heading we commented in our issue for December 18th upon a most discreditable advertisement which was appearing in a prominent position in the *Standard* newspaper. The announcement was that of a certain quack, who styled himself "Professor," and was of the most insulting character to the medical profession. We expressed regret that an advertisement of such an outrageous nature should have found admission into the columns of a hitherto respectably conducted newspaper, and it affords us satisfaction to know that it has now been stopped.

Dr. Arany (Karlsbad).—Your paper is marked for early insertion.

THE VALUE OF WIRELESS TELEGRAPHY.

The value of the wireless system of telegraphy was shown at Dover on Sunday last, when a passenger on the mail packet "Marie Henriette," crossing from Ostend, put his shoulder joint out of place, and was in great pain. A wireless message was sent from the vessel to Ostend, and thence to Dover, for a doctor to meet the boat, and on arrival at the Admiralty Pier the passenger was promptly attended to.

Dr. L. G.—Certainly, with pleasure

Mr. C. J. H. and **Dr. W. S. L.**—Letters greatly appreciated.

Appointments.

Aubrey, R., L.R.C.P. and S.Edin., District Medical Officer of the Bath Union.

Cassidy, M. A., M.A., M.B., B.C.Cantab., M.R.C.P.Lond., M.R.C.S.Eng., Resident Assistant Physician at St. Thomas's Hospital.

Cotton, R. H., M.R.C.S., L.R.C.P.Lond., Second Resident Assistant Medical Officer at the Infirmary for Medical Relief Districts 1 to 4 of the Parish of Lambeth.

Harris, Dudley Raymond, L.R.C.P.Lond., M.R.C.S., *pro tem* Medical Officer for the Falmouth Workhouse.

Hutt, C. W., M.R.C.S., L.R.C.P.Lond., Senior Resident Assistant Medical Officer, Chorlton Union Workhouse.

Peace, P. C., M.R.C.S., L.R.C.P.Lond., Resident Medical Officer at North Evington Workhouse, Leicester.

Titterton, J. T., M.B., C.M.Edin., District Medical Officer of the St. Germans Union.

Vacancies.

Sheffield University.—Demonstrator in Anatomy. Salary, £150 per annum. Applications to W. M. Gibbons, Registrar.

Cardiff Infirmary.—Medical Man required to take Charge of the Electrical Department, which includes X-Rays and Finsen Light. Salary, £150 per annum. Applications to Leonard D. Rea, Secretary and General Superintendent.

Sussex County Hospital, Brighton.—Third House Surgeon. Salary, £50 per annum, with board and residence in the Hospital, with washing. Applications to the Secretary.

The Middlesex Hospital, W.—Resident Medical Officer. Salary, £200 per annum, with residence and board in the Hospital. Applications to F. Clare Melhado, Secretary-Superintendent.

North-Eastern Hospital for Children, Hackney Road, Bethnal Green, E.—House Physician and Two House Surgeons. Salary at the rate of £60 per annum, with board, residence, and laundry. Applications to the Secretary. (See Advert.)

Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Assistant Medical Officer for the New Crossley Sanatorium. Salary, £100 per annum, with board, apartments, and laundry. Applications to C. W. Hunt, Secretary, Hardman Street, Deansgate, Manchester.

Monkwearmouth and Southwick Hospital, Sunderland.—House Surgeon. Salary, £100 per annum, with board, lodging, and washing. Applications to the Secretary.

Chesterfield and North Derbyshire Hospital.—Senior House Surgeon. Salary, £120 per year, with board, apartments, and laundress. Applications to the Secretary.

Taunton Union.—Medical Officer. Salary, £75 per annum, together with 10s. for each case of Midwifery. Applications to W. F. B. Dawe, Clerk.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—A Casualty Medical Officer. Salary, £200 per annum, with lunch. Applications to Stewart Johnson, Secretary. (See Advert.)

Nottingham Children's Hospital.—Lady House Surgeon. Salary, £80 per annum, with board, residence, and washing. Applications to A. F. Kirby, Secretary, Albion Chambers, King Street, Nottingham.

Borough of Burslem.—Education Committee.—Lady Doctor. Salary, £150 per annum. Applications to A. T. Sheldon, Secretary, Education Offices, Burslem.

Births.

Sibley.—On Dec. 27th, at The Mansions, 70, Duke Street, Grosvenor Square, London, the wife of W. Knowsley Sibley, M.A., M.D., of a daughter.

Gutch.—On Dec. 27th, at 30, Fonnereau Road, Ipswich, the wife of John Gutch, M.D., B.C.Cantab., of a daughter

Marriages.

Pasmore—Screech.—On Dec. 21st, at Holy Trinity Church, Sloane Square, Edwin Stephen Pasmore, M.D., M.R.C.P., Medical Superintendent, Croydon Mental Hospital, Warlingham, Surrey, to Gertrude Eva, second daughter of the late John Screech, Esq., of Yelverton.

Thomson—Finlay.—On Dec. 24th, at Kohat, Captain Alexander Guthrie Thomson, 58th Rifles (Frontier Force), Indian Army, to Annie Wilhelmina, second daughter of Dr. W. A. Finlay, Trinity, Edinburgh.

Colbourne—Wilbey.—On Dec. 21st, at St. Mark's, Hamilton Terrace, London, Harold Brehmer, eldest son of Louis Colbourne, M.D., Beckenham (late of Buenos Ayres), to Blanche Kirsten, youngest daughter of Jules Edward Wilbey, of Maidenhead.

Deaths

Garrod.—On Dec. 28th, at 10, Harley Street, London, Sir Alfred B. Garrod, M.D., F.R.C.P., F.R.S., Physician Extraordinary to her late Majesty Queen Victoria, in his 89th year.

Respiratory Inflammations.

There are many reasons why Angier's Emulsion is so extensively employed in bronchitis and the various inflammatory affections of the respiratory organs incidental to the winter months. The first and most potent of these reasons is the universally attested clinical fact that the remedy quickly relieves these conditions. Equally true is it that the Emulsion exerts its curative influence in both the acute and chronic forms of bronchitis. Cough is checked, bronchial irritation allayed, and expectoration facilitated. No other remedy has such sedative demulcent and lubricating effects, while its stimulating influence on nutrition overcomes the oft-present element of systemic depression. It is no exaggeration to state that Angier's Emulsion is not only the simplest but likewise the best treatment for acute and chronic inflammatory affections of the respiratory organs.

(Petroleum with Hypophosphites).

THE ANGIER CHEMICAL CO., Ltd., 32 Snow Hill, LONDON, E.C.

FORMAMINT

An Excellent Antiseptic and Prophylactic in Diseases of the Throat and Mouth

EFFICIENT SUBSTITUTE FOR GARGLES

COMPOSITION: Vide Article on "Oral Sepsis" in *The Lancet*, Oct. 20th, 1906.

"A chemical combination of Formic Aldehyde and Lactose put up in the form of a compressed tablet."

"A non-toxic and trustworthy antiseptic in all ages, differing entirely from simple solutions of formic aldehyde in nature and in action being much more powerful, devoid of any irritating properties, and which on solution by the saliva sets free that disinfectant in a nascent form."

INDICATIONS: in all conditions of **SEPTIC SORE THROAT**, as **TONSILLITIS**—Simple, Septic and Follicular—**DIPHTHERIA, SCARLET FEVER, MEASLES, THRUSH**, etc.

"In ten cases of **Diphtheria** the treatment by Formamint Tablets was employed as a substitute for local treatment by disinfectant gargles, and in some of the milder cases anti-toxin was dispensed with. In all cases the improvement was rapid."—(*British Medical Journal*, January 13th, 1906, Epitome, page 8.)

"A proved antiseptic and bactericide, non-toxic in action, far more efficient than gargles or mouth washes, particularly suitable for children and entails no pain, and its portability is of considerable convenience."—*Medical Magazine*, March, 1907).

Samples & Literature on Application to

A·WULFING & Co, 83, Upper Thames St, LONDON, E.C.

"I like the idea of the Two Irons in Hemaboloids"

was the comment of a physician to whom this preparation was presented, and this peculiarity is worthy of special note.

Each Tablespoonful of Hemaboloids contains an amount of iron equal to that contained in 20 minims (1.33 c. c.) Tr. Ferri Chlor.

1. The larger part of the iron in Hemaboloids exists in organic combination with the necleo-proteids obtained from vegetables rich in iron.
2. This vegetable food-iron is reinforced or "ferrated" with a less resistant organic iron compound, in order to more readily neutralize the sulphur-bearing compounds in the bowel, thus preventing the destruction and permitting the absorption of the food-iron in Hemaboloids, as well as that contributed by the daily food supply.

Dose: One Tablespoonful 3 or 4 times a day, Children in proportion.

Thus the Premier Claret (the Chateau Lafite) of a class **usually sold at about 84/0** per dozen **is now offered by us at less than 2/6 per bottle.**

An allowance of
6d. per doz. on from 12 doz. to 29 doz., and
1/0 " " 30 doz. and upwards will be made.

Never before was such an opportunity offered to Connoisseurs to acquire a Wine of this famous growth and of such quality and with complete guarantee as to authenticity at so low a price. Admirers of fine Claret should not miss this opportunity, which is not likely to occur again.

The Barons de Rothschild, the Proprietors of the famous Chateau Lafite, did not, during the greater part of the 'eighties, permit any bottling at the Chateau; but the superior 1890 Vintage was bottled for them with full brand on corks, and held in a special cellar, small quantities only having been parted with.

The Wine was bottled in greatest perfection, is in splendid condition, showing its great breed and style, possessing fine colour, beautiful bouquet, great elegance, and matured fruitiness. It is very soft and mellow, and a most superior dinner and dessert Claret of best style.

In sympathy with the movement to assist the undoubted revival in taste for high-class Claret, the holders have been prevailed upon to sell, and **we have purchased the whole existing quantity** of this excellent Wine at a most reasonable price and have been placed in a position to offer it at the above nominal and most moderate rates, far below its true value and less than half the usual selling price of this growth and quality.

Vol. CXXXVI. WEDNESDAY, JAN. 8, 1908. No. 2.

NOTES AND COMMENTS.

Goose-oil. THE curious dietaries and remedies which poor and ignorant mothers provide for their infants are the subject of many comments at health lectures and the like, and they go a long way to show the necessity for the schools for mothers which are being established some centres. We do not, however, remember to have seen mentioned before a delicacy which a mother spoke to using at Wolverhampton the other day, namely, rancid goose-oil. In our ignorance we must acknowledge to not knowing the beneficial results which are supposed to spring from the internal employment of this uncommon article of materia medica, but it seems that it was kept in the home of the woman in question, and when her three-day-old infant had a "wheezing on the chest" she proceeded to seek relief for him by the exhibition of the oil. The desired effect not being produced, half a teaspoonful of gruel was administered, but the infant still ailed, and whether from inherent delicacy or from the mixture of the goose-oil and gruel, or from a combination of these adverse circumstances, it eventually gave up the ghost. The mother had been attended in her confinement by an old woman who was not even a certificated midwife, but it did not come out whether she advocated the administration, or whether the mother relied on her own intuitive therapeutic promptings. Goose-grease is a well-known country panacea for external injuries, such as bruises, abrasions, and sprains, and in its way it is certainly as efficient as most of the four-and-sixpenny boxes of ointment that are advertised, but the idea that goose-oil turned rancid is good for any internal complaint, especially of a newly-born infant, is staggering. The question arises whether supersitition darker than this existed in the darkest period of the Middle Ages, and whether compulsory primary education, far from curing popular beliefs and traditions, has not merely turned them into other and perhaps more harmful channels.

Guinea-pig Barometers. OUR contemporary, the *Indian Medical Gazette*, always affords interesting and instructive reading for homesters, and in the December number we find an ingenious paper by Captain R. D. Saigol, of the Indian Medical Service, on "Rats and Guinea-Pigs as Plague Barometers *versus* Rat Destruction." Captain Saigol reviews the various methods aimed at the pestiferous rodent, from the keeping of tame cats to feeding him with bacteria-infected food, and the writer points out how little impression any of these measures can really make on the infinite number of rats in India. He justly observes that if plague itself, which is to rats the most fatal of all diseases, will not exterminate them, it is not very hopeful that any other poison or disease will. He then suggests that rat-proof houses should be built and cleanliness observed, and that in such houses cages of guinea-pigs or rats should be kept. He argues that if a plague-infected rat gained admission to the house, its fleas (*pulex cheopis*) would prefer, on quitting their host, to go to the juicy guinea-pigs or succulent rat rather than to the comparatively insipid human. Not only would the guinea-pig, or caged rat, act as a flea-filter, but if it were infected in turn its death would be an indication of threatened plague and preventive steps could be taken. Moreover, the course the plague was taking at any time could be easily followed by the deaths of the domesticated rodents. The plan likes us much. We can picture paterfamilias tapping the "barometer" before he goes out, and discussing rat "snaps" and guinea-pig "waves" with his neighbour in the railway-carriage; but, from a youthful experience of white mice which were not kept for hygienic indications, nor under particularly hygienic conditions, we can only be thankful that we of temperate climes have not got to provide each of our rooms with a cage of rats. The remedy is a drastic one.

Whitaker manque. THE infallibility proverbially associated with the name of Cocker is as nothing to the exact, stupendous omniscience which we moderns attach to the name of Whitaker. Indeed, if the compiler of that annual were to receive ten per cent. on the bets settled by reference to his pages, he would probably be in a position to give up the task of compilation altogether. But even Homer nods, and Whitaker, having stepped on to the slippery slope of medical custom, has come, slightly, to grief. A medical man was suing a recalcitrant patient, and the defendant alleged that the charge was excessive. "Whitaker" was brought forth as his authority, and the scale of doctor's fees there given quoted as authoritative. We do not profess to understand how the judge admitted "Whitaker" as evidence at all, except on the principle that if one wishes to err it is better to err in good company; however, the evidence was listened to, and part of the statement read out ran as follows: "All engaged in the profession are supposed to be equal in point of skill, and therefore entitled to charge alike, the tariff depending chiefly upon the residence of doctor and patient." Now the scale given is really a very fair one, and it is a pity that it was not left without comment, as it would give people a guide as to approximately what to expect a medical man in the ordinary way to charge. But to say that all men are "entitled to charge alike" means either that no one is allowed to charge more than his neighbour, or that the "sixpenny doctor" may charge a hundred and fifty guineas for bisecting a duchess's cook because she lives in Belgravia. As a matter of fact, the former is obviously untrue, and the latter is ridiculous. Medical charges are fixed by custom; districts vary enormously, and the fees received by eminent practitioners outside London are much smaller than those acceptable to West End practitioners of no greater skill.

Noblesse oblige.

As showing, however, how the traditions of the profession appeal to foreigners, it is interesting to note that the German High Court held that it was illegal for the medical practitioners to band themselves together and establish a definite code of fees for professional services. The reason given for this weird decision was that the Court held that medical practitioners are actuated by a desire to serve their fellows and not to seek their own interests, and therefore, they do not expect to be paid in full for their work. It is comforting to know that doctors are so highly thought of in Germany and that their generosity is so proverbial, but in a matter-of-fact community such a decision will only mean that a great many unscrupulous scoundrels will never adequately requite their medical attendant for his services. The German Court was good enough to add that doctors stood above the level of men of business pursuits, and the establishment of a fixed fee would lower their dignity. But high position, even if accorded, is a poor recompense for an empty stomach, and we agree with the philosopher who observed that, however undignified it might be to do certain things, there was nothing more undignified than poverty. It is quite true that medical men can never hope to obtain a full recompense for their work, but they like to decide for themselves who shall be the objects of their charity. It is one thing to act on the principle of *noblesse oblige*, and another meekly to allow oneself to be swindled.

LEADING ARTICLES.

THE PUBLIC HEALTH ACTS AMENDMENT ACT.

The new Public Health Acts Amendment Act, which now becomes operative, marks an important advance in national health administration. The general effect may be described as equalising to a great extent the powers of rural and urban sanitary authorities throughout the United Kingdom with those hitherto enjoyed by the London Council as regards the health of the community. Part I. of the new Act authorises the extension to all parts of the United Kingdom, exclusive of London, all or any parts or sections, by an order of the local Government Board or the Secretary of State. In future, therefore, the Central Board may declare any section or sections of the Act to be operative wherever they may deem such a step desirable. It is worthy of careful note that appeals to Quarter Sessions may be made by persons aggrieved by any order under the Act. Part II. affects streets and buildings. A deposit of plans can be declared by a local body to be inoperative if the work be not commenced within a period of three years from the date of the deposit. Powers are given for regulating the width, access and other conditions of streets and roads. As regards urgent repairs to private streets to obviate danger to passengers, the local authority may require the owners to execute the same forthwith. Under Section 20 owners may be required to make good damage to any public road or footway due to excavations or the works on their private property. Part III. deals with sanitary provisions, and adds to the list of circumstances constituting a nuisance. A nuisance is legally defined as that which destroys the whole comfort of life of the public. The third part of the Act refers to rain-water pipes and closets, expenses, payments for works for the common benefit of two or more buildings belonging to different owners, and the removal of urinals. The local authority can require the owner to provide and maintain urinals in any inn, public-house, refreshment-house, or place of entertainment. If a medical officer has grounds for distrusting the drains of any building, he may apply the smoke or coloured-water test, and the owner can be required to remedy the defect. If local authorities are required to remove trade refuse (other than sludge), they must do so, charging a reasonable sum, to be settled, if necessary, by a court of summary jurisdiction. There is given a power for local bodies to provide ambulances. Part IV. deals with infectious diseases. It forbids a person knowing that he is suffering from such to engage in any occupation which risks the spread thereof. Infected clothes may not be sent to a laundry, and filthy articles in dwelling-houses may be purified or destroyed. Dairymen can be compelled to state their sources of supply. Children suffering from infectious diseases may not be sent to school without a permit from the local medical officer, and the principal of a school where such disease has been must send a list of the scholars to the local authority. Another provision, of importance chiefly in Ireland and in the Irish quarters of English and Scotch towns is the forbidding of "wakes" over the bodies of persons who have died of infectious disease. It is to be hoped that this provision will not bring the Act into conflict with deeply-rooted tradition and prejudice, not to mention the religious feelings of a number of his Majesty's subjects. The Act makes the owner and every guest liable who take part in a "wake" over the body of a person suffering from infectious disease. Part V. introduces common lodging-house legislation. A court of summary jurisdiction may cancel the registration of a common lodging-house keeper on a first offence against any provision of the Public Health Acts, and not merely on a third conviction, as under Section 88 of the Public Health Acts, 1875. Part VI. of the Act of 1907 deals with recreation grounds. The rest of the ten sections deals with police, traffic, registration of servants, and other matters of less direct interest to medical men. On the whole, this may be regarded as the most comprehensive and detailed extension of public health that has taken place for some time.

THE LOCAL GOVERNMENT BOARD AND STRAIT JACKETS.

For many years past we have from time to time urged the necessity for some greater measure of central control of our Poor-law system, but so far the long-wished-for day of reform has not arrived. The appearance of a fresh scandal now and then disturbs the public conscience, and the lay Press is provided with a nine-days' wonder, after which things settle down into the old groove. A typical occurrence of the kind has been recently investigated by Mr. Arthur Downes, the Local Government Board Inspector. The subsequent report, couched in his usual lucid and able style, furnishes some suggestive reading. The subject of the inquiry was the death of a Dane, aged 39, who died in the observation ward of the Hampstead Workhouse, after having been there for seventeen hours, seven of which were spent in a strait jacket, without having been seen by a medical man. Read in the light of this bald statement the incident takes one back to the worst days of the old *régime* of Bumbledom. A man is brought into a workhouse in a state of maniacal excitement: there is no padded room, and he is consigned to the tender mercies and skilled judgment of an attendant, who claps him forthwith into a strait jacket. The medical officer is either summoned late or is otherwise engaged; anyway, the upshot of this sordid story is that the unfortunate man dies without medical advice. It is needless to point out in the columns of a medical journal that prompt medical attention is absolutely necessary in such cases, and that the majority recover more or less completely under appropriate treatment. That part of the matter is not emphasised in the condensed copy of the Inspector's report at hand. It is enough to know that such an occurrence is possible under what is commonly described as the humane modern conditions of the Poor-law. Unfortunately there is no reason to flatter ourselves that the incident is isolated and exceptional. Years ago we dwelt on deaths in padded rooms in London workhouses, and we asked for a full investigation of this point by the Local Government Board. We have little doubt that were such returns available the public would be provided with a sensational exposure of no common order. What is possible in the largest and wealthiest city in the world, however, is much more likely to happen in other parts of the United Kingdom, notably amongst the poorer and less densely populated districts. In the Hampstead case the report can hardly be regarded as adequate, at any rate, by those who are anxiously awaiting the coming of a new spirit into Poor-law control. The attendant is mildly censured for having failed to summon a medical officer, and his subsequent conduct is to be reported upon in three months' time. The master is blamed for not having seen the man after admission. It is further urged that all officials concerned should be informed as to the official regulations laid down for the treatment of lunatics. In our opinion, the Local Government Board cannot absolve itself by a perfunctory report of this kind. We presume that the main defects of the Hampstead Workhouse Infirmary, including the non-resident medical officer, the absence of a padded room, and the system for the reception and control of lunatics has long been within the knowledge of the Board's inspectors. We presume, further, that repeated official reports have been submitted to headquarters drawing attention to these defects. If this has not been done the inpectors have failed in their duty; if this has been done and steps have not been taken to secure an immediate remedy, then the responsibility lies with the Board. What is the use of a central authority which does not enforce the provision of elementary accommodation in workhouses and workhouse infirmaries for all medical emergencies? Of late years much has been heard about the coming Poor-law reform. Here is a field in which there is no need to wait for a future; the work is ready to the hand of the labourer. If the Local Government Board is unable to insist upon proper accommodation for acute mental cases in Poor-law institutions, then the Board itself must be in no less urgent need of reform than the workhouse system, whose duty it is to guide, govern, and control in such a way as to render it an efficient State service.

CURRENT TOPICS.

The State Regulation of Laundries and Notification of Births.

AMONG the laws that have come into force with the New Year is the Factory and Workshops Act of 1907, which was introduced by the Home Secretary in the House of Commons on behalf of the Government. By the provisions of this Act all laundries in which persons are employed for wages, and which are carried on for purposes of trade, are brought under the Factory Act, 1901, as regards regulating the hours of employment of women and young children in such establishments. The implicit—if not the explicit—effect of the Act is to bring laundries connected with charitable institutions under the control of Government inspection. In order to meet objections raised in certain quarters a special provision is made, by section 5, sub-section 2. par. d, whereby the private interrogation of inmates of reformatories is excluded, except on the authority of the Secretary of State. Another law that becomes operative is the Notification of Births Act, devised with a view of reducing the present high rate of infantile mortality. In districts where the Act is adopted, notice of birth must be given in writing to the medical officer of health within six hours, either by the father (when residing in the house at the time), or of the person in attendance upon the mother, under a penalty of 20s., recoverable on a summary conviction. The legislation applies to the birth of any child which has issued forth from its mother after the expiration of the twenty-eighth week of pregnancy, whether alive or dead. So far as London is concerned, the medical officer of every metropolitan borough is directed to send a weekly list of notifications of birth to the County Council. One serious defect in the Act is the omission to provide for payment of the services of the medical attendant when called upon to sign the certificate of birth, while, at the same time, he is subject to pains and penalties for non-complance in the matter. The graver objections we have discussed.

The Progress of Cremation.

CREMATION, like many other desirable reforms, moves but slowly in the estimation of the public. The reasons for this tardiness of advance are mainly sentimental, but, in spite of all objections, there is little doubt that the movement in favour of this form of burial is slowly but surely gaining ground. Several of the large cities have availed themselves of the powers conferred by the Cremation Act to erect crematoria. One noteworthy fact is the attitude of the clergy, which nowadays in some, if not in all of the churches, is favourable to this most ancient of rites. At the opening of the Birmingham crematorium, a few years since, Bishop Knox said that in spite of sentimental objections cremation was not only preferable from a sanitary point of view but was also a most reverent and decent treatment of the bodies of the dead, and one that was in entire accordance with Christian belief. At a recent meeting of the Manchester Crematorium Company it was reported that the number of cremations during the past year had reached 104, the largest hitherto in any one year, making a total since the opening of the crematorium of 1,119. From a sanitary point of view the arguments in favour of the disposal of dead bodies by fire burial are simply overwhelming. The contingency of the destruction thereby of the evidence of possible poisoning was carefully guarded against in the Cremation Act, 1902, which demands a statutory declaration and an independant confirmatory medical certificate.

Chloroform and Burglary.

Notwithstanding the length of time chloroform has been before the British public, there appears to be still a good deal of popular misunderstanding as to its particular properties. The most common error is probably that of the novelist and playwright, who attributes an instantaneous action to chloroform, somewhat akin to the rapid intoxication familiar on the opera stage. From time to time chloroform figures in the accounts of burglaries with the persistency and eke the elusiveness of the famous sea-serpent which is the pride of journalistic mythology. The latest romantic story of the kind comes from a village near Pontypool, where a young Welsh servant-girl was found one morning stark naked and tied to a bedstead. Her statement was that she awoke to find standing at her bedside two men who made her show them where the silver was kept under threat of death. At this stage of the proceedings she was too terrified to scream out. After the silver was looted, one of the burglars took the girl back to the bedroom, stripped her, and tied her to the bedpost. It was then that the chloroform appeared for the first time in the condensed drama, for the burglar, possibly by that time convinced that there was a danger of the girl becoming so startled as to scream and thereby alarm the household, placed a handkerchief saturated with the narcotic drug over her mouth, and departed. Most of the silver appears to have been found in the back yard. On general grounds it may be pretty safely asserted that the use of chloroform in burglary is hardly yet within the range of practical politics, a belief which is rather confirmed than otherwise by the internal evidence of the Pontypool incident.

The Central Midwives' Board and the Coombe Hospital.

The somewhat remarkable statement emanating from the Central Midwives' Board, which we published in our last issue, relative to the training of midwives at the Coombe Hospital, reminds us very strongly of the reports of certain police-court proceedings, which occurred recently. A man was prosecuted for driving a motor-car to the public danger, and also for attempting to bribe the policeman who stopped him on the road. He was convicted, and fined sixty pounds. A short time afterwards another man was prosecuted for driving a horse and trap to the public danger, and also for attempting to bribe the policeman who stopped him on the road. He was convicted, and fined forty shillings. There is no one who will try to justify bribery, but, even so, there are few who will consider that bribery committed in connection with a motor-car is thirty times a worse offence than is bribery committed in connection with a horse-drawn vehicle. Similarly, there is no one who will justify the signing of incorrect certificates, but there are few, in Ireland, at any rate, who will not be led by the rather non-judicial statement issued by the Central Midwives' Board, to think that perhaps a similar offence occurring in England would not have been punished in quite a similar manner. The Central Midwives' Board has itself resorted to so many quibbles with the object of placing the semi-illiterate "handy-woman" on the roll of trained midwives, and has so persistently tried to exclude the highly-trained Irish maternity nurses, that it is no wonder if it is has made those with whom it comes in contact casual and inaccurate.

Football Mortality.

There are few genuine sports which are entirely free from bodily risk. Even golf, which is probably the safest of all, has its victims, though they are not many. The most engrossing of all sports, such as fox-hunting, mountain-climbing, and big-game shooting, undoubtedly depend for much of their fascination on the element of risk associated with them. That a sport has its dangerous moments, therefore, does not necessarily condemn it, but, nevertheless, there are limits to the risks which it is justifiable to undergo. In these countries we are accustomed to regard football as a comparatively safe game, and we allow our boys to play it without let or hindrance. We hear of a broken collar-bone or an inflamed knee now and then, but permanent injuries and fatal accidents are very rare. In America, however, things are far otherwise, and the game of football stands for something quite different from what we understand by the name. A couple of years ago the high mortality from football injuries in the States attracted so much attention that, by the force of public opinion, the rules underwent certain modifications. The result was at the time gratifying, as the numbers dropped from 22 deaths and 96 serious injuries in 1905, to 10 deaths and 63 serious injuries in the following year. During the 1907 season which has just ceased—for the American football season lasts only a few weeks of the beginning of winter—there were 14 deaths and 58 serious injuries. It would appear, therefore, as if the promised improvement had failed to appear, and as if the changes in the laws had not been sufficiently radical. The problem has, therefore, yet to be solved. Our experience in these countries shows how, under strict rules, football may be played with safety, and there is no reason why an equally strict code of rules should not render it safe in America. Otherwise, it is likely that the game will have to be totally prohibited in schools and colleges.

Medical Lectures to the Public.

It is only within the past few years, and as a part of the modern sanitary campaign, that it has come to be recognised as permissible for medical men to address themselves to the public in the form of lectures on medical subjects. There is no doubt, however, that instruction given in this way may do good public service, and if controlled by certain definite limitations, we can see no objection to medical men taking their natural place as leaders of the public on matters relating to health. A usual limit imposed by the good sense of the profession is that detailed references to curative methods are to be excluded. The anti-tuberculosis movement in Ireland has given us so far the best example in these countries of instruction being systematically given to the public on sanitary affairs by members of the profession. It is true that some annoyance has been caused by the fact that a few of the lecturers took little notice of the limit we have mentioned as usual, and made perhaps somewhat unnecessary references to their own therapeutic successes, but, on the whole, the courses of lectures, which have now been running for some months, have been unexceptionable in tone, and productive of good results. In America an interesting step has just been taken by the medical faculty of the University of Harvard. During the next four months, on Saturday nights and Sunday afternoons, a member of the faculty will address the public on some medical subject. The subjects cover a wide field, but they seem admirably chosen, and, for the most part, unhackneyed. Among others are "The modern crusade against typhoid fever," "The sick child," "Rational infant-feeding," "The relation of the hospital to the community," "Mental hygiene and the prevention of insanity," and "The development and maintenance of good teeth." These are subjects on which the public requires instruction, and we shall watch eagerly to see whether this venture of Harvard will prove a success.

The Prevention of Sleeping Sickness.

It is to hoped that the recommendation made by the International Conference on Sleeping Sickness, held in London last June, will not be allowed to drop out of sight, but will become the basis of some international action. Most of the members were not invested with full powers to allow of their signing a definitive convention, and accordingly the Conference was adjourned to November 1st. Lord Fitzmaurice, who presided, said that the disease had decimated the Congo, had worked no less havoc in Uganda, and had appeared elsewhere. Accounts were given of the measures to combat the disease which had been taken by the various Governments. It was recommended that a central bureau should be established in London with branches in each of the countries represented. It was also suggested that efforts should be made to prevent natives from passing from contaminated districts. Cutting down the jungle has had good effects in driving away the tsetse fly, which inhabits the edges of lakes and rivers where there is forest. The fitting of screens to European houses and steamers and the wearing of veils and gloves were also recommended.

Medical Opinion and Vivisection.

Although there is no difference of opinion in the medical profession as to the necessity for experiments on animals in the course of research, yet it is quite possible that this unanimity may not be sufficiently impressed on the Royal Commission at present inquiring into the subject. We are glad to note that the Royal Academy of Medicine in Ireland has taken the step of putting into the form of resolutions the opinions of its members as regards experiments on animals, and of forwarding these resolutions to the secretary of the Commission. We publish them in another column, and it will be seen that the Academy thinks that the present regulations are sufficiently strict, while it urges that licences should be more easily obtainable than at present. They should be granted, it is suggested, on the recommendation of the heads of universities, medical and veterinary colleges, and chartered scientific societies. The changes urged by the Academy are sensible and practicable, and we hope that other responsible medical societies will also consider the question, and forward their views to the Royal Commission.

PERSONAL.

The Companionship of the Order of the Indian Empire has been conferred on Major J. N. Macleod, I.M.S.

Major Robert Charles Macwatt, I.M.S., has been made the recipient of the Kaisar-i-Hind Medal (First Class).

Mr. Malcolm Morris, F.R.C.S.Ed., has been appointed by the King a Knight Commander of the Royal Victorian Order.

Public testimonials were presented to Dr. George Petrie Hay, of Forres, on his retirement from the practice of his profession at the end of last year.

Sir James Crichton-Browne will take the chair at the inaugural meeting of the Society for the Destruction of Vermin, to be held at the Hotel Metropole on Friday next.

Sir John Tweedy will take the chair at the second annual dinner of past and present students of the Royal London Ophthalmic Hospital at the Trocadero on January 29th, at 8 p.m.

The Khedive has conferred the Grand Cordon of the Medjidieh on Sir Horace Pinching, K.C.M.G., who recently retired from the post of Director-General of the Public Health Service of Egypt.

Dr. J. Agar Matson has been appointed by the Lord Lieutenant to be a member of the Board of Governors of the Westmorland Lock Hospital, in the room of Dr. J. Magee Finny, who has resigned.

Dr. Laveran, who was recently awarded the Nobel Prize for Medicine, intends, we understand, to present a portion of the £7,600 he received to the Pasteur Institute, in order to encourage the work of scientific research.

Dr. W. D. Stoney Johnstone, M.B., Ch.B., Edin., and Dr. Victor M'Allister, M.B., B.Ch., B.A.O., R.U.I., ex-House Surgeon Mater Misericordiæ Hospital, Dublin, have been appointed Assistants to the Master of the Coombe Hospital.

Dr. George Turner, Medical Officer of Health for the Transvaal, will shortly retire under the Civil Service age limit, and will return to England. He is said to have saved Cape Colony something like six millions sterling stamping out rinderpest.

A Clinical Lecture
ON
PSORIASIS: ITS CLINICAL AND MICROSCOPICAL CHARACTERS, DIAGNOSIS AND TREATMENT.

By ARTHUR WHITFIELD, M.D., F.R.C.P.,

Professor of Dermatology in King's College, Physician for Skin Diseases to King's College and to the Great Northern Central Hospitals.

Gentlemen,—I have chosen the subject of Psoriasis for my lecture this afternoon because it is in this country so common a disease that it has a great practical importance, and it not infrequently presents difficulties in diagnosis and treatment.

The time at my disposal will hardly be sufficient for a very detailed description of the clinical characteristics, which, after all, are only too familiar to us all, but I hope to be able to pick out certain points which may be of interest and use to you.

Psoriasis is perhaps the most uniform of all the skin eruptions, if one studies the evolution of the process. It is true that certain differences are at first sight very striking, but on close examination one finds that these differences are only produced by the preponderance of one or more characteristics which are always present.

The earliest lesion of psoriasis is a scaly papule, and one may say that for practical purposes the lesion of psoriasis always remains a scaly papule. Whether the redness which is always present precedes the scaliness or *vice versa* is a point upon which I should not like to offer any opinion, never having seen either of these two features alone. The first characteristic to which I will draw your attention is the fact that this primary papule undergoes in most cases what we may call an essential extension. By this I mean that the actual lesion increases in size by gradual extension of its border, and without necessarily the aggregation of fresh lesions. By keeping this fact always in your mind you will at once remove many of the difficulties of distinguishing this eruption from that of other dry and scaly skin diseases.

Next I wish to point out to you the characteristics of the scale. This is, as I have already stated, present when the essential lesion is first noticed, and consists of several layers of apparently dry horny layer, and may be either silvery in its undisturbed condition, or it may be yellowish at first, and only take on its silvery characters when roughed up by means of scratching. It is always hard and gives a marked sense of resistance to the finger when felt. As the lesion extends peripherally new scales are formed beneath the original one, so that the centre of the scale is thicker than the edge, a condition well seen in the photograph I now show you of a case of acute psoriasis in a boy of about twelve years. You will also notice on close examination that the edge of the scale is apt to be less firmly attached than the centre, so that if you wish to detach the scale it is best to work from the periphery towards the centre. This is in sharp contradistinction to what occurs in tinea circinata and in pityriasis rosea, diseases which are often confounded with psoriasis, but in which the scale is always frayed out towards the centre, so that in attempting to remove them one naturally works from the centre towards the periphery. If one starts then from the periphery with a blade of a pair of scissors and attempts to lift the scale of a psoriasis papule, one finds that it is easy to lift off a coherent mass of scales thicker in the middle than at the edge, and after removing this mass one finds exposed a glossy surface showing on examination with a hand lens, minute red points shining through it. These points are, as I shall show you, the apices of dilated and congested papillæ. If now you pass the finger over the lesion thus denuded of its scale you will find that it imparts scarcely any sense of resistance to the finger, and if felt at all gives the impression of a succulent œdema rather than of new formation, an important point, as upon it rests the differential diagnosis between psoriasis and a scaly syphilide. I show you here two photomicrographs to demonstrate these points, and you will see that in comparing the histology of psoriasis with that of syphilis that in the former there is a comparatively small accumulation of cells limited to the papillary body, whereas in syphilis even as in this case of the most superficial variety, there is a well marked accumulation of cells round the vessels extending to a considerable depth in the corium.

I may also point out to you in this place what has been considered by some a characteristic feature of psoriasis, namely, the presence in the scale of small collections of leucocytes, the so-called "dry abscess" of psoriasis. For the rest of the histology I need not bother you with many details, but there are one or two points to which I may allude. These are the changes in the papillæ which have overgrown and become distended at their apices so that they have become club-shaped, extending much nearer to the horny layer than usual, and accounting for the red points which I have already mentioned; the diminution, or more commonly complete absence of the granular layer and the retention of the flat nucleus in the cells of the horny layer.

If after satisfying yourself that there is no "infiltration" or accumulation of cells in the skin by palpating the denuded lesion, you proceed to gently scratch the shining surface, you will find after a few seconds that you produce minute pin-point hæmorrhages which are derived from these individual congested papillæ. It is important that the scratching be very gentle, as if roughly done, the hæmorrhage may be produced in a number of eruptions and the diagnostic significance is lost.

So much, then, for the essential characteristics of the psoriasis lesion. We may now seek to inquire what may be the further development of it, and what peculiarities it may show. We have already ascertained that peripheral extension is usual, and we may now see that this may occur to form a large more or less circular sheet of eruption, or it may, by the occurrence of central resolution, produce large rings and polycyclical figures of which I show you two well-marked instances. In some cases the scale may be comparatively slight, so that it is transparent, and scarcely noticeable until roughed up by scratching, and the base may be very red and actively inflammatory; in others the scale may reach enormous dimensions, being heaped up to a conical mass strongly suggestive of rupia. To this form has been given a special name—"Psoriasis rupioides." It is very easily differentiated from rupia by lifting off the scale as there is no ulcer beneath it.

As regards the localisation of psoriasis, let me caution you against placing too great reliance on distribution for the purpose of diagnosis. In one of the gyrate cases which I have already shown you the chief incidence of the attack fell on the flexor surfaces, and I now show you two scalpy syphilides which both occurred only on the extensor surfaces. In my experience those cases of syphilis which most closely counterfeit psoriasis are the very ones in which the rash affects the extensor surfaces. In acute psoriasis the distribution is apt to be generalised, and it very frequently attacks both the back and front of the trunk in much the same manner as does the early syphilitic eruption. It is an open question as to how psoriasis begins. Some authorities believe that there is usually one initial lesion which is followed by a general outbreak, while others hold that the first outbreak is generalised at once. I have traced the course of a good many cases, and in my experience the latter view is the correct one.

There are two special localisations to which I should like further to allude, namely, the palmar and plantar surfaces and the scalp. Palmar and plantar psoriasis is a term which is still, unfortunately, often applied to designate a scaly syphilide, and indeed any scaly eruption of the palms and soles. I may point out that in acute generalised psoriasis the palms and soles are not so very rarely affected, and therefore palmar and plantar psoriasis should be reserved for these cases, for a disease is either psoriasis or syphilis. It is never both. I am quite aware that the diagnosis may be difficult, and perhaps impossible, but we shall certainly not learn by cloaking our ignorance under the term syphilitic psoriasis. The head is interesting from another point of view, namely, the difficulty of distinguishing between psoriasis and pityriasis capitis or as it is sometimes termed, seborrhœa sicca. Both are dry scaly diseases, and both are characterised by peripheral extension. So great is the clinical difficulty that there are still great authorities who maintain that the eruptions are different phases of the same disease. If, however, one will take the trouble to examine the scales in a rough manner by a microscopical examination which takes at the outside five minutes this difficulty at once disappears. The psoriasis scale, even when taken from the scalp, shows no organisms present at all, whereas the scale from pityriasis is crowded with examples of the bottle bacillus and other organisms as you see in this slide.

In the diagnosis of psoriasis from ringworm, the microscopic examination of a scale in potash is, of course, the ultimate test, but the exactness of the circular outline, the almost invariable presence of minute papulo-vesicles around the margin of the ring, and the arrangement of the scales with their loose border pointing inwards, to which I have already referred, will usually be enough to allow you to recognise a circinate ringworm on the glabrous skin, and the additional presence of broken hairs will aid you in scalp cases.

As regards the etiology and pathology of psoriasis, I have little to say. We know that the disease is commoner in cool climates, in the winter months; that it has a distinct tendency to run in families; and that it is occasionally associated with a joint trouble resembling, if not identical with, sub-acute rheumatoid arthritis. One or two doubtful instances of infection have been reported, but the disease is certainly not very contagious. Beyond this we know nothing, and all theories as to the causation are mere speculation with which I shall not bother you.

We may now turn to the practical point of treatment.

As regards internal treatment, the drug with the most general reputation is, of course, arsenic. Now, among the experts opinion appears to be considerably divided, some regarding it as of great, though uncertain value, while others do not hold it in high esteem.

My own opinion is that it is often of extreme value, though I admit that one cannot tell in which cases it is likely to succeed. It is generally said that in acute outbreaks it is liable to aggravate the disease, and this I quite admit to be the case in some instances, but I have found that most cases that are even moderately acute and irritable do well with it, and therefore if I have a patient whom I can take into my confidence, I often give it in irritable cases. It is quite easy to knock it off if it increases the symptoms. The great point is that one should give it in full doses—up to fifteen minims of the liquor three times a day, such a dose being naturally reached by gradual steps. If you like, you may use atoxyl in doses of a half to one grain three times a day, but this is a drug which occasionally causes a good deal of colic and purging, so that you must be cautious in your use of it. Another drug highly recommended by some is salicin in full doses. After trying it in very many cases, both consecutively taken and selected as acute, I have never seen any action at all.

Thyroid extract will occasionally cause the eruption to melt away in an almost magical manner, but here again high doses are required, and one can never say which is the case in which it is likely to be of benefit. Lastly, potassium iodide does undoubtedly cause the disappearance of the rash in certain cases, and it is not always necessary to give it in the heroic doses which some recommend.

As to the question of bathing in psoriasis, it may be said that in almost all cases it is beneficial. In irritable cases a prolonged soaking in an alkaline bath (washing soda, ¼ lb. to a thirty gallon bath) often relieves the itching in a very gratifying way, and of course helps in the removal of the scales. In indolent cases one may also assist the removal by scrubbing with soft soap.

After all, we must admit that the local treatment is more uniformly successful, and the most efficacious drugs in their order of efficiency are probably the following:—Chrysarobin, tar, pyrogallol, resorcin, mercury, salicylic and carbolic acids. A nice cleanly way of using chrysarobin is to paint on a coat of a 10 per cent. solution in chloroform, and after it has dried cover it in with waterproof strapping. Or one may use it dissolved in collodion, but this stains more and is less efficient. Tar may usefully be incorporated with the highly superfatted soft soap sold under the name of " Mollin," as it is then more easily washed off, or in mild cases the liquor picis carbonis, either used neat or diluted, may be painted on. One can nearly always safely begin with a 10 per cent. solution.

For the scalp a useful formula is half a drachm of resorcin in an ounce of white precipitate ointment. This must be made with paraffin, or it decomposes at once, and in any case it does not keep well, so that it should be ordered in small amounts.

In the extremely irritable cases, it is often recommended that the treatment at first should be limited to soothing lotions such as the following Glycerini, glycerini plumbi subacetatis aa, ℥ j., aq. ad oj., and this is certainly fairly efficient in removing the scales, but I have usually found that the alkaline bath, followed by a calomel (3 per cent.) ointment is more efficacious.

Lastly, there are the cases where one or more patches prove resistant to almost all forms of treatment, although there does not seem much tendency to the appearance of new ones. In these the X-rays will often be found of signal service. It is best to give a nearly maximum dose once every fortnight, though if the apparatus for accurate measurement is not at hand, very small doses may be given four or five times a week. It is of the utmost importance that the dosage be either carefully measured, or limited to the smallest amount at each sitting, as I have seen the most deplorable effects from over-exposure and burning in connection with this disease.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Andrew Wylie, M.D., C.M., Assistant Surgeon, Central London Throat, Nose and Ear Hospital. Subject : " Tubercular Laryngitis."*

ORIGINAL PAPERS.

THE PROPOSED CHANGES IN THE

TEACHING OF PRACTICAL MIDWIFERY. (a)

BY SIR WILLIAM SMYLY, M.D.,

Ex-President of the Royal College of Physicians of Ireland.

I HAVE been invited to open a discussion to-night upon the recommendations of the General Medical Council with regard to education in midwifery; and especially as regards the applicability of those recommendations to the teaching of midwifery in Ireland.

In the first place, then, I would call your attention to the circumstances which have led up to this action on the part of the General Medical Council. The commencement was, without doubt, the discovery by Semmelweis of the true nature of puerperal fever, by Pasteur of its causation, and by Lord Lister of how it could be prevented; in consequence of which this scourge has been practically banished from our lying-in hospitals. It was naturally anticipated that a similar result would follow in private practice, but this anticipation has so far not been realised. Hegar was, I think, the first to call attention to this lamented fact, and he attributed it to the increased number of operations. So that what had been gained by antiseptics had been lost through meddlesome interference. In these countries Dr. Boxall showed that, from the returns of the Registrar-General, it appeared that not only had there been no improvement in regard to the mortality from septic infection in childbed, but actually the reverse. The numerous papers and voluminous correspondence in medical and other journals, which this statement provoked, produced a profound impression in England, the outcome of which has been the Midwives Act, and the efforts of the General Medical Council to improve the education of students in midwifery, which we have now to discuss. Unfortunately, in this country the matter has aroused but little interest, and those who have shown any interest in it have been so divided in opinion that Ireland has been excluded from the Midwives Act, to our great injury and loss. Having failed, then, to secure any improvement with regard to midwives, I most sincerely hope that we shall not be found equally remiss with regard to our medical practitioners, for, as Dr. Boxall has shown, the state of affairs with regard to puerperal mortality is worse with us than it is in England.

The recommendations of the General Medical Council must be considered in two aspects: first, from the educational side, and secondly, as regards examination. From both these aspects the Council has been hampered by trying to reconcile what is desirable with what is possible. In England the opportunities for the teaching of practical midwifery are of the most meagre description. In London, for example, there is only one lying-in hospital open to medical students, and even there, where the course is strictly limited to three months, a very small proportion of the students can be provided for; and when every available source of practical instruction has been exhausted, a large body of the students still remain unprovided for. This is evident in the replies sent by the teaching bodies to the enquiries of the General Medical Council. Middlesex Hospital, for example, clearly states "that the difficulties in carrying out the recommendation that students should previously have attended the indoor practice of a lying-in hospital or the lying-in wards of a general hospital are at the present time insuperable." University College, in reply to the question, " Is it, in your opinion, possible at the present time to arrange for every student to attend for one month the practice of a lying-in hospital or the lying-in wards of a general hospital before attending or conducting twenty labours?" answered "No," and added: "The committee further thinks that a month is a longer period of time than is actually necessary to devote to attendance in a lying-in hospital or ward, and that a fortnight would be sufficient." Under such circumstances the Medical Council found itself forced to make very moderate demands upon students with regard to the practical study of midwifery, and their modest recommendations are, in my opinion, not only the best that could be recommended in England, but would seem to be too good to be carried out in practice there.

But when we consider their application to this country, with its great lying-in hospitals, with their ample supply of material, and large and efficient staffs of highly-trained teachers, it would seem to be an absurd retrogression to adopt any of the recommendations of the General Medical Council, for I have not the slightest hesitation in stating that six months' attendance on the practice of one of our large maternity hospitals is far more likely to produce experienced obstetric practitioners than would the adoption of any of the recommendations of the General Medical Council.

How is it, then, that, in spite of superior advantages, our results, as pointed out by Dr. Boxall, are so bad? I cannot here refer to the handy woman, but must confine my remarks to our medical students; and, in so far as the fault can be brought home to them, I fear it is the old difficulty with regard to a horse which has been brought to the water. Our ancestors asserted that this difficulty was insurmountable, and that we could not make him drink. But surely, in the twentieth century, that is not so, and the difficulty could be overcome either by forcing the fluid down his throat, or by developing a thirst that would compel him to drink of his own accord. And similarly with our medical students; we can either compel them to attend a certain number of patients or demonstrations, or we can arouse in them a desire to study practical midwifery. The former is the method at present in vogue; we compel the student to attend a certain number of confinements, a few of which he personally conducts, and that is all. Now, in considering the practical value of this method, let us imagine for a moment its adoption in the practical teaching of medicine or surgery. Supposing, for example, that the only practical work in these departments consisted in the examination of a score of people, the majority of whom were in perfect health; what would be the result as regards the returns of the Registrar-General when these gentlemen entered upon practice? With regard to obstetric practice, we have in this country ample provision for supplying skilled practitioners, and if the result is otherwise, it must be because they do not avail themselves of those opportunities. In fact, they seem to have no appetite for such study.

(a) An Address delivered before the Obstetrical Section of the Royal Academy of Medicine in Ireland, introductory to a general discussion on the subject, see page 43.

This brings me to the second method—the creation, namely, of a desire to study practical obstetrics and gynæcology. To the student, the all-important thing is to pass his examinations; to the ambitious to pass with distinction, but to every man, to pass. And he has a right to believe that his course of study and examination has been so planned and arranged for him that by following it he will find himself at the end in the best position to ensure success in his professional life. Now, what is that position, so far as it is indicated by the examinations in practical clinical work? It is that the diseases of the eye are the all-important group. In all others, excepting obstetrics of less account, and that of no practical importance whatever, a theoretical knowledge of midwifery is of course required, but, so far as practical work is concerned, he might, so far as his examination goes, have ignored it altogether.

Now I think that in this respect the recommendations of the General Medical Council are deserving of the highest praise, and I hope will be carried into practice. They advise that a genuine clinical and practical examination should be instituted by all qualifying bodies.

Well, now, what are we going to reply to these suggestions? As to the value of a practical clinical examination, no one can have a second opinion; but as to the possibility of carrying it out, there is ample room for discussion. There are certain inherent difficulties which have to be surmounted. I say have to be surmounted, because I earnestly beseech of you, now that an opportunity has been afforded, such as we have never had before, to improve the practical teaching of midwifery and gynæcology, not to turn your backs upon it and think it a thing impossible. It has been done in Edinburgh, where they have more students and less material than we have in Dublin. Can we not do what they have done? Those who are responsible for the conjoint examinations of our Royal Colleges have asked for suggestions. I can myself give them two, and I daresay, and hope, that better ones may be brought forward to-night, but my suggestions are these:—

1. If it is thought desirable that every student should have a practical examination in midwifery and gynæcology—for, observe that the Council does not suggest the former only—then by all means let us agree and try to carry it out; there would be no lack of material. But the chief objection I have to this plan is a want of proportion. Why should every student be examined upon one organ, be it the uterus or the eye, and not on all? If every student is to have a practical clinical examination upon the female pelvic organs, why should not the same rule hold good with regard to those of the male? If this is to be the rule, then should he not in every case be examined practically upon the diseases of the brain, of the spinal cord and nerves, the heart and vascular system, the respiratory, the digestive, the lymphatic, urinary systems, muscles, bones, and everything else? This is a *reductio ad absurdum*, but to my mind the absurdity lies in the present arrangement, where every student is examined upon the eye and its diseases, and none of them upon the female pelvic organs. Can anybody tell me why every student is examined upon the eye?

2. My second suggestion, which I think is the more reasonable and practicable, is that the female pelvic organs, with their varying physiological and pathological conditions, should be placed on the same level as other organs, and that a student should feel that, as regards practical work, his knowledge of them will be as useful in passing his examinations as would be a similar knowledge of the other organs of the body, and that he should be as liable—but not more so—to a practical examination upon one as another. At present men are examined on two or more medical and surgical cases; would there be any great difficulty in a certain number of candidates being selected by ballot to be examined clinically on one obstetric or gynæcological case, instead of one of the medical or surgical, and in some cases to substitute these subjects for ophthalmology? But these are only suggestions of detail; the all-important point is, are we to have a clinical examination, or are we to continue in the old groove which has resulted in discredit to our profession and disaster to lying-in women?

DIFFICULTIES ENCOUNTERED IN THE DIAGNOSIS OF CHEST DISEASE.

By JOHN HAY, M.D., M.R.C.P.Lond.,

Assistant Physician Liverpool Royal Infirmary; late Physician to the Stanley Hospital and to the Hospital for Consumption and Diseases of the Chest.

The following cases of disease of the chest have come under my care during the last two years, and exemplify a few of the difficulties not uncommonly met with in the diagnosis of abnormal conditions within the chest wall. The morbid conditions of the chest present in these four patients, and to which I shall refer in detail, were:—(1) actinomycosis; (2) sarcoma of the lung and mediastinum; (3) concealed empyema; and (4) pulmonary syphilis.

Case I.—Actinomycosis of the lung simulating pulmonary tuberculosis; embolic pyæmia; death. Girl, æt. 16. She came as an out-patient to the Chest Hospital on September 2nd, 1905, suffering from dyspnœa, cough and anæmia. Dr. Owen, who was then stipendiary medical officer, saw her, and made a diagnosis of pulmonary tuberculosis. She looked ill, and suffered from some cough, with expectoration. The cough was not severe, nor was the sputum large in amount. She had been ailing for six months, and had steadily lost weight. Her appetite was good, and her bowels regular. One noticeable feature in her condition was a pulse-rate of 160 per minute. On her next visit I carefully examined her. She was markedly anæmic, very short of breath, and was bothered with a rather troublesome, ineffectual and painless cough. Her heart was beating quite regularly at 170 to the minute. The heart was dilated, and there was a systolic murmur at the base.

On examining the lungs, I found some impairment of percussion note over the apices of the right upper and lower lobes. The breath sounds were altered, and, anteriorly, medium-sized râles were audible at the apex. The rest of the chest seemed to be normal. I agreed with Dr. Owen that the girl was suffering from consumption affecting the apices of the right upper and lower lobes, and that the tachycardia and tachypnœa were the result of a profound toxæmia. My advice to the mother was to put the girl to bed and to call in some medical man.

On October 19th I again saw the girl, on this occasion with Dr. Loughrey. She was propped up in bed, very pale and restless, suffering from marked dyspnœa which tended to occur in paroxysms. Her pulse-rate was still about 160. On examining her chest, I found the physical signs much as before; the local condition had apparently not altered. There was, however, one remarkable change in the appearance of the patient. Numerous small subcutaneous swellings were scattered here and there over the body; some of these had broken down and were discharging pus and blood. The edges of the openings were bluish red and indolent in appearance. There was a swelling situated over the spinous process of the seventh cervical vertebra, and many others on the hands, arms and legs. The left knee-joint contained fluid, and pus was oozing out from under the nails of some of the fingers and toes. A small collection of pus was situated on the tip of the nose. The ordinary signs of inflammation were absent. At first it flashed through my mind that this was a case of tubercular pyæmia, but something about the character of the edges of the openings suggested that the case was one of actinomycosis, and on carefully examining the pus I concluded that this suspicion was justifiable. Later in the day I examined the pus microscopically, and demonstrated the ray fungus with the club-shaped bodies at the circumference. On carefully questioning the parents, I found that the patient had been in the habit of eating large quantities of raw oatmeal and sugar, and I suppose that she had become infected in this way, for there is abundance of evidence to show that the parasite grows on grain, more especially, however, on barley.

CASE II.—Sarcoma, originating in the root of the lung, involving the left bronchus, encircling the aorta, paralysing the left vocal chord, infiltrating the left auricle; death by rupture of the heart. Man, æt. 29, complained of shortness of breath and cough. Family history good. His work, that of a marine engineer, was not very heavy. He did not admit to syphilitic infection or to excess in alcohol. For four months he had been afflicted with a troublesome cough. Latterly the expectoration had been profuse, and for two weeks before admission stained with blood. He had recently lost a stone in weight. There was no history of sweating, and his appetite was good. Pain in his left side gave him much trouble, and there was in addition slight pain at the base of the right lung.

He was admitted to the "Chest" Hospital, and examination revealed the following physical signs: impaired movement of the left side of the chest, with diminution of breath sounds, vocal fremitus, and vocal resonance; very slight impairment of note over the same area, but fairly well-defined dulness towards the base. Numerous râles were audible, more especially at the left base. The sputum was largely composed of mucus. It was frothy, viscid, tenacious, and bloodstained. It did not contain any tubercle bacilli. His cough was hoarse, husky, and rather lacking in explosive qualities. On examining the larynx, the left vocal chord was found fixed in the cadaveric position and normal in colour. When admitted the radial pulses and the pupils were equal, but in ten days' time the left radial pulse was found to be smaller than the right. On examining the precordium, the cardiac dulness was about normal, but the percussion note was impaired behind and to the right of the manubrium. The heart sounds were not materially altered, with the exception of a definite systolic bruit over the aortic area. No abnormal pulsation of any kind was noted, and tracheal tugging could not be elicited. He swallowed without difficulty or discomfort. His condition became steadily worse. The dyspnœa increased and occurred in paroxysms which were apparently relieved by amyl nitrite. The hæmoptysis persisted, the temperature remained normal, and the gnawing pain grew worse. It became increasingly difficult for him to lie down in bed. The dulness at the base of the left lung became more distinct, and I noticed that the skin over the site of the left lower lobe was slightly œdematous. He remained in this unhappy state for a few days, and was then suddenly attacked by extreme dyspnœa, increasing cyanosis, and great distress, which lasted about half an hour and terminated in death.

At the autopsy the pericardial sac was found distended with about a pint and a half of fluid arterial blood. There was a firm mass in the superior mediastinum in the region of the aorta. This extended into the posterior mediastinum, and completely surrounded the transverse portion of the aorta, growing up around its branches in the superior mediastinum. It completely encircled the innominate artery, the right subclavian and right carotid arteries, also the left carotid and subclavian arteries. The innominate veins and superior vena cava were lying on the anterior surface of the malignant mass, but not involved in the growth. The trachea was not infiltrated, and at its bifurcation the growth left the post-mediastinum and, encircling the left bronchus, narrowed its lumen and passed into the left lung. A most interesting condition existed in the pericardial sac. On its parietal layer a warty excrescence about the size of a shilling was found in the upper part of the posterior wall to the left, at which point the tumour was distinctly felt behind the pericardium, which had become infiltrated. The valves were not diseased. The wall of the left auricle was infiltrated by a spongy mass, spreading from the point of entrance of the left pulmonary veins, which in this case entered by a common orifice along the lateral wall to within half an inch of the auricular appendage, and for one inch along the posterior wall.

The auricular septum was not affected, nor had the growth passed the auriculo-ventricular groove. In the diseased area of the left auricle a perforation was found situated immediately posterior to the point of entrance of the left pulmonary vein. This perforation admitted the tip of the little finger. The first portion of the aorta was dilated and lengthened. The left lung showed thickening of the pleura and old adhesions everywhere, except at the base. It was dark red, collapsed, and deeply injected. The lower portion of the upper lobe was invaded by the tumour, which branched in all directions and was of a creamy colour. The centre of the mass had undergone fatty necrosis, and was semi-fluid. The root of the lung was composed mainly of tumour, which had infiltrated the lymphatic glands in this region. The œsophagus had escaped, though some of the lymph glands in its neighbourhood were involved.

Microscopic examination of the neoplasm proved it to be a small, round-celled sarcoma, which was actively invading the wall of the left auricle. For the careful description of the neoplasm, and the microscopical sections, I am much indebted to Dr. Halliday G. Sutherland, pathologist to the Hospital for Consumption and Diseases of the Chest.

In reviewing the facts of this case, it is of interest to note the points which might mislead in forming a diagnosis. The systolic bruit over the aortic area, the dulness behind the manubrium, the diminution in the volume of the left pulse, and the paralysis of the left vocal chord, constituted a "symptom complex" strongly in favour of aneurysm. On the other hand, the short history, the age of the patient, and the denial of syphilitic infection, the absence of pulsation and of diastolic shock, together with the presence of hæmoptysis, suggested mediastinal tumour. With mediastinal tumour, however, one would have expected involvement of the veins rather than interference with the arteries.

CASE III.—Small centrally placed empyema not discovered by frequent exploratory aspirations; diaphragm perforated by the pus which pointed below the costal margin; operation; death. Woman, æt. 35, admitted to the Stanley Hospital on May 11th, 1906, suffering from pain in the chest, pyrexia, and cough. She had been confined five or six weeks previously, and during the labour had lost a considerable quantity of blood. She recovered and was about again. Ten days before admission she fell ill with a shivering attack and a pain in her left side, but did not at once take to bed. When I saw her she was extremely pale. Six days before admission a herpetic eruption had appeared on her nose. Her temperature on admission was 102° F., pulse 108, respiration 40 per minute. She was hoarse, and complained of a stabbing pain in the left side of her chest on taking a deep breath. She stated that she was free from any cough. Her mouth was in a dirty state and her tongue pale and dry. The abdomen was not abnormally distended or tender; there was no unusual vaginal discharge.

Examination of the chest, made two days after admission, showed lessened movement on the left side and impairment of percussion note from the seventh rib down, the dulness being more marked at the extreme base and extending round to the left mammary line. Vocal fremitus and vocal resonance were both diminished. The breath sounds over this dull area were faint and bronchial in character. Anteriorly under the left breast a pleuritic rub could be heard. The apex beat of the heart was not displaced. As the outcome of this examination I diagnosed the presence of fluid, probably purulent in character. I inserted a large needle into the chest, first through the eighth and then through the ninth left spaces, about the level of the angle of the scapula, and was surprised and mortified with the result, which was negative, for I had just demonstrated the physical signs as those indicating the presence of fluid.

She had a rigor on May 12th, the day after admission, during which her temperature ran up to 104.4deg. F. There were two more rigors three days later. Although I was unable to locate the pus, I felt certain that the patient was suffering from septic absorption, and thought that she might receive benefit from the injection of anti-streptococcic serum. This was injected in doses of 10 c.c. daily, but without much, if any, benefit being observed.

On the 18th the spleen was found to be enlarged, and a rub could be heard over Traube's area. As the spleen was enlarged and the temperature persisted, and as the exploration of the thorax had proved negative, the possibility of typhoid fever presented itself; accordingly the blood was examined for the "Widal," with a negative result. A leucocyte count was made, which demonstrated a moderate leucocytosis. This, with the negative "Widal," made it very improbable that we were dealing with a case of typhoid fever. Her sputum at this time was frothy and viscid, and composed chiefly of mucus.

By the 21st the patient said she felt somewhat more comfortable, the tongue was cleaner, and her pain was less; the temperature, however, continued between 99 deg. and 102 deg. On the 22nd I again explored, and this time drew off 8 oz. of clear yellow fluid, slightly blood-stained towards the end of the aspiration. The fluid was alkaline, and loaded with albumen, and had a specific gravity of 1,020. On May 25th I again made an attempt to strike the pus, using a large needle and exploring three different portions of the left chest, and again the result was negative.

The temperature persisted, ranging from 99 deg. to 102 deg. F. There was a frequent pulse and rapid breathing. Her spleen was still easily felt projecting below the costal margin. By the end of May her condition was getting desperate, so I asked a surgeon to see her, and requested him to open the left chest and look for the pus. He declined, because its presence could not be demonstrated by an exploring needle. After this the condition of the woman became steadily worse.

On June 5th I detected some bulging under the left costal margin near the middle line, and this time on inserting a needle struck pus. An anæsthetic was at once administered, and about a pint of foul-smelling pus was drained from beneath the diaphragm. This, however, did not save her life, for she died the next day. At the autopsy we found that the primary condition had been a small empyema centrally placed, and at no point in contact with the chest wall (see fig. 1). It was situated in front of the root of the left lung, its internal boundary being the pericardial sac, its outer the visceral pleura and lung; below it was limited by the diaphragm, while above, the pericardial sac and lung met at an angle. The wall of the empyema was thick and tough. The pus had eroded the diaphragm, and formed a localised sub-diaphragmatic abscess which finally found its way to the surface below the left costal margin.

In this patient we have a good example of the great difficulties which sometimes offer themselves in diagnosing and locating small empyemata. Unfortunately the woman was debilitated as the result of a heavy and exhausting labour when she first took ill, and was in a poor condition to withstand any prolonged septic absorption. The duration of the illness was five weeks from the first shiver to the day of the woman's death. The recent delivery, the rigors, the continued temperature, the normal position of the apex beat, the enlarged spleen, the extreme anæmia, and the failure on three different occasions to strike pus, all added to the difficulties. It was a most distressing case to watch, and I publish it in the hope that its narration may be of help to others. Possibly a more favourable result might have ensued if we could have had the assistance of the Röntgen rays.

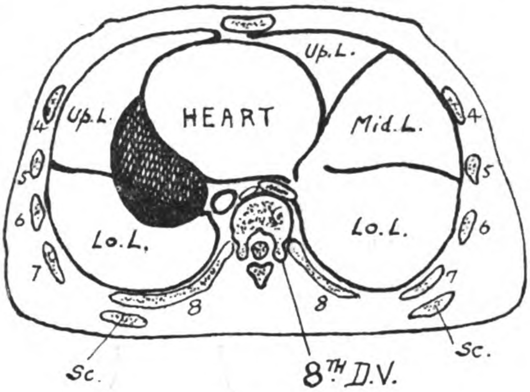

FIG. 1.

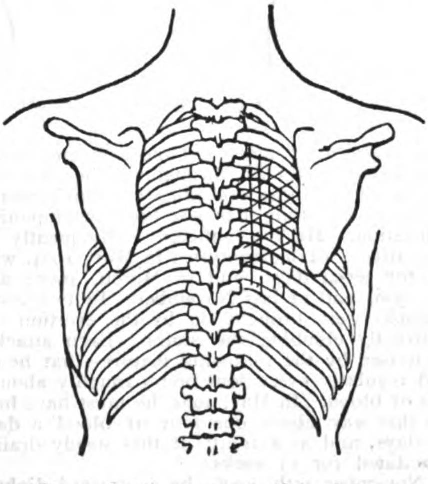

FIG. 2.—Chart showing area of slight dulness. Breath sounds diminished over same area. No adventitious sounds. Vocal resonance somewhat increased.

CASE IV.—Pulmonary syphilis. Fibrosis about the roots of the lungs; marked dyspnœa; cough; recurring hæmoptysis; few physical signs; cardio-pulmonary murmur audible at the open mouth. Man, æt. 36, complains of pain in the right side of the chest, great shortness of breath, and recurring attacks of blood-spitting. He worked as a monumental mason from the age of 14 to 23, with the exception of the two years when he was 18 and 19. When a mason his work consisted in dressing marble and limestone. Later he became a constable. When 27 he contracted syphilis. He consulted Dr. Logan five months after the primary sore, on account of a very bad throat, and was under continuous treatment for six months.

The history of the present illness dates back to five years ago; at that time he had been working very hard, and was feeling run down. His description of the onset of the attack is that, as he was cleaning some windows and reaching up, he felt a peculiar prickling sensation over the second intercostal space, just to the right of the sternum; this was at once followed by a rush of blood into his mouth.

The next morning he coughed up a clot which, on being floated out on water, was seen to be a "perfect cast" of a thick tube with two branches spreading from it; the thicker portion of it was of the calibre of a cedar wood pencil. Previous to this hæmoptysis he had not suffered from any cough or indication of chest disease—in fact, he tells me that he used to sing the bass solos in "the police minstrels." He recovered entirely from this attack, was free from cough or pain, and resumed his usual work. However, at the end of a year, he began to suffer from cough and dyspnœa on any exertion, and on this account had to give up singing. The cough and dyspnœa have persisted, becoming gradually more and more severe; and it is a remarkable fact that, throughout the illness, with the exception of those occasions on which there was hæmoptysis, coughing has not been accompanied by expectoration. He has suffered subsequently from several attacks of hæmoptysis: in May, 1904, when it lasted for seven days, and in March, 1905; also in April, 1906, and in last November. In two instances the attacks were brought on by the exertion caused by hurriedly climbing the stairs. Each attack was characterised by the following feature—that he expectorated regularly every four hours roughly about four ounces of blood. In May, 1904, he must have brought up in this way about one pint of blood a day for seven days, and as a result of this steady drain was incapacitated for 13 weeks.

On November 15th, 1906, he contracted diphtheria, and was in hospital for 23 days. In December he suffered from a peculiar pain about the region of the right nipple; the pain passed up into the neck and down into the right arm, lasting for days. He felt as though his "funny bone" had been struck. Since November 11th, 1906, he has been free from hæmoptysis. On February 5th, 1907, he again experienced severe pain in his chest, as described above; which extended into the armpit and down into the arm. Under treatment he is steadily gaining weight, and has put on five pounds in the last month. During the attacks of hæmoptysis the treatment has been opium and potassium iodide, and potassium iodide alone for the last few months between the attacks; under this treatment the dyspnœa has considerably diminished, and he feels much more comfortable. It is interesting to note that the potassium iodide was ordered before there was any suspicion that he was suffering from a syphilitic lesion of the lung. As he appeared to derive distinct benefit from its exhibition, it was continued.

The following is an account of his condition noted on March 5th, 1907:—Tall pale man, weight 11 st. 2½ lbs. Chest somewhat poorly developed, expansion equal; at the level of the fifth costal cartilage the chest measured 37 ins. at the end of inspiration, 33½ ins. at the end of expiration. On percussion I noticed that the right infraclavicular area was more resonant than the left, and that there was some impairment of note on the right side, posteriorly extending from about the third spinous process to the level of the ninth rib, being most marked in its upper portion. The breath sounds were fairly normal throughout the chest, but tended to be somewhat deficient and altered in quality over the dull area. The vocal resonance was slightly increased over the same area. There were no adventitious sounds of any kind. Dr. Hunt had some time previously examined the larynx, and declared it normal. While examining the patient, one most interesting physical sign was noticed—a definite systolic bruit could be heard on listening at the open mouth, and also on auscultating over the trachea. The area of distribution in the chest of this murmur is shown on the chart. It was loudest in the second and third right spaces, near the sternal margin, and was audible over most of the right chest in front. In the back it was just audible along the vertebral border of the left scapula. The deep cardiac dulness extended two inches to the right and four inches to the left of the mid-sternal line. There was some heaving of the lower end of the sternum and epigastrium.

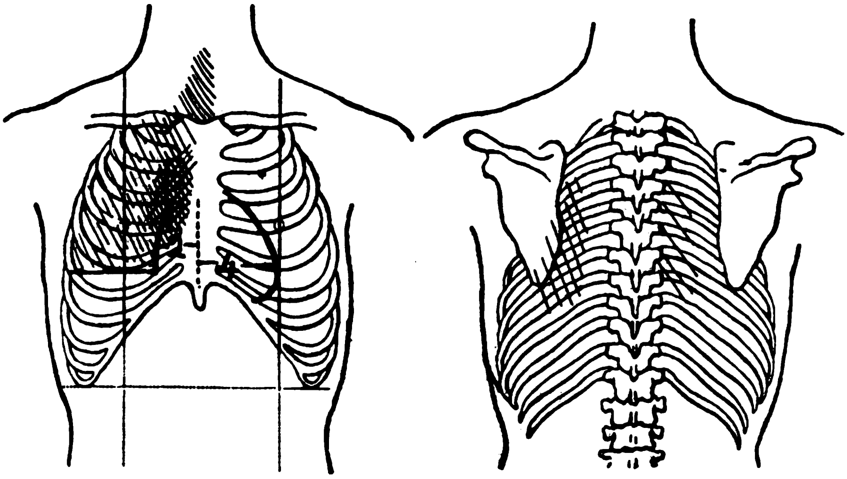

Fig. 3.—Chart showing the area over which the systolic murmur was audible.

The heart sounds were quite clear to the left, and over the aortic area the systolic bruit already mentioned did not seem to be associated with the first sound. This murmur persisted whether the patient stood up or lay down, and was more pronounced at the beginning of expiration. The pulse was frequent, over 100 per minute, soft and regular in time and force. The radial pulses were equal, and the pupils reacted normally and were of the same size.

Dr. Holland kindly examined the man's chest for me with the Röntgen rays. On the screen it was at once obvious that the excursion of the right side of the diaphragm was diminished, and that the right lower lobe did not appear to be so transparent as the left. The apices lit up fairly well. The heart and vessels were apparently normal. A photograph was taken, and the plate showed the presence of patches of thickening scattered through the central portions of the right lung, and also at the root of the left lung. There is nothing further to note except that there is no history available of night-sweats or of any abnormal temperature. The entire and continuous absence of expectoration has already been referred to.

On March 5th, the date of the examination of the patient, liquor hydrargyri perchloridi was ordered in combination with potassium iodide. Four weeks later I heard from the patient's medical attendant, Dr. Sykes, that the dyspnœa had become very much less distressing, and that the cough had almost disappeared. The cardio-pulmonary murmur remains unaltered. In this case the interest undoubtedly centres around the diagnosis, and the question arises—whether we are dealing with pulmonary tuberculosis which has undergone fibroid changes, or with a pneumonokoniosis, or, lastly, with pulmonary syphilis? I am inclined to look upon the case as belonging to the latter class. There can be no doubt that in this patient there is a scattered fibrosis at the roots of the lungs, extending chiefly into the right lower and middle lobes; the question is simply as to the nature and cause of the lesion.

It is very generally accepted by authorities on pulmonary syphilis that syphilis is much more prone to attack the root of the lung, the middle lobe, and the central portion of the lower lobe than the apices; in fact, Grandidier states that a dulness in the interscapular region, extending as far as the middle of the base of the right scapula, is almost pathognomonic of pulmonary syphilis. Fournier describes three degrees of pulmonary syphilis: the first, in which the disease is latent and unexpected; the second, in which there is dyspnœa but no constitutional disturbance, with the physical signs of induration or cavitation; and the third, which is severe in type and presents all the features of well-marked consumption. The marked and persistent dyspnœa, out of all proportion to the objective signs in the chest, is frequently referred to as very characteristic of syphilitic disease of the lung, and is certainly a prominent feature in this case. It is probably the result of sclero-gummatous changes in and around the bronchi at the root of the lung. Again, in favour of syphilis are the persistent absence of fever and the freedom of the apices from disease. If the lesion were tubercular, it is hardly likely that the apices would have escaped, and also that there should have been such a complete absence of cough during the year following the first hæmoptysis.

Again, if it were tubercular, one would have expected that at some period of the disease signs of constitutional disturbance, such as fever or night-sweats, would have shown themselves; these were, however, absent. The fact that the dyspnœa diminished, and that the patient gained weight under anti-syphilitic treatment, is strong presumptive evidence in favour of the syphilitic theory. Potassium iodide, as we know, when given to tubercular patients, tends to increase the number of the adventitious sounds, so much so that Turban advises its administration to patients for diagnostic purposes. In this man the exhibition of potassium iodide left the lungs persistently dry. Again, four years before any sign of chest trouble, the man without doubt suffered from syphilis, which appears to have been his only dissipation. There is another possibility—that he may have contracted pulmonary trouble when working among the marble and limestone. The short period of duration of this work (five years only), and the long period of complete immunity from any symptom of chest disease after ceasing to follow this occupation, render this assumption improbable.

We are therefore constrained—largely, I think, by a process of exclusion, to adhere to the diagnosis of pulmonary syphilis. The explanation of the peculiar murmur is not easy. I look upon it as cardio-pulmonary, but I must confess that when I first heard it, it suggested to me the possibility of a deep-seated aneurysm. But this view received no corroboration from the examination with the Röntgen rays, and it is not usual to find an aneurysm leaking into a bronchus over such a long period as five years. Long before that time had elapsed it would either have burst, or the diagnosis would have ceased to be a matter of doubt.

ACUTE PANCREATITIS AND MULTIPLE FAT NECROSIS.

By F. G. BUSHNELL, M.D.,

Pathologist to the Sussex County Hospital (Stephen Ralli Memorial) Brighton.

A. T. 3.—Æt. 40. The patient was admitted on January 14th, 1906, under the care of Mr. Ionides, F.R.C.S., Surgeon to the Sussex County Hospital. Twenty-four hours previously she was taken with sudden epigastric pain. There was no sickness. The abdomen moved well. The pulse-rate was 80, and the temperature was normal. The bowels were open 24 hours before onset of pain.

On January 15th pulse-rate was 120. There was tenderness in epigastrium and right iliac fossa. The abdomen worked well in upper part. Operation by Mr. Ionides.

Some smoky fluid was found on opening the abdomen. Numerous omental and subperitoneal fat necroses were seen, but the pancreas was not swollen. The appendix, tubes, and ovaries were natural. There was a small fibroid in posterior wall of uterus. The cavity was washed out and sewed up.

She sank gradually, and died on January 16th, 1906, at 12.30 p.m. The post-mortem was made on January 17th, by Dr. Reynolds, M.B. The abdominal walls were 8 ins. thick; fat was increased in omenta; there was turbid, sanious fluid in abdomen. The foramen of Winslow was patent. The parietal and visceral peritoneum were covered with areas of fat-necroses, from a pin's head to a pea in size, especially around the pancreas and in small sac. The stomach, duodenum, and intestines showed no signs of catarrh to the unaided eye. They were not thickened or thinned. About 3 centimetres from the entrance of common duct was a swelling, about 1.5 centimetres in size, oval, firm, and movable below mucosa. Cæcum and colon walls were thick, hyperæmic; liver enlarged and red, but ducts not dilated. The gall-bladder contained chocolate-coloured bile, but no calculi and no signs of catarrh. The pancreatic duct joined the common bile-duct about 3 centimetres from end, and was patent, narrow, and its walls thin, but contained no calculi. Pancreas measured 16 centimetres in length; its tissues were firm and doughy; section showed areas of hæmorrhage, recent and of longer duration. Its colour was pale yellow, beefy and dark red. It was œdematous. The radicles of splenic veins thrombosed, as also was the vein itself. The splenic, hepatic, coronary and superior mesenteric arteries contained a little fluid blood. The aorta showed atheroma about the entrance of the cœliac axis and superior mesenteric artery. The mesenteric and lumbar glands were somewhat enlarged and yellowish, soft; some showed blood extravasations. Spleen was slightly enlarged, its pulp soft and diffluent. Peripancreatic tissues were œdematous; fat-necroses were numerous. There were soft, semi-fluid areas of light chocolate colour, especially seen over right kidney. The kidneys were enlarged, of a dark red colour, firm, and the capsule stripped easily. The surface was mottled; cortex and medulla of about normal ratio. The pelvic fat was increased.

Microscopic Changes.—The pancreas showed hæmorrhages and areas of necrosis, with leucocytic zone at borders, evidently of ante-mortem origin. The nuclei showed karyolysis, karyorrhexis, and pyknosis in necrotic areas. The interlobular vessels were engorged. Areas of tissue resembling latticework were seen. Islands of Langerhans unaffected. No bacilli were seen. Epithelium of ducts was, in places, desquamated. Vessels contained leucocytes and shed endothelium; others were thrombosed; some were necrotic. There was no clear evidence in sections examined of arteriosclerosis. There were bundles of radiating crystals as of fatty areas and calcium.

Liver.—The periphery of lobules showed fatty degeneration, and the parenchyma cloudy swelling and congestion. No amyloid change.

Kidney.—Showed cloudy swelling of the tubules; the convoluted tubules, or intermediary part, escaping. Malpighian bodies showed slight increase of nuclei. No hæmorrhage present. No amyloid changes. There was decided congestion. Interstitial changes were not present.

Duodenum.—The duodenum showed necrotic condition of mucosa and a polyadenoma of Brünner's gland.

Spleen.—The spleen showed congestion.

A smear from pancreatic juice showed cocci (in pairs and threes), Gram + and — diplococci, bacilli capsulated, and short streptococcal chains.

The culture from gall-bladder showed colon-like bacilli and cocci in pairs and short chains, Gram +.

The bacillus isolated gives characteristics of the bacillus coli communis.

Gelatine.—Streak, moderate white growth. Stab, moderate white growth, no liquid.

Shake bubbles on third day.

Agar.—Luxuriant, moist, whitish growth, iridescent. Microscopic appearance: bacilli, straight, round or pointed ends, in pairs or singly, Gram —. From gall-bladder, also diplococci and short chains of cocci were obtained. From pancreas, a coli-like organism and some large bacilli with square ends, Gram +, grew in broth.

Several cases of this fatal and interesting affection have been recorded in the *Lancet* and in the *British Medical Journal.* It may be compared to a gastric erosion in respect of the ease and extent to which grave hæmorrhage follows on small local damages to tissues which have a powerful (digestive) secretory function. The origin of the local damage may vary, being circulatory, septic, or due to changes in the vessel wall in different cases.

The fat necroses are certainly secondary to the abnormal diffusion of the steapsin of the pancreatic juice and its subsequent action in the fat. A summary of the chief experimental work bearing on the subject is as follows:—

(1) Flexner produced acute hæmorrhagic pancreatitis by injecting gastric juice into the duct of Wirsung, and Opie by injecting bile in dogs.

(2) Opie, by ligating the pancreatic ducts of cats, produced necrosis of the abdominal wall fat, and of fat elsewhere.

(3) Endarteritis is described by Dürck in the pancreatic vessels, also embolism or thrombosis.

(4) The presence of bacteria in the pancreatic juice and duct is stated by Metchnikoff to be usual in the vertebrata.

(5) The fluid from these pancreatic cystic swellings may be sterile (*British Medical Journal*, February 27th).

(6) Flexner has demonstrated steapsin in fat necroses which are frequently sterile.

(7) Fat necrosis may be caused by the action of the pancreatic juice, but not by trypsin (Hildebrand and Dettner).

(8) H. A. Williams produced fat necroses by placing pieces of pancreas under the skin and into perirenal fat of dogs.

(9) Duodenal catarrh, biliary calculi, bacterial injection of pancreas, renal cirrhosis, and alcoholism are frequently associated with the disease (Mayo Robson).

P.S.—The specimens and microscopic preparations were exhibited at the Brighton and Sussex Medico-Chirurgical Society. The lantern-slides were by Dr. Spitta and Mr. Caush, L.D.S.

CLINICAL RECORDS

ROYAL INFIRMARY, GLASGOW.

OUT-PATIENT DEPARTMENT.

Emphysema,

By JOHN T. MACLACHLAN, M.D.

IT is astonishing to find how many patients suffer from emphysema of the lungs. Patients frequently come to the dispensary complaining of an annoying cough—it may be only of a few weeks' duration. When the chest is examined, the semi-tympanitic percussion note at once raises the suspicion that emphysema is present. Then we find the normal cardiac and liver dulness reduced by the overlying emphysematous lungs. The respiratory murmur is found to be unduly slow and protracted. Not infrequently the breast-bone projects, and the spine is unduly curved, giving a rounded appearance to the shoulders. The chest in typical cases is barrel-shaped. When we inquire into the past history of such cases, we find there has been a winter cough, subsiding or disappearing during the summer months of the year, but after a few years there is a morning cough all the year round. This morning cough is very harassing, as there is very little expectoration, and what there is is often described as "a small pea," which seems to tickle the throat, and the patient is not right until he gets it up. Going upstairs, or hard exertion, brings out the disabled condition of the lungs, as the patient becomes breathless. At times a certain amount of asthma is present, and their bed-fellows hear the cooing, wheezing, and whistling sounds produced during respiration from the spasm of the bronchial tubes. When the patient gets a fresh dose of cold, he seeks advice, but it is impossible to cure the organic changes present. We may get rid of any recent catarrh by expectorants and small, guarded doses of opium. Afterwards we may endeavour to arrest, if possible, the progressive emphysematous state.

We must find out what is keeping up the irritation. Certain trades, such as that of a potter, or that of a hewer of stones, are responsible for certain cases. Chronic whisky drinking is perhaps the most common cause in this country. The rheumatic and gouty states contribute their quota. Syphilis is likely to be a fertile source, although not easily demonstrated. Cardiac disease may be a predisposing cause, and will certainly aggravate the condition. Sometimes a persistent cough may be the chief sign of cardiac disease, and digitalis will then act like a charm. Change of temperature affects emphysematous patients greatly. Thus going to bed usually starts the cough, or rising from the warm bed in the morning. Then strong tobacco smoke and dust may excite much coughing. The following scheme of treatment may be found useful:—

(1) Remove vascular congestion by keeping patient in an even temperature; a milk diet, medicines such as antimony, ipecacuanha, sweet nitre, and diuretics, with occasional purgatives.

(2) Remove cause, if possible.

(3) Treat diathetic conditions, such as rheumatism, gout, etc., with alkalies, iodide, etc.

(4) Astringent sprays to harden mucous membrane.

(5) Harden the skin by brine baths, tepid or cold sponging.

(6) Finally, tonics, especially the compound syrup of the hypophosphites.

OPERATING THEATRES.

KING'S COLLEGE HOSPITAL.

OPERATION FOR COMPLICATIONS OF MASTOID DISEASE.—MR. PEYTON BEALE operated on a boy, æt. 14, who had been admitted in the summer with the following history:—Three weeks previously he had had suppurating otitis media; an abscess had pointed behind the ear, and had been opened and drained by a doctor in the country; a discharging sinus remained, and bare bone was felt at the bottom of it. Soon after admission a vertical incision was made through the sinus and a large portion of the temporal bone, including part of the petrous and mastoid portions was found quite loose and was removed. All discharge ceased in a few days; the wound was healed in a fortnight, and the boy was sent to a convalescent home with instructions that he should be watched very carefully for the onset of any cerebral symptoms. The boy was certainly wanting in intelligence, and was slow in speech and in movement, but how much of this was natural it was impossible to say. When he had been at the home about fourteen days he was suddenly seized with violent frontal headache and vomiting, obviously cerebral in origin;

he was drowsy, the temperature was subnormal, and the pulse slow. He was promptly sent back to the hospital, and on being watched for a few days it was quite obvious that he was suffering from cerebral compression; he was therefore trephined over the temporo-sphenoidal lobe of the same side as the ear disease. The brain was found to bulge considerably, and was explored in all directions through the trephine opening, first with a probe and then with the little finger. The white substance was unusually soft, and a good deal escaped in the process; the lateral ventricle was then tapped, and about four ounces of perfectly normal cerebro-spinal fluid, under considerable pressure, withdrawn. The symptoms of compression were at once relieved, and for three or four days the boy appeared to be going on well; then all the symptoms returned, and the lateral ventricle was again tapped with the same result. The boy again became worse in a few days, so it was decided to trephine over the opposite temporo-sphenoidal lobe with a view of tapping the other lateral ventricle. This was done with the same result, the boy again becoming better, and again relapsing in a few days. At this stage both discs were normal, the pupils were equal, there was no general paresis or sensary disturbance, but there was slight one-sided facial paralysis and slight aphasia. The boy was then thoroughly overhauled, and it was found that there was slight optic neuritis on the left side, some nystagmus, vertigo, and inco-ordination; an opinion was given that there was in all probability a right cerebellar abscess. The right cerebellum was therefore trephined, and explored in all directions; it bulged considerably into the wound and a good deal of the cerebellar substance escaped. The opposite cerebellar lobe was also explored, but nothing was found. A long tracar and cannula was then inserted, so as to again tap the posterior part of the right lateral ventricle, and three or four ounces of fluid, again perfectly normal, were thus removed. The symptoms were again relieved, but in about a week's time they recurred. Lumbar puncture was then performed, cerebro-spinal fluid thus removed was found to be normal. After this the boy appeared to be doing well, the pulse rate quickened, the temperature rose to normal, and then to about 100. The cerebellar wound at this time was quite normal, and had healed with the exception of one place, where a gauze drain was kept. The wounds made for the cerebral trephining were both soundly healed, but the original wound at the back of the ear was still discharging. It was now found that the patient had some foul discharge from the meatus on the opposite side; a mastoid operation was therefore done here, and the wound in due course healed. After this his temperature remained above normal, and in a few days some foul smelling pus was found coming from the cerebellar trephine wound, from which it was assumed that there had been an intra-cranial abscess deep in the cerebral or cerebellar tissue, probably the former, which had not been found at any of the previous operations, but which had lately increased in size and burst through the cerebellum.

Mr. Beale said that after all these complications extending for a period of over three months the boy was still in the hospital, and that his general condition was in no way worse than when he left the convalescent home, except that he was somewhat weaker, but that at the present time there were no marked cerebral symptoms.

We hope to report further upon this case in Operating Theatres.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, DECEMBER 13TH, 1907.

The President, E. H. TWEEDY, M.D., in the Chair.

The PRESIDENT showed, for Dr. DUKE, a self-retaining tenaculum for cervix, and an apparatus for the rapid removal of swabs from a Playfair's probe.

Dr. HENRY JELLETT exhibited (*a*) Uterus showing unusual thinning of the muscle of the fundus after pregnancy; (*b*) double carcinoma of the ovaries secondary to double mammary cancer. The first specimen, he said, was of interest, not on account of the condition for which it was removed, but for the condition found present after removal. The patient, who was thirty years old, was sent to him suffering from carcinoma of the vagina. There was a large patch on the posterior vaginal wall involving about the upper third of the vagina, and though it was separate from the cervix, it had a tendency to extend into the right fornix. The rectum was free. He considered the case was operable, provided he could operate by the abdominal route, and he decided to do so. The patient had had a baby four weeks before going into hospital. On the night before the operation her temperature rose to 104° F., and she got severe rigors. On the morning of the day of the operation her temperature was still 104°, and her pulse anything up to 140. Having to leave town, he was in a difficulty as to how to deal with the case; operation was contra-indicated, and so he thought it best to wash out the uterus and see if he could find the cause of the rise in temperature. Before doing so he passed a sound, and this passed into the abdominal cavity straight through the fundus, whose resistance was quite inappreciable. He did not like to leave a probably septic uterus with an opening into the peritoneum, and so he removed the uterus by the vagina and as much of the cancerous vaginal wall as he could. After the operation, he split the uterus to see why the sound had gone through it, and he found that there was a cone-shaped excavation extending through the fundus almost up to the peritoneum. The rest of the wall preserved its normal thickness. Microscopical examination of the fundus showed no evidence of malignant growth. The only explanation he could offer as to the cause of the perforation was that the placenta had exercised an eroding influence on the uterus at one spot. The patient got better for a time, but died about two months afterwards of general metastases, *plus* weakness. The second specimen was two carcinomatous ovaries removed from a patient on whom Dr. Haughton had performed a double-breast operation about six months before. There could be no doubt that the ovarian tumours were secondary to the breast tumours.

Dr. HORNE expressed great interest in the case, as he had had to perform a similar operation recently on two patients, both comparatively young, thirty-two and thirty-four. In one case, when he traced the broad ligament into the left ovary, he found a mass of cancer, of which he would have known nothing if he had attacked the case by the vaginal method. Three months later she had symptoms of return, and he found another mass of cancer high up in the abdomen.

The PRESIDENT exhibited a double pyosalpinx removed intact. He said the patient complained only of sterility. She had no pain, and she did not look ill. She was young, two or three years married, and had been sent to him to be curetted. He palpated the tumours, and diagnosed double ovarian cyst; the uterus was felt lying between them. He was very much surprised to find that they were really very large tubes. They were taken out, joined together, and without difficulty. The point of interest was that he hoped he had thus cured the patient's sterility. There was one ovarian cyst, which was removed. The other ovary was resected, and a good sound piece left behind together with healthy tube stumps.

DISCUSSION ON THE CHANGES WHICH HAVE BEEN SUGGESTED BY THE GENERAL MEDICAL COUNCIL IN THE METHOD OF TEACHING PRACTICAL OBSTETRICS.

Sir **William Smyly** opened the discussion with an address, which will be found in another column under the heading of "Original Papers." In the discussion that followed—

Dr. **Horne** said the subject was of particular interest to Dublin, which was practically the home of obstetrics. The Dublin School for a great number of years had rightly insisted that the course of study should be a comparatively long one, and the General Medical Council, in order to raise the standard of both England and Scotland, had offered to compromise with Dublin by suggesting that the period of study should be three months. The question of examinations was of great importance. There were great difficulties in the way of taking a number of students to a lying-in hospital to have them examined, but he believed with Sir William Smyly that the difficulty could be overcome. He did not see why men could not be brought for examination to a lying-in hospital just as they were brought to a clinical hospital for examination of the chest. A grave defect in the teaching at present was that the students had only to satisfy the registrars of the various licensing bodies that they had taken out their midwifery attendances. He would like to see men compelled to take out from forty to sixty clinical attendances during the three months. Midwives in Dublin were in a far better condition than students, as they were under the full control of the hospital; they were obliged to attend regularly day after day; they attended to the lectures, to the cliniques, and they saw cases from day to day. The students did not do so. He thought they were all agreed as to the first recommendation of the General Medical Council. As to the second, a great difficulty confronted them. Annually in Dublin something like two hundred students had to take out their course of midwifery. If they simply attended for three months, it would be utterly impossible to supply them with material for each man to take out his twenty conductions. The period was too short. How it would be accomplished in England he did not know, but he felt that if they in Ireland were unanimous and kept to their rules, they would be still far in advance of the recommendations of the General Medical Council, and would have nothing to fear from them. The Dublin school had up to the present been recognised as the principal obstetrical school in the United Kingdom, and he did not believe that the keeping up of their standard would cause a single pupil to leave the country.

Dr. **Kidd** said he had always impressed on students the fact that when they were taking out their practical midwifery they were for the first time face to face with a practical side of their profession, which involved the safety of two lives. He therefore agreed that every student should have the experience recommended by the General Medical Council. He deprecated the desire to attend practical work before theoretical lectures. There was no subject in which it was more necessary to have a thorough knowledge of the theory before the practical was attempted. He thought the higher mortality in Ireland in obstetrics was due to the fact that while they could—to use Sir William Smyly's figure—bring the horse to the water and make him drink, they could not make him keep on drinking. It was an established fact that the mortality in lying-in hospitals was lower than that of general practice in the country, notwithstanding that the dangers to a woman in a hospital were greater than those in private practice, and the cases were more morbid and serious. It was, therefore, forced upon them that the doctors and nurses did not carry out in general practice the same strict rules of asepsis as in the institutions where they were taught to do so. He thought that the practical aspect of examinations might be improved if it were made compulsory on students to have attended not only a number of cases in the house under the supervision of the medical officer, but also at the end of their period to give clinical notes of the whole course of the puerperium, for at least five cases. He thought that the education of the student should be such as to enable him to detect when any case was abnormal, or becoming abnormal, so that he might then know that he should seek the assistance of those placed in supervision over him. As regards the period of six months, he felt that a man who lived in the precincts of a hospital for one month would, in all probability, lay up a greater store of knowledge than one who attended a lying-in hospital two days in the week for three months. The midwives, under the present rules, had an opportunity of being trained in even a more practical way than the students.

Dr. **Purefoy** said they agreed that the clinical character in the examinations should be present in a greater degree than it had been, and an endeavour should be made now to bring it about. He suggested that some arrangement might be made with the masters of the hospitals, by which the obstetrical examiners of the colleges might make a monthly visit and have opportunity given to examine certain students. This would obviate the difficulty of carrying out the practical examination for a large number of students at one time. The additional advantages thus secured by the students was an important consideration. He thought an effort should be made to develop the plan of encouraging students to reside, even for one month, in some of the maternity hospitals. He did not think they should be in a hurry to adopt the General Medical Council's recommendation as to three months' attendance, except, perhaps, to the extent of allowing a certain number of students, who might particularly desire to do so, to take out their number of cases in that period. He also thought that some practical advance might be made if a committee of the masters and assistant masters were formed to carry out some of the suggestions which had been made.

Dr. **Henry Jellett** said the two points that appeared to him to stand out with special importance were the institution of practical examinations, and the regulations governing students' practical instruction in maternity hospitals. With regard to the first, he would only say that while he had no doubt as to its extreme advisability, he had doubt as to its practicability at present. They were all probably agreed that the recommendations of the General Medical Council were extremely good, with the exception of the alteration in the course of attendance at maternity hospitals from six to three months. In Ireland such an alteration would shorten the present course, whereas in England and Scotland it would raise it to a much higher standard than before. He was quite aware that the present state of affairs was open to the objection that all students did not attend the full course. This fact was due to the regulations of the licensing bodies, which regulations were capable of improvement, though they were very many degrees ahead of the regulations on the other side of the water and considerably ahead in their potential capacities of the recommendations of the Council. They all wanted to teach students properly, both to maintain the reputation of the school, and, still more, that students might be sent out with a proper training. Why, then, should they limit themselves to what was practicable on the other side of the water? A three months' course presented the great practical difficulty that students could not be given their twenty cases in so short a time. Students had a habit of going to maternity hospitals at certain months, which were free from examinations and lectures, and if limited to a three months' course, a student would frequently be unable to complete his necessary number of attendances or conductions, and the onus would then be thrown on the hospitals to provide cases and to provide extra time. He thought that an intimation from the hospitals to colleges as to the impracticability of providing twenty cases for every student in three months would show the difficulty of the matter to those who did not understand it. It was absurd to think that students would be driven out of the country by the present system, since the difference between the courses in Ireland and in Great Britain will be lessened instead of being increased. He thought the Section might suggest to the colleges, in a resolution, that some more definite regulations should be laid down to govern the attendance of students at maternity hospitals. In the recommendations of the General Medical Council, the student is required to attend regularly for three months, but there is no definition as to the meaning of the word "regularly." He thought that if the colleges adhered to their six months' course, and made some attempt to define regular attendance, they would not only maintain, but enhance the reputation of the Dublin School, and would make the obstetrical training of the greatest value to the student.

Dr. **ROWLETTE** said that the medical curriculum seemed at present to be over-weighted, and if any part of it was to be increased, other parts would have to be diminished, and the clinical teachers must impress on their brethren who taught the more purely scientific branches at the beginning of the course that that part must be cut somewhat short. The reason why the student took the minimum quantity of instruction in midwifery and gynæcology was that he was worn down by the earlier studies, which were made so great and difficult that his clinical work was often crowded into the last eighteen months. If teachers of anatomy and physiology were capable of doing their duty, botany and zoology were unnecessary. There were certain faults in the final examinations in midwifery and gynæcology, which, being taken away, the subjects would be more attractive to students: one was the excessive amount of surgery required by the gynæcological examiner; it was no part of the duty of an ordinary medical practitioner to be able to perform highly technical operations. If the student was going to be a specialist, he must make up his work after his qualifying examination, not before it. He was only referring to highly technical operations; operations of emergency must, of course, be within the knowledge of every medical man. As to the high mortality in private practice, he thought it might be explained by the fact that more cases of childbirth were left unattended by medical men in Ireland than in England. It was also quite impossible for a medical man to practise the same aseptic precautions in a country cottage as in a hospital.

Dr. **TREVOR SMITH** said that much of the fault for the existing state of things lay in the fact that many of the nurses turned out were of a very inferior class. Illiterate nurses who did not know the use of the thermometer were often left in charge of women without the assistance of a medical man. He was not referring to the handy woman, but to so-called nurses who held diplomas.

The **PRESIDENT** said it was pleasant to see with what unanimity the members of the Obstetrical Section opposed the suggested curtailment of the period at present deemed necessary for attendance at maternity hospitals. Outside this section he regretted to say that many teachers were of opinion that a six months' course of study of midwifery and gynæcology was quite unnecessary, and unless energetic action was taken he much feared that the Royal Colleges would cut down the course to three months. He was certain this step, were it adopted, would make it very difficult for the maternity hospitals to deal with the number of patients they at present attend. He agreed that the present regulations of the licensing bodies in respect to midwifery required alterations, but the change should not be a retrograde one. These bodies should determine in the first instance precisely what they mean by an attendance for six months. If they do this they may rely upon the hospitals to enforce their regulations. At present the six months' attendance was interpreted in a very loose manner by some students, and those who desire to evade the course could, to a large extent, do so. On the other hand, many men considered it a great privilege to be permitted so long a course, and it was to these men we look to sustain the future reputation of the Dublin School of Obstetrics.

It was then proposed by Sir **WILLIAM SMYLY**, seconded by Dr. **JELLETT**, and passed unanimously:—"That the Obstetrical Section of the Academy of Medicine regards the recommendations of the General Medical Council regarding Obstetrical teaching as, in many cases, a very great advance on the present conditions. The Section, however, considers that the suggested alteration of the period of attendance on a maternity hospital from six months would not be advisable or practicable. The Section considers that, instead of reducing the attendance, the licensing bodies should adopt such regulations as will ensure regular attendance of students at the clinical teaching of the hospitals. With regard to the adoption of a practical examination in midwifery and gynæcology, the Section considers that such a step is most desirable, and urges its members to aid it by all means in their power."

Dr. **PUREFOY** then proposed, Dr. **KIDD** seconded, and it was passed unanimously:—"That a committee consisting of the masters, assistants (past and present) of the Dublin Maternity Hospitals be appointed for the purpose of urging upon the licensing bodies the inadvisability of changing the course of practical obstetrics from six months to three months."

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, DECEMBER 19TH, 1907.

The President, Mr. **FRANK T. PAUL**, F.R.C.S., in the Chair.

PLASTIC OPERATION BY THE TAGLIACOTIAN METHOD.

MR. **G. P. NEWBOLT** showed lantern slides of a case operated upon by the above method. The patient's forearm had been severely injured in a railway accident, both bones being broken, the skin much lacerated, and the muscles and tendons partially torn away. A long flap of skin was raised from the abdomen below the left breast, and the arm passed under it, so that it lay as if in a sling. As a result of this operation, which was completed in two further stages, the arm had been saved, sensation was good, and there was some movement in the fingers. The patient was still under treatment.

TREATMENT OF UN-UNITED FRACTURE BY BONE GRAFTS.

Mr. **RUSHTON PARKER** related two cases of un-united fracture treated by cleaning out unossified tissue from between the fragments, and planting in the interval small pieces of bone clipped from the seat of fracture. One case was that of a carter, æt. 35, whose left humerus had been broken six months previously, and imperfectly united by incomplete callus, permitting movement and unfitting the limb for use. Union resulted in six weeks. The other case was that of a lady, æt. 48, with total non-union of the left ulna of eight months' standing. There was pain as well as weakness and flexibility at the seat of fracture. Union was still absent in six weeks, but after hammering the seat of fracture, resulted firmly a week later. The practice was based upon the principle laid down by Sir William Macewen in his celebrated case reported to the Royal Society in 1881, repeated and amplified in his lecture at the University of Liverpool in December, 1906, again related to the Royal Society in January, 1907, and published in the *Proceedings* of June, and in the *British Medical Journal* of June 22nd, 1907.

The **PRESIDENT** said he quite accepted the truth of Sir William Macewen's observations, on which Mr. Parker had based his treatment of these interesting cases; but he did not consider that these observations contained the whole truth in reference to the development of bone. If so, how were they to explain the formation of bone in various tissues such as arteries, where no bone cells had ever existed. The constant precursor in such cases was a calcareous degeneration. If this excited any inflammatory change, the young connective tissue formed bone. Calcified arteries, cysts, tumours, etc., in this way frequently originated bone in the neighbourhood of the calcareous deposit, and he would suggest that Mr. Parker tried the effect of the presence of phosphate of lime alone, as this could be introduced without a regular operation.

Mr. **T. C. LITTLER JONES** showed a patient, both of whose feet he had amputated on account of the condition known as tabetic or trophic foot. Lantern slides were shown of X-ray photographs of the feet at various stages of the disease, exhibiting very clearly the progressive melting away of the phalanges without primary inflammatory changes. The patient had none of the ordinary symptoms of tabes dorsalis, appeared to be in excellent health, and could walk remarkably well on his artificial feet.

PHYSIQUE AND HEALTH IN THE LIVERPOOL SCHOOLS.

Dr. A. S. **Arkle** read a paper on the above subject, based on his examination of children from schools of three classes under the control of the County Borough Education Committee and the boys of a public school. The statistics showed clearly that there was a close relation between status in life and feeding and the growth and development of the children. The influence of feeding was shown by comparing the children of industrial schools and those of the lower class of Council schools. In regard to health, attention was drawn particularly to heart lesions, abnormality of the eyes, ears, nose, throat and teeth.

Dr. T. R. **Glynn** said that some of the facts demonstrated by Dr. Arkle's figures might have been anticipated, but others—as the smaller number of congenitally syphilitic children—was contrary to what might have been looked for. The explanation was in some degree the early death of the infected children. He hoped Dr. Arkle would have an opportunity of extending his observations in other directions, such as the relative prevalence of hereditary degeneration.

Dr. E. V. **Hope** mentioned that the excellent work which had been done by Dr. Arkle during the last few years gave some indication of the magnitude of the task of the medical inspection of school children. It was absolutely necessary, as the excellent Memorandum of the Board of Education pointed out, to follow up the examination by an extension of the amelioration of the sanitary condition, which had already proved so powerful a factor in improving the health of children. The methods of carrying out the Act had not been decided upon, and Dr. Hope expressed the belief that the views of the medical profession, if focussed and brought to the notice of the Education Authority, would receive every consideration at the hands of that body. He regarded the medical inspection of school children as an extremely important accessory in public health administration.

Mr. J. **Bark** agreed with Dr. Hope that the Education Department's object was to prevent the occurrence in children of certain diseases, which were detrimental to their physical and intellectual future. In the case of adenoids, the earlier the removal was undertaken the better. The best results were obtained in children operated on between the ages of two and seven years. Ninety per cent. of young children with enlarged faucial tonsils had adenoids. If the new Act was carried out efficiently, the future generations would be freer from deafness and chest troubles than the present. Dental examination and treatment were most important. Oral sepsis was responsible for much of the physical deterioration of our race.

Dr. A. C. **Wilson**, Medical Officer to the Truant Schools at Hightown, said he agreed with Dr. Arkle that under-feeding was the great cause of bad physique in the poorer classes of children. He rarely met with congenital syphilis, and this he attributed to the infected children dying out or getting into special Institutions for the deaf and dumb, blind or imbecile, etc. The most pressing reform needed was the better care of the teeth. He was glad to say that the Liverpool Education Committee had recently appointed a dentist for all Liverpool schools. He believed that defective vision in children was to some extent due to the eye not being trained to distances.

Several other members having spoken, Dr. T. R. Glynn proposed, and Dr. G. Stopford Taylor seconded, the appointment of a sub-committee of the Institution to consider and report on the Memorandum of the Board of Education. This proposal was adopted, and a sub-committee elected.

Somerset County Council and Medical Officer of Schools.

A long discussion took place at a meeting of the Somerset County Council, held at Taunton, regarding the medical inspection of children attending elementary schools. The County Education Committee announced their intention of appointing a chief medical inspector, who should give his whole time to the duties, and receive a salary of £500 per annum.

CORRESPONDENCE

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Jan. 5th, 1905.

Pulmonary Consumption

Prof. Renon gave recently some very interesting clinical lectures on the modern practical methods of treating phthisis. These lectures were published in the *Journal des Praticiens*, and merit reproduction :—

I hesitated for a long time (says Prof. Rénon) to treat this subject, as I had no sensational discovery to announce, nor had I found a specific remedy for tuberculosis. But at the recent Medical Congress the papers read on the treatment of consumption were so contradictory in their conclusions that I was convinced of the necessity of taking up the study of this treatment, which presents so much difficulty to the general practitioner. Some advise purely hygienic treatment, air cure, and supplementary feeding. Above all, no drugs, which simply poison the patients. Others recommend just as strongly the treatment by serums and tuberculins—serums of Maragliano, Marmoreck, tuberculin of Koch, Denys, or of Beraneck. Still others proclaim the advantages of sea water serum in large doses.

In face of propositions so radically different, it is difficult for the practitioner, if he has not acquired sufficient personal experience, to know exactly what to do.

From time immemorial new treatments for consumption have been tried, and recourse has been had to most curious methods, according to the medical doctrines of the period, and frequently with some success.

For a long time, for instance, tuberculous patients were treated with red cabbage; they were given it to eat in various make-ups and also as syrup. This treatment gave certain results from the fact that red cabbage contains 18 per cent. of lime salts. Some thirty years ago patients were recommended to sleep in cowsheds, as the air of these sheds was esteemed particularly beneficial to phthisical persons. Prof. Jaccond, of Paris, obtained good results from this method.

Each year produced some new treatment for the malady. I will examine before you the most recent additions to the already interminable list of drugs, in passing over cacodylates, arrhenal and lecithine, inhalations of nitrate of thorium of Sharp-Gordon, injections of petroleum and ether of Vnoukov, paratoxine of Lemoine, all of which require confirmation. But I will insist on atoxyl, opotherapy, sea water serum, and the treatment of Ferrier.

Atoxyl was supposed to be a specific for tuberculosis, but if this agent is inoffensive when employed in small doses, it has no real action on the malady. However, M. Hallopeau seems to have obtained good effects from atoxyl in the treatment of renal tuberculosis, and concluded that it might be useful in the pneumonic form.

Lesions of the glands of internal secretion, being frequent in tuberculosis, many were led to consider the rôle of opotherapy in the disease. Leaving aside the thyroid gland, I will say a few words on the hypothesis. M. Torri (Italy) and M. Garnier (France) noted frequently lesions of this gland in tuberculous patients, and Marfau having discovered that the arterial tension was lowered in such persons, it was thought that the gland given internally might, by raising the tension, render service. But from experiments made both by myself and others, we were forced to the conclusion that if the arterial tension was raised in reality, and that the appetite improved and insomnia disappeared more or less, the administration of this organ had no influence on the progress of the malady one way or the other.

Two years ago MM. Quinton and Simon recommended for tuberculosis injections of marine serum rendered isotonic and sterilised. I treated several apyretic patients with this plasma in small doses (one or two ounces), repeated twice a week, and obtained an increase in weight and appetite, and a general bracing up of the constitution. But when I tried it on febrile patients, and, on the advice of M. Quinton, increased the dose to four and six ounces, I was positively frightened at the results. The fever rose 2 or 3 degrees, followed by depression, loss of strength, appetite and weight—in a word, all the symptoms were aggravated, and I was obliged to abandon the injections. I would not advise anyone to have recourse to injections of marine serum for any patient whose rectal temperature exceeded 100° F., and only in small doses (2 oz.) in apyretic patients once a week.

The method of M. Ferrier consists in recalcification of tuberculous patients. In 1905 M. Ferrier made known the results of this new treatment, which was based on logical facts. According to him, consumptive persons underwent a process of decalcification, and his method consisted in restoring to the organism the salts that were wanting. The idea struck me favourably, and I determined to try it both in hospital and private practice, and was convinced that it could give good results where other agents failed. The agent employed to this end was chloride of calcium in small doses. Chloride of calcium has been recommended in the treatment of pruritis, pneumonia, albuminuria, and it acts just as well in small as in large doses; consequently small doses of the salt are sufficient to obtain recalcification of the organism.

We will now speak on the specific treatment of tuberculosis by serums and tuberculins.

M. Maragliano discovered some ten years ago an active serum for tuberculosis, which he made known through various publications. At the Congress, held last year at Lyons, he presented several observations of cases treated more or less successfully by his serum. Some months ago I was called in consultation to a lady who showed signs of wasting, but without presenting any definite symptom of consumption. In order to clear up the case the diagnosis by tuberculin, according to the method of Moeller, was tried. The reaction was positive, and we concluded that the patient was tuberculous. The treatment by the serum of Maragliano was advised, and the patient gained 14 pounds in weight at the end of three months. At the end of two more months she was submitted again to the experiment of tuberculin, but this time no reaction took place. We concluded consequently that the serum had removed all trace of the malady. But in reality the lesion, if lesion there were, was insignificant and almost imperceptible to clinical examination. My colleague, M. Guinard, obtained also, in some patients, interesting results from the employ of the serum of Maragliano.

I have not, for my part, utilised the serum of Marmorek, but German, English, and French authors have borne favourable testimony to the method. M. Marmorek possessed the merit of sustaining alone his ideas, and had the rare courage to treat consumption in its advanced stages, and consequently to expose himself to failures. However, on account of accidents produced by his serum, he was obliged to modify his *modus operandi*, and to prefer rectal injections to subcutaneous injections.

According to statistics published it does not seem that this serum is superior to the preceding. But any of these serums are liable to cause accidents as soon as injected. It is thus that Dr. Guinard describes what frequently follows these injections: "In from 15 to 20 seconds after the injection of serum of the goat or of an immunised horse, and sometimes even during the injection if done very slowly, appear suddenly phenomena of general stimulation of the vaso-motor system and the involuntary muscles, with troubles of the respiration and the cardiac rhythm. The symptoms commence generally by a difficulty in breathing; the patient believes he is choking, while waves of heat pass over the face with symptoms of vertigo. The face, neck, thorax, etc., become scarlet, the eyes are injected, and the heart beats are rapid, but so weak as to be almost imperceptible; the peristaltic action of the intestines is stimulated and the contractions are painful, accompanied by a desire to go to stool. A few seconds after these first phenomena, and when the patient is beginning to feel better, symmetric white spots, due to vaso-constriction, appear on the face, the chest, under the eyes, at the corners of the nose, on the forehead, ears, etc. Gradually all these symptoms disappear and the coloration of the skin becomes normal, when perspiration sets in, sometimes accompanied with rigor and a sensation of cold, by which the series of accidents terminates.

During a few following hours the patients suffer from a slight headache, while the temperature rises suddenly in the evening to 102° or 104° F.

We will now proceed to pass in review the different tuberculins: The old tuberculin of Koch T.O., the new tuberculin T.R., that of M. Denys (Louvain), and of Beraneck (Neufchâtel).

The tuberculin T.R. was employed by many authors, and especially by the celebrated English *savant*, Wright, who introduced his method of opsonins by which the use of the tuberculin could be regulated according to the reactions produced by the organism after each injection. Wright obtained good results in local tuberculosis, but as my colleague, M. Jousset, justly said in his report to the Société d'Etudes Scientifiques sur la Tuberculose, Wright seems to have abandoned the attempt against pulmonary consumption by the tuberculin T.R. which, in his opinion, was too dangerous to handle.

We will continue this subject in our next lecture.

GERMANY.

Berlin, Jan. 5th, 1908.

At the Medical Society, Hr. Langenstein discussed the problem of the

Artificial Feeding of Infants.

The starting point of the problem was the chemical comparison of the physiological and aphysiological foods. A comparison of human and cow's milk showed the quantitive differences in albumen, sugar, and salts. As regarded the quality of the food, it was to be observed that the fat of human milk was richer in olein than that of cows, that there were fundamental differences in the albumen of the two kinds, and that cow's milk contained considerably more casein and less albumen, human milk on the other hand less casein and more albumen. Whilst the carbohydrates were essentially represented by the milk sugar, as regarded the salts, we were not acquainted with them with sufficient certainty to give the average value of each different kind of salt; at any rate, it seemed possible that human milk was subject to considerable oscillations as regarded its different salts.

The inquiry for a long time was mainly devoted to the difference in the albuminous constituents of the two kinds; clinically, only one point justified this direction, and that arose from morphological considerations. In the fæces of many children fed on cow's milk particles were seen that bore a certain resemblance to curd. The chemical analysis of these particles, their constituents of phosphorus and nitrogen confirmed the belief that they were undigested casein.

The arguments of Heubner and Czerny however were not sufficient to do away with the belief in injurious food remnants, and the hypotheses springing from a biological mode of thought that the bad effects of feeding with cow's milk was due to the albumen rather helped this notion than otherwise. Whilst albumen of its own kind was given to the infant at the breast, the one fed aphysiologically received albumen of a strange or foreign kind. These injurious effects of cow's milk were supposed not to occur when the intestinal glands of the infant were washed in the albumen of its own kind. Experimental and clinical experiences both spoke against the correctness of this theory. The most carefully carried out experiments taught us that there was no difference in the digestibility of the two kinds of albumen; so far as investigations on the using up of albumen made on the living infant were available no differences were recognizable in the different albuminous bodies of milk. Examinations of nitrogenous constituents of fæces in natural and artificial feeding gave no special results in the direction of difficult digestion of cow's milk. The power of resorption for albumen of both kinds of milk was the same in healthy children whatever kind of milk was given. In the intestines of the calf killed after the first meal of colostrum the same fragments of albuminous bodies were met with as in the intestines of the full-grown dog fed on horse-flesh. The new-born animal came into the world gifted with the same power of digestion as the adult, it brought with it pepsin and trypsin, and from the fifth month of foetal life, as the speaker had ascertained, the albuminous enzyme erepsin. Nothing remained over therefore as regarded an experimental basis for the supposed bad effects of feeding with albumen but the biologically different behaviour of different kinds of albumen. The disciples of the "injury" theory themselves confessed that the foreign principle was destroyed in the stomach.

Clinically it had been shown that in alimentary intoxications in children that were treated by fasting for 24 or 48 hours the giving of albumen at this period did no harm. It was remarkable also that even the strongest believers in the bad effects of albumen were also most energetic advocates of buttermilk feeding, a food that contained quite as much albumen as whole milk.

The prospects were more promising when attention was directed to the other two organic components of cow's milk. We might indeed say that our knowledge that the fat of cow's milk was a harmful factor in the artificial feeding of infants was a great step in advance, both from a scientific and a practical point of view. Here we had an injurious effect in the treatment of which by buttermilk signalised its triumph, but it was not by any means the panacea that it had been made out to be. The injurious effects of fat were most in evidence when we studied its action on the course of enterocatarrh.

When we turned our attention to the effects of the carbohydrates in infant feeding the problem seemed very difficult to clear up. As positive knowledge it had been shown that too much carbohydrates, whether starch or sugar, led to a form of injury that was very characteristic.

For the clearing up of the problem of artificial feeding the salts also appear to be of immense importance. L. F. Meyer's experiment, in which he gave human milk fat and human milk albumen in a vehicle of cow's milk whey, and, on the other hand, cow's milk fat and cow's milk albumen in a vehicle of human milk whey without any disturbance, disturbances being observed when the salts were given, indicated the great importance of both quantity and quality of the salts in artificial feeding, as the albumen contained in the whey and certain still unknown substances were certainly not responsible for the injurious effects observed.

It was certain that far-reaching changes were brought about in the milk by heating to a temperature of 100 C. From certain experiments made it was probable that when human milk was given in a cooked state the child would not thrive so well, but clinical experiences in hospitals for infants had not shown that more could be done in the matter of feeding with uncooked than with cooked milk.

There was no doubt that theoretical speculations and clinical experiences had led to an improvement in artificial feeding, and to more exact formularising for special indications. We had at least learned to dread foods containing fats; we must have learnt that coddling with excess of meal and sugar led to sickness and death. In the future we should not be content with these two experiences, but give due consideration to the "Katalysators" of nutrient material.

AUSTRIA.

Vienna, Jan. 5th, 1908.

Hepatic Rupture.

Foderl exhibited to the Gesellschaft a number of cases he had operated on. The first was a patient, æt. 30, who was operated on 19 hours after the accident, and confirmed the diagnosis of hepatic rupture made on his reception. On the day of operation sugar and acetone were both present in the urine, which could not be due to intra-abdominal hæmorrhage, but to the implication of the pancreas, which was also torn. The acetone disappeared after the operation, and the sugar later, when the diet was robbed of its carbohydrates. Later the dieting had no influence, and the patient remained sugar-free after taking any kind of food.

The next case was a revolver shot in the stomach. The peculiarity in this accident was the extraordinary amount of reflex contraction in the rectus muscle of the abdomen, which determined the operation twelve hours after the accident had occurred. On opening the abdomen a suffused clot of blood about the size of a five-shilling piece, with a gaping wound, was observed in the parietal peritoneum over the stomach, while the wall of the organ was quite free from any injury. In the median line, and directed towards the smaller curvature was a suffused tract penetrating the serous covering of the organ, and through which a long sound could be passed. The revolver used was a 7-metre weapon, making an imperceptible entrance over the region of the stomach, but no exit of the bullet could be discovered. The Röntgen rays were applied, and discovered the projectile lying embedded in the first lumbar vertebra. It seems that the bullet, after penetrating the abdominal wall, was deflected downwards along the rectus muscle till it reached the lumbar vertebra. This peculiar direction accounted for the abnormal contraction of that muscle.

Extirpation of the Saphena Vein.

Schnityler presented two patients on whom he had operated for acute phlebitis, both commencing in the gravid state. In the first case he removed the vein completely from Poupart's ligament to the malleolus, while in the second he only removed portions of the vein, particularly the varicose portions, thus avoiding a long wound along the leg, which gives equally good results and has a better appearance when complete. He thinks this intermittent operation in the saphena is advisable in both inflammatory and non-inflammatory varicose condition of the veins.

Haberer stated that he had a similar case which he had operated on in the same way, and obtained excellent results.

Injury to the Arteria Pulmonalis.

Sternberg demonstrated from an anatomical preparation which had died suddenly from a needle penetrating the pulmonary artery. The needle first had entered the anterior wall of the pericardium, and thence made its way to the posterior surface, where it penetrated the pulmonary artery. The absence of any healing of wounds in the pericardium or artery proved that the fatal injury occurred immediately before death.

Club Foot Therapy.

Semeleder treated the members to another rehearsal of his special treatment of club foot with a peculiar shoe which he has introduced for this purpose. At the very outset he condemned forced "Redressment," as it often produced another deformity in the form of flat foot, or a return in a short time to the equinus state. He next demonstrated his own method, which is a modification of tenotomy with the subsequent application of an apparatus or "shoe," as he calls it, whereby the weight of the body corrects the deformity.

By this means he contends that the paralysed groups of muscles are awakened, and the whole limb strengthened by the over-contractile muscles being relieved. Reiner could not agree with Semeleder in this "model" cure of the deformity, nor could he believe that the equinus could be so easily transformed to the valgus.

He thought the treatment with Semeleder's "shoe" was a failure, because it did not provide for adduction and inflexion.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Edinburgh Royal Infirmary.—The annual report of the Infirmary, which has just been issued, shows that during the year ending September 30th, 1907, 11,140 in-patients were treated, a decrease of 76 as against the previous year. The average daily number of patients was 832, and the average duration of treatment 27.3 days. The deaths within 48 hours of admission numbered 191; the percentage mortality, deducting these, was 5.69; including them, 7.31. The out-patients numbered 38,660. The total ordinary income was £35,707, being £2,012 more than last year. The managers' last report mentioned the appointment of an organising secretary, and they are glad to say that the results already attained through that official's efforts are most satisfactory. A regular system of periodical collecting in mines, factories, etc., has been successfully introduced, resulting in an increase of £284 on the Edinburgh collections, and of £1,016 on those in the country districts. The ordinary expenditure amounted to £33,479, an increase of £1,362, accounted for by the higher cost of articles of maintenance, coal, etc. The entire ordinary expenditure per occupied bed was £64 5s. 6½d., an increase of £2 3s. 2½d. on 1906. The increase was entirely on maintenance, medical expenditure having diminished by 6s. 7½d. The legacies and donations of £100 and upwards have reached £35,125; and the extraordinary expenditure on drainage, new surgical out-patient theatre, etc., has been £11,436. The managers then refer to the Royal visit, when T.R.H. the Prince and Princess of Wales were conducted through the hospital; to the retirement of Miss Spencer from the position of Lady Superintendent after 30 years' service, and to the appointment of Miss Gill as her successor. The average number of nurses and probationers was 245.4; the number of applications still far exceeds the number of vacancies, but has been somewhat reduced by the deterring but beneficial results of the preliminary examination. In addition to the drainage, the chief new works undertaken during the year have been the reconstruction of the surgical theatres attached to wards 16 and 17, and wards 10, 11 and 12. It is intended during the ensuing twelve months to reconstruct the medical out-patient department, which is not equal to modern requirements. During the year the managers took leave, with deep regret, of Mr. C. W. McGillivray, one of the acting surgeons, and of Dr. Alexander James, one of the acting physicians. As a testimony of their esteem for them, the managers have appointed Drs. McGillivray and James members of the consulting staff. The managers further record their regret at losing the services on the board of Dr. Affleck and Professor C. Hunter Stewart, whose term of office expires, and of Dr. Underhill and Mr. Carter, who do not desire re-election. Since the report was written the managers have to record, with deep regret, the loss by death within a day of each other of two members of the surgical staff, Professor Annandale and Sir Patrick Heron Watson. They allude in suitable terms to the eminent services rendered to the institution by these two distinguished men. Sir Patrick Watson's services were so notable and highly appreciated that on the expiry of his term of office the managers appointed him for a period of five years an extra-surgeon to the institution.

BELFAST.

Training of Nurses at the Union Infirmary and Hospital.—An interesting discussion took place at the Belfast Board of Guardians last week, when, by a large majority, the Board adopted a new scheme for the training of their nurses, as recommended by the Infirmary Committee. Under the new scheme the training will extend over four weeks, instead of three, as at present, and the period devoted to training in fever wards will be extended to six months. The actual cost of nursing last year was £6,128. there being 1,689 sick poor under the care of the Guardians in their various hospitals. It is estimated that the cost under the new scheme may be increased to about £7,150, with greater efficiency. The new arrangement seems, from all points, to be a good one, for the nurses from the Belfast Union go all over Ulster as charge nurses in the smaller Unions, and a thorough training is most desirable.

Public Health.—The High Death-Rate.—At the monthly meeting of the Corporation, held last week, Dr. Kink-Kerr, the Chairman of the Public Health Committee, attempted to explain the excessive death-rate which has characterised the returns from Belfast for many weeks now, giving it generally the unpleasant prominence of the most unhealthy large city in the United Kingdom. The explanation given was that the bad weather had caused an excessive amount of chest affections, and had also caused great mortality among the children suffering from measles, an epidemic of which now prevails. Another reason adduced is that the population of the city is really greater than the estimate of the Registrar-General, on which the rate is based. But all these circumstances are not sufficient to satisfy the citizens that all is right with the Public Health Department when we groan under a death-rate of 25.5 per 1,000, and the report of the late Commission upon the health of the city is eagerly awaited.

LETTERS TO THE EDITOR.

INHERITED SYPHILIS.

To the Editor of The Medical Press and Circular.

Sir,—Mr. R. Clement Lucas's address, printed in your issue of this week, forms a very valuable contribution to the discussion of this question. It is particularly interesting to me for the reason that clinical observation led me, long years ago, to protest against the common exaggeration of the danger of syphilitic fathers begetting tainted progeny. I find from my note-book that I made such a protest at least as far back as March 24th, 1897, when a letter from me was published in your paper of that date. Further experience, including observation of children in hospital practice, has confirmed my views. My experience would support Mr. Lucas's view, that "for transmission of syphilis it is necessary that the woman be first infected." It is almost impossible on any other grounds to explain the facts, or at least the facts which clinical experience has brought before me. My experience has been that a syphilitic father, whether he has been treated or not, seldom if ever begets tainted offspring after disappearance of secondary symptoms, say, two years after primary infection, and that after four years the danger is twice as remote. With properly carried out mercurial treatment during the first two years, the danger of producing infected children is very small, and after a further interval of two years with treatment, it can be barely said to exist. The number of children presenting unequivocal signs of syphilis among the progeny of undoubtedly infected parents is very small, and much smaller when the father alone carries the taint. Syphilis is responsible for so much unhappiness that it would be well if some portion could be reduced by a less pessimistic prognosis than is often given to young men contemplating matrimony. They can often be assured that after a sufficient lapse of time and steady perseverance throughout in treatment by mercury and potassium iodide, the danger of conveying disease to wife or child is so small as to be insignificant.

I am, Sir, yours truly,
An Average Practitioner.

January 2nd, 1908.

THE FEEDING OF SCHOOL CHILDREN.

To the Editor of The Medical Press and Circular.

Sir,—Although not written there, it is evident, from the impartial manner in which your correspondence columns are kept open for the expression of different opinions that the motto, "Audi alteram partem," really dominates them, and I am certain you will allow me very briefly to express my dissent from the reasoning in your leader under the above heading this week. The appearance of underfed children at school is merely one superficial symptom of grave social maladies; and these maladies are certainly not to be cured, and will be probably aggravated, by any measures save such as go straight to the true prime causes. And in the first place, I would remark that a great proportion of the children who are ill-nourished and look underfed are really suffering from damaged constitutions due to improper food and feeding in infancy—often from the mother's inability to suckle them. Many are underfed because the mothers are entirely ignorant of the art of cooking. They know nothing about food materials and the proper way of preparing them. The English poor throw away or neglect to use cheap foodstuffs which foreigners, French and Germans, to a great extent live upon; and very few English wives know how to prepare oatmeal porridge or any of the cereals which are almost enough alone for the nourishment of children. Not one in a thousand understands the making of soup from bones, and the thickening of it by potato, rice, or bread into an appetising and nourishing food. By taking away the incentive to learn housewifery, and by putting a premium on ignorance by the public feeding of the children, a vast amount of harm will be done. Those mothers who make a sacrifice and try to do their duty to their children will be made worse off than the thriftless and improvident. Then where do the rates come from to pay for the feeding? Out of the pockets of many citizens not more able to afford the impost than those upon whom it is expended. And, again, the thousands of pounds thus expended are taken from funds which would otherwise be used in employing labour, and for every few hundred children fed a certain number of workmen will have their employment curtailed or taken away. These are only a few of the facts which should be considered in problems like that in hand. If children are sent to school underfed, every case should be inquired into. If the parents are carelessly neglecting their duty, they ought to be prosecuted; if they are destitute the Poor-law or charity should deal with them. The crude Socialistic experiments based upon expediency, which ignore economic and scientific facts, and which are now the fashion, will, if carried far enough, lead to the moral and material ruin of the State.

I am, Sir, yours truly,

Medical Economist.

Christmas. 1907.

THE *STAR* AND THE MEDICAL PROFESSION.

To the Editor of The Medical Press and Circular.

Sir,—Unsigned letters in the lay Press from members of the profession have little weight, and there exist more than enough reasons why one cannot publish one's name in papers like the *Star*. Would you allow me to put the following query to the Editor of your contemporary, through your valuable journal, and at the same time vouch for my good faith and professional position? I wish to ask him how he accounts for the fact that, with the exception, perhaps, of the extremely rare instances in which a medical man is an anti-vaccinationist, the whole of the profession take care that their own children are vaccinated? Does he believe that a man, when he becomes a doctor, is converted into an anti-human monster capable of sacrificing his own children in a vile conspiracy for paltry, sordid gain? Does he not see that if the profession—not only in these islands, but throughout the civilised world—have the operation carried out on those they love, it must be because they, as an army of skilled witnesses, are satisfied that at least vaccination is a perfectly harmless process?

I am, Sir, yours truly,

A Surrey Doctor.

Near Reigate, January 3rd, 1908.

[We have received for publication a number of letters which have passed between Mr. G. W. F. Robbins, Secretary of the National Anti-Vivisection Hospital, and the Hon. Sydney Holland, on the subject of the equipment of the hospital in question. As the correspondence is far too long for insertion in our columns in their present crowded state, we refrain from commenting upon it. Probably some of the dailies will be able to give it space.—Ed. M. P. and C.]

A case of suspected cholera has occurred in a suburb of Constantinople. The victim, a Greek, died on Friday.

OBITUARY.

ROSS JORDAN, M.R.C.S., L.S.A.

We record with sorrow the death, which took place on January 2nd, of Mr. Ross Jordan, of Birmingham. For some time past Mr. Ross Jordan had not been in the best of health, and early in November he had an acute attack of pneumonia. From this he apparently recovered, but early in the year he was not so well, and he unexpectedly died in his sleep. At Queen's College Mr. Ross Jordan received his early medical education, but a suitable opportunity occurring for his entry into a merchant's office at Bradford, he spent three years in the service of a mercantile firm. At the end of three years family arrangements required his re-entry into the medical profession, and, returning to Birmingham, he rejoined Queen's College and resumed his studies there. He qualified for practice as M.R.C.S. and L.S.A., and commenced to practise in Birmingham. In 1868 and 1869 Mr. Ross Jordan and three friends—Drs. George Jones, James Neal, and Lumley Earle—became convinced of the necessity for a hospital to be entirely devoted to the alleviation of cases peculiar to women. The effort was at first unsuccessful, but at last Mr. Ross Jordan succeeded in enlisting the interest of Mr. Arthur Chamberlain, who undertook the duties of honorary secretary, and with the aid and support of a number of gentlemen—amongst others Mr. Joseph Chamberlain and the late Dr. Heslop, George Dawson, Arthur Ryland, Charles Vince, Dr. Samuel Berry, and Joseph Nettlefold—in 1871 the Birmingham and Midland Hospital for Women became an accomplished fact. The hospital was first opened in the Crescent, but the out-patients' department was transferred to the Upper Priory in October, and the in-patients' department to Sparkhill in the December of that year.

Of the hospital Mr. Ross Jordan was regarded somewhat in the light of the founder. His peculiar knowledge and ability in women's cases were employed in its interest during its early years, and until an unfortunate illness in 1880. After this he continued to render it valuable service as consulting surgeon. His connection with the hospital was maintained from its inception, and in many ways he was able to aid by his abilities the institution and its patients. He was regarded by the entire staff with the greatest esteem and respect, and with the kindliest of kindly feelings.

HENRY ALCOCK DIXON, M.R.C.S.

We regret to announce the death on December 24th of Dr. Henry Alcock Dixon, of Burnley. Dr. Dixon was a Burnley man, the son of Mr. John Alcock Dixon, solicitor. Dr. Dixon was educated at the Burnley Grammar School, afterwards at Rossall College and Stonyhurst College, and subsequently was apprenticed for seven years at the Royal Infirmary, Manchester, being the last senior apprentice that institution had. He then qualified as a member of the Royal College of Surgeons, and commenced practice in Burnley. Dr. Dixon, who had a large practice, was highly respected, and his reputation was greatly enhanced by his unflinching devotion to smallpox patients during the epidemic in the Kirkgate district. Some years ago Dr. Dixon had a severe illness, and this being followed by another, he lost the sight of his left eye.

SPECIAL ARTICLES.

THE TEACHING OF MIDWIFERY IN IRELAND.

We publish in our present issue a report of a most important discussion, which took place at the Obstetrical Section of the Royal Academy of Medicine in Ireland, on the recommendations suggested by the General Medical Council with regard to the teaching of midwifery. We also publish in full the address with which the discussion was opened by Sir William Smyly. The recommendations of the Medical Council may be briefly stated as follows:—Students before commencing the study of practical midwifery must have attended lectures on surgery and midwifery, and have held the post of surgical dresser and medical clinical clerk. They must then attend the indoor practice of a lying-in hospital for three months, and after having received instruction in the conduct of labour, must conduct twenty cases of labour. Further, the Medical Council suggests that clinical examinations in midwifery ought to be held by the licensing bodies. These recommendations constitute an enormous advance on the present state of affairs as it exists in Great Britain. As an instance of the extent of that advance, it may be mentioned that, at the present time, certain licensing bodies only require the student to attend six cases of labour, and after this he is considered to be qualified to attend all normal and abnormal labours. In Ireland, on the other hand, these proposals constitute in one important particular a retrogression, because, in Ireland, the licensing bodies have united to demand a six months' course of attendance at a recognised maternity hospital. If the recommendations of the Medical Council are adopted *in extenso*, this course will be reduced to three months, and, although certain benefits will result from the adoption of the other recommendations, they will by no means counterbalance the injury done by the shortening of the course of practical instruction. It is, therefore, not surprising to find that at a meeting at which were present almost all the leading Dublin obstetricians, a resolution was unanimously carried, which, while recognising the great advance the recommendations of the General Medical Council would effect over the existing state of things, condemned as undesirable and impracticable the substitution of a three months for a six months' course by the Irish licensing bodies. We understand that those who are in favour of the alteration in the length of the course of instruction, base their opinions on the facts that students, as a body, do not continue to attend the maternity hospital after they have taken out the necessary number of cases. This is a fact, and it is a fact which calls for the serious attention of the licensing bodies, because it is due to the failure of their regulations to lay down explicitly what is expected from the student. It is impossible for the hospital authorities to force on a student more than the licensing bodies require from him, but once the licensing bodies definitely specify their requirements, we are sure that the hospitals will be only too pleased to insist on compliance with them. For this reason we welcome the further paragraph in the resolution adopted by the Obstetrical Section of the Academy of Medicine, calling on the licensing bodies to insist on regular attendance at clinical instruction in the hospitals as well as on the conduction of 20 cases of labour. If the course recommended by the Dublin obstetricians is adopted by the licensing bodies in Ireland, the high position and reputation of the Irish obstetrical school will be maintained. If, on the other hand, the present effort to raise the standard of obstetrical training in Great Britain results in a lowering of the standard in Ireland, the result will be in the highest degree prejudicial to the reputation of the Irish school and to the obstetrical training of the future Irish medical student.

REVIEWS OF BOOKS.

BOOK OF PRESCRIPTIONS (a).

"BEASLEY'S PRESCRIPTIONS" is an old friend to many generations of practitioners, and in its new form, re-written by Mr. E. W. Lucas, it is bound to have many readers. The book, of course, is little more than a compilation, as have been the previous editions, and that, we fancy, is a great advantage, for when a pharmacist, however accomplished, seeks to indicate the uses of drugs, it is not long before he fails. For instance, even Mr. Lucas himself, when he is tempted to step from his last, tells us that sulphonal "is absorbed so slowly that it takes some hours to act," which is what we were all told ten years ago, and which patients have disproved for us over and over again. So, too, in the next paragraph, he says rather abruptly of trional, "No use when there is acute pain"—another far too sweeping an assertion. But in the general course of the book we find the author painstaking and trustworthy, and the prescriptions are not only, as far as we can see, quite accurate, but varied, well chosen, and useful. To the student who wishes to learn to prescribe, and to the practitioner who wishes to keep himself *au fait* with the art, we can recommend their perusal, for there is much that is suggestive and helpful, and it is a great thing nowadays to be able to give elegant mixtures to patients without resorting to some preparation manufactured by an enterprising firm who are unacquainted with the particular patient's needs. The doses are all given according to both the imperial and metric systems, and we think the author is wise in having adopted the approximate equivalents—viz., 30 cc. for an ounce, and .06 gramme for a grain—rather than plunge into pedantic morasses of exactitude. Altogether the new edition of this old favourite promises well to maintain the popularity of the work, and when we have the pleasure of reviewing the tenth edition, we trust that we shall not find in it the second prescription on p. 110—at any rate under the same description as at present.

ORGANIC CHEMISTRY. (a)

THE authors of text-books on organic chemistry are usually enthusiasts to whom the mass of formulæ and hard facts have a strong attraction, and their efforts in writing are generally of a harsh and uninviting nature that renders the subject repulsive to the medical student. As a striking contrast to such volumes we welcome the work under consideration, which, while being thoroughly in line with modern work, places the matter in as attractive a manner as possible, thus causing the student to acquire an interest in the subject. As the requirements of the English examining bodies are greater than those required by German ones, the translator has made the necessary additions to the text, which include an appendix on practical methods. The chapter on proteins is of peculiar value as the recent work of Emil Fischer is referred to, while the nomenclature of these bodies is that recommended by the Physiological and Chemical Societies. The book reflects considerable credit on both the author and translator.

NEW BOOKS AND NEW EDITIONS.

THE following have been received for review since the publication of our last monthly list:—

FELIX ALCAN (Paris).
- Le Ventre II. l'Estomac et l'Intestin. Par Dr. F. Cantru et Dr. M. Bourcart. Pp. 335.

BAILLIERE, TINDALL AND COX (London).
- Aids to Pathology. By Harry Campbell, M.D.Lond. Illustrated. Pp. 184. Price, cloth 3s. 6d. net, paper 3s. net.
- The Hair and its Diseases, including Ringworm, Greyness and Baldness: an Introductory Handbook. By David Walsh, M.D.Edin. Second Edition. Illustrated. Pp. 94. Price 2s. 6d. net.
- Medical Laboratory Methods and Tests. By Herbert French, M.A., M.D., F.R.C.P.Lond. Second Edition. Pp. 175. Price 5s. net.

CHAPMAN AND HALL, LTD. (London).
- A Text-Book of Organic Chemistry. By A. F. Holleman, Ph.D., F.R.A.Amst. Translated from the Third Dutch Edition by A. Jamieson Walker, Ph.D., B.A., and Owen E. Mott, Ph.D. Second English Edition, re-written. Pp. 589. Price 10s. 6d.

CHURCHILL J. AND A. (London).
- The Borderland of Epilepsy. By Sir William R. Gowers, M.D.Lond., F.R.S. Pp. 121. Price 4s. 6d. net.
- Year-Book of Pharmacy, 1906-7: with the Transactions of the British Pharmaceutical Conference at Manchester, July, 1907. Edited by J. O. Braithwaite, E. Saville Peck, M.A., and Edmund White, B.Sc., F.I.C. Pp. 549. Price 10s.

THE CLARENDON PRESS (Oxford).
- The Quarterly Journal of Medicine. Edited by Wm. Osler, J. R. Bradford, R. Hutchison, etc. Volume I., No. 2. January, 1908. Pp. 223. Price 8s. 6d. net.

(a) "The Book of Prescriptions." Rewritten by E. W. Lucas, F.I.C., F.C.S., Late Examiner of the Pharmaceutical Society of Great Britain. Introduction by Arthur Latham, M.A., M.D., F.R.C.P. Ninth Edition. London: J. and A. Churchill.

(a) "Text-Book of Organic Chemistry for Medical Students." By Dr. G. v. Bunge, Professor of Physiological Chemistry in the University of Basel. Translated with additions by R. H. Aders Plimmer, D.Sc.Lond., Assistant Professor of Physiological Chemistry, University College, London. Pp. 260 and ix. London: Longmans, Green and Co. 1907. Price 6s. net.

Archibald Constable and Co., Ltd. (London).
  The Essentials of Cytology. By Chas. E. Walker, with a Preface by Prof. C. S. Sherrington, F.R.S. Pp. 139. Price 7s. 6d. net.
Unione Co-Operativa Editrice (Rome).
  The Hygiology of Rome and Rome as a Health Resort. By John J. Eyre, M.R.C.S., L.R.C.S.P., D.P.H.Camb. Reprinted from "The Seven Hills Magazine," March, 1907. Pp. 23.
Wm. Green and Sons (Edinburgh).
  Arterial Hypertonus, Sclerosis and Blood-Pressure. By Wm. Russell, M.D., F.R.C.P.Edin. Illustrated. Pp. 194. Price 7s. 6d. net.
H. K. Lewis (London).
  Injuries to the Eyes of the Employed and the Workmen's Compensation Act: Problems in Prognosis. By W. M. Beaumont, Surgeon to the Bath Eye Infirmary. Pp. 160. Price 5s.
  The Opsonic Method of Treatment. By R. W. Allen, M.B., B.S. Pp. 138. Price 5s. net.
  A Guide to the Administration of Ethyl Chloride. By G. A. H. Barton, M.D. Second Edition. Pp. 54. Price 2s.
London Homœopathic Publishing Co. (London).
  Thomas Skinner, M.D. A Biographical Sketch. By John H. Clarke. Pp. 93.
Longmans, Green and Co. (London).
  The King's College Hospital Book of Cooking Recipes. Being a Collection of Recipes contributed by friends of the Hospital in aid of the Removal Fund. Pp. 272. Price 1s. net.
  Movable Kidney and Other Displacements and Malformations. By David Newman, M.D., F.F.P.S.G. Pp. 233. Price 5s. net.
  Transactions of the Clinical Society of London. Volume XIV. Pp. 295.
  Proceedings of the Royal Society of Medicine. Volume I., No. 1. Price 7s. 6d. net.
  Comparative Electro-Physiology. By Prof. J. C. Bose, M.A., D.Sc. Illustrated. Pp. 760. Price 15s. net.
Macmillan and Co., Ltd. (London)
  Primary Nursing Technique for First-Year Pupil Nurses. By Isabel McIsaac. Pp. 197. Price 3s. net.
Associated Newspapers, Ltd. (London).
  The "Daily Mail" Year Book for 1908. Edited by Percy L. Parker. Pp. 269. Price 6d. net.
Young J. Pentland (Edinburgh).
  The Edinburgh Medical Journal. Edited by Alexis Thomson, M.D., F.R.C.S.Edin., and Harvey Littlejohn, M.B., F.R.C.S. Edin. New Series. Volume XXII. Pp. 564.
Rebman, Ltd. (London).
  Hygiene of the Lung in Health and Disease. By Prof. Dr. L. von Schrotter. Translated by H. W. Armit, M.R.C.S., L.R.C.P. Illustrated. Pp. 135. Price 2s. net
  A Manual of Surgery. By Francis T. Stewart, M.D. Illustrated. Pp. 778. Price 15s. net.
  Lateral Curvature of the Spine and Round Shoulders. By R. W. Lovett, M.D. Illustrated. Pp. 188. Price 7s. 6d. net.
  Retinoscopy (or Shadow Test). By James Thorington, A.M., M.D. Fifth Edition, revised, enlarged and illustrated. Pp. 67. Price 4s. 6d. net.
Sands and Co. (London).
  The Nurse's Day and Night Report Book. Price 6s. net.
W. B. Saunders Co. (Philadelphia).
  The Pancreas: its Surgery and Pathology. By A. W. Mayo Robson, D.Sc., F.R.C.S., and P. J. Gammidge, M.B., D.P.H. Illustrated. Pp. 546. Price 21s. net.
  Diseases of the Genito-Urinary Organs and the Kidney. By R. H. Greene, A.M., M.D., and H. Brooks, M.D. Illustrated. Pp. 536. Price 21s. net.
Sherratt and Hughes (Manchester).
  A Plea for Establishing Municipal Maternity Homes for Cases of Abnormal Labour and Puerperal Fever. By Sir Wm. J. Sinclair, M.D. Pp. 97. Price 3d.
John Wright and Co. (Bristol).
  Precious Stones for Curative Wear: and other Remedial Uses: likewise the Nobler Metals. By W. T. Fernie, M.D. Pp. 486. Price 6s.
  An Index of Treatment by Various Writers. Edited by Robert Hutchison, M.D., F.R.C.P., and H. Stansfield Collier, F.R.C.S. Pp. 877. Price 21s. net.

LITERARY NOTES.

We have reason to believe that, before many months of the New Year have passed, the two medical journals, the *Edinburgh Medical Journal* and the *Scottish Medical Journal*, will be amalgamated. Rumour has it that the support accorded by the profession in Scotland has not been sufficient to maintain the two in healthy rivalry, and that one of these must necessarily "go to the wall."

⁂

One of the events of the year now closed was the retirement in December of Mr. Pentland, of Edinburgh, from the medical publishing business, and the disposal of his stock and copyrights to Mr. Froude and Messrs Hodder and Stoughton, hitherto publishers of religious works. It is matter for congratulation that, at least on the present occasion, "medicine has not gone to the dogs," but to the angels.

Another journalistic change to chronicle is the incorporation of *The Health Resort* with *The World of Travel* with the opening of the New Year. The former, which has changed hands more than once during its brief career, now ceases to exist as a distinct entity. The first number of the amalgamated journals is before us, and appears to be conducted on similar lines, the only notable feature being its altered title.

⁂

The first volume of the *Dublin University Calendar* for 1907-8 has recently appeared. It contains the usual information as to the ordinary and Honours courses in Arts and in the professional schools, together with the ordinary papers set in the year 1906-1907. The volume, therefore, is specially the book for information for students. Its contents are arranged in fairly accessible manner, and we have detected very few blunders.

⁂

This excellent publication ("Hazell's Annual") lies on our library table, with all the comely importance that can be assumed by a standard reference book in the twenty-third year of its issue. The familiar arrangement of sections is again adopted, and the usual multitudinous array of facts and figures is contained between its handsome red covers. Our readers cannot do better than buy a copy of this useful book for their library table. It is a veritable storehouse of facts garnered with untiring industry from many devious fields of human activity.

⁂

Two excellent diaries and note-books have come to hand for 1908. One is "The Consultant's Appointment Book," issued by Messrs. Burroughs, Wellcome and Co., which, we believe, has been presented gratuitously to the majority of the profession, and which appears to have taken the place formerly held by "The Visiting List." The other is "The Doctor's Diary and Emergency Note-Book," a smaller publication, as its title indicates, and this has also, we understand, been very freely presented to members of the profession by Messrs. Scott and Bowne. Both are elegantly bound in leather, and will be found extremely useful pocket companions during the New Year on which we have now entered.

⁂

The course of lectures that Miss Kanthack delivered last year to the voluntary health visitors in St. Pancras on "The Preservation of Infant Life" have been published in book form by Messrs. H. K. Lewis (price 1s. net), and form an excellent guide to ladies undertaking such work. Properly organised and with suitable visitors, this work forms a desirable portion of the scheme for reducing infant mortality, and Miss Kanthack's experience of the matter allows her to speak with experience. We are glad to notice the constant emphasis laid on the necessity for invoking medical skill, and the reprehensibility of the visitor tendering medical advice.

⁂

Herbert Fry's Royal Guide to the London Charities makes its forty-fourth appearance this year, and is as welcome as ever. To medical men, especially those in the metropolis, it is invaluable, as at a glance they can refer this, that, or the other broken-down wayfarer to the proper channel for relief. To those not acquainted with Fry's Charities the number of eleemosynary societies and institutions existing in London will furnish a surprise. Nor are the objects for which many of them exist less astonishing, and the juxtaposition which alphabetical arrangement connives at produces some incongruous results. For instance, the "gentlewomen of high moral character, in reduced circumstances" benefiting from the "Annuitants Homes" find themself check by jowl with the Anti-gambling League, and the Clapham Maternity Hospital adorns the same page as "Becker's Bounty for Poor Pious Clergymen." We cannot help being struck with the immense number of charitable institutions served gratuitously by medical men, and the fact that only two societies exist for the benefit of them or their widows.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT SURGICAL LITERATURE.

Cholecystitis with Gangrene of the Gall Bladder.—Ross (*Canadian Practitioner and Review*, Dec., 1907) reports five cases of gangrene of the gall bladder. In each case the patient was operated on, and the gall bladder opened and drained, with successful results. The author says: "I find that the symptoms of the disease are of a very marked type. The patient, perhaps in the midst of health, is seized with a sudden acute pain in the right hypochrondrium, which may be so severe as to cause collapse, faintness, and prostration. The most peculiar symptom I have observed is the condition of the pulse, the rate of which varies very quickly from 70 beats to the minute to 130 to 140 to the minute, when it becomes feeble and running, and is accompanied by lividity of the face, blueness of the hands and feet. There is always an elevation of temperature, and sometimes a rigor. When such a condition is present, and a mass is found in the right hypochondrium, beneath the edge of the liver, extremely sensitive to the touch, we are justified in diagnosing gangrenous cholecystitis, and immediate operation is indicated. By early operation and open drainage, I have been able to save 100 per cent. of my cases." S.

The String-cutting Method of Treatment for Impermeable Œsophageal Strictures.—Abbe (*Med. Record*, Nov. 30th, 1907) reports a case which he treated successfully fifteen years ago for the above condition, following the accidental swallowing of caustic. Since then the author has tested the œsophagus once a year, and there has never been the least recurrence of stricture. At the time of the operation only fluids could pass the stricture, and the amount of food that could be swallowed was growing daily less. The smallest filiformed bougie would not pass through the stricture from the mouth. The stomach was opened and stitched to the abdominal wall. Guided by the index finger, a long filiform whalebone bougie was passed from the stomach to the mouth, though impassable from above downwards. To the end of this a string was tied and pulled up through the œsophagus. To its lower end a Billroth dilating bougie was tied, and drawn up till it engaged the stricture. As it would not pass through, it was withdrawn temporarily, and an extra string drawn up, and again the bougie pulled tightly into the stricture. By pulling the second string backwards and forwards, while the wedge-like end of the bougie was tightly crowded into the stricture, it was felt that the bougie passed rapidly up. Larger ones were immediately substituted, and under their stretching the stricture quickly melted away before the string friction. With almost no bleeding the largest bougie passed entirely from stomach to mouth. The gastric fistula was closed after two weeks. The largest bougies were passed every few days at first, and later at longer intervals. In 1904, the author treated a child of three years in the same way for a similar condition. When the gastric fistula was closed dilatation was continued for some time. In the course of months, however, omission to continue this treatment faithfully led to partial closure, although swallowing of soft food continued. As it was not desirable to open the stomach again, the author devised a dilating metal guide which carried a string down to the face of the stricture and back again, so that, working entirely from the patient's mouth, the stricture could be worn through on the same principle. The *technique* is as follows:—An assistant holds the head back, and the instrument is pushed down the straight œsophagus until the probe-ending guide engages in the stricture, and the metal shoulder bears hard against it. While the operator forces the instrument onwards, a third assistant pulls the string backwards and forwards, and wears away the cicatrix where the string presses against it. It is thus impossible for the instrument to go astray from the canal, which widens as it advances, and harmful perforation, the author claims, cannot occur. In the above case, with more frequent dilatation during the ensuing year, no more trouble followed. The child is now able to eat everything, and is in robust health. In summarising, the author says—(1) Most obstructive cicatricial œsophageal strictures can be dilated from above, and should be so treated. (2) Those which are only permeable by a fine bougie offer great chance of serious perforation of the walls of the tube during dilatation where much force is required to push it through. (3) Those that admit a probe of some size can be safely cut from above by the string-cutting œsophagotome. (4) Very tight and impermeable ones can always be safely, quickly, and permanently cured by gastrotomy, followed by string-cutting. S.

Primary Sarcoma of the Vermiform Appendix.—Carwardine (*Brit. Med. Journ.*, Dec. 21st, 1907) reports a case in which this rare condition was found. There are only two other recorded cases. The patient was a lady, æt. 45, who had suffered from colicky pain for five months. Tenderness then appeared, and a deep-seated swelling was found, occupying the false pelvis. On operation the appendix was found to be 3½ inches long, as big as one's thumb, and very hard and very adherent. It was enucleated with considerable difficulty, and fractured like a carrot near the base. The cæcum and ileum were normal. The base of the appendix presented into the cæcum like an os uteri. Microscopic sections showed the appendix to be uniformly composed of round cells. The pathological changes involved the whole of the wall between the peritoneum and the musculares mucosæ. The growth was regarded to be a lympho-sarcoma having its primary origin in the submucous tissue. S.

Removal of a Lump of Wax from the Bladder by Benzin.—Lohnstein (*Berlin Klin. Woch.*, July) reports the case of a workman, æt. 23, admitted to hospital with cystitis and hæmaturia which had been going on for over three months without any apparent cause. The urine was turbid, and contained clumps of bacteria. Cystoscopy showed a yellowish white mass attached to the vertex of the bladder. At first this was believed to be a ligature encrusted with salts, but as no operation had been performed on the patient this was obviously incorrect. The introduction of any foreign body per urethram was denied. Repeated cystoscopic examinations showed that this white mass was not attached to the wall of the bladder, but only kept its place in the vertex of the bladder because it floated up to the top of the fluid in the bladder. The only possible substances that would do this were wood, cork, or wax. As it would have been impossible to introduce an object so large into the bladder per urethram if made of cork or wood, it seemed certain that the foreign body was a lump of wax. On being told that he had wax in his bladder, the man then admitted that six months previously, owing to severe itching in his urethra, he had broken off a piece of candle and moulded it so that it could pass into his urethra, and only a small portion of this escaped externally. As the surface of the wax had not become encrusted with salts, it seemed possible to dissolve it with benzin. After emptying the bladder, 15 c.c. of benzin were injected into the organ, and as no painful symptoms followed, the fluid was allowed to remain for 40 minutes, when it was withdrawn by a catheter. Another injection of 25 c.c. of benzin was given, but this almost at once caused pain, and the patient felt as if he had been drinking spirits, so the benzin was withdrawn at once. By evaporation rather more than 5 gm of solid stearin was obtained; the third time the bladder was washed out the benzin returned pure, without any trace of wax. Cystoscopic examination showed no foreign body, and the bladder walls only slightly hyperæmic. The urine soon became normal, and the patient was discharged cured. Bergmann and Rothschild have reported similar cases. G.

Palliative Operations for Cancer of the Bladder.—Cabot (*American Journ. of Urology*, Sept., 1907) reports several cases of cancer of the bladder in which palliative operations had been performed, and after considering the subject fully, comes to the following conclusions:—(1) That palliative operation is of value in cases of cancer of the bladder; (2) that in properly selected cases operation will prolong comfortable existence very materially; (3) that suprapubic drainage of the bladder will relieve the symptoms and promote the comfort of patients for whom nothing more radical can be done; (4) that hæmorrhage should not be allowed to continue unchecked unless efficient examination has shown that the cause cannot be removed by any form of operation. G.

Non-Operative Treatment of Stricture.—Begg (*Post-graduate*, Dec., 1907) gives a very full account of strictures of the urethra, and pleads for a more thorough trial of the non-operative means of treating such cases. He believes that no stricture should be cut until dilatation has been first attempted. Few strictures need to be cut, and urethrotomy should only be resorted to when the stricture is undilatable or where an emergency demands immediate bladder drainage. The writer does not believe that internal or external urethrotomy should never be performed; there are certain cases where it is obligatory. The type of stricture in which it is undesirable to attempt dilatation, and in which either internal or external urethrotomy are indicated are strictures at or within one inch of the meatus. In hard, fibrous strictures which are practically undilatable, again in resilient strictures which contract as soon as dilated, strictures behind which an extravasation of urine has occurred, should be dealt with at once by a cutting operation, strictures complicated by severe cystitis, so that drainage of the bladder becomes necessary, and, lastly, in cases of stricture complicated by renal or pelvic inflammation. G.

The Local and Internal Treatment of Gonorrhœa.—Prof. Neisser (*Medizinische Klinik*, No. 14, 1907) regards the local measures as of the most importance in cases of gonorrhœa. He prefers injections to irrigations, for the latter require too much time and special attention, and cannot be therefore used in all cases. If the patient be provided with a proper injection and a suitable syringe, and, further, be carefully instructed in their use, they are entirely harmless in all but most exceptional cases. Prof. Neisser admits that the injection treatment is neither ideal nor simple; he does not believe that the use of balsams alone is sufficient to cure gonorrhœa, but says that they are a valuable adjunct to local measures. They relieve the distressing symptoms due to the irritation of the mucous membrane, and so render more efficient local measures used during the early stages of the disease. The author believes that gonosan is the best form in which to administer the balsams. It is the most effective preparation in allaying the irritation and preventing painful erections. Even where vesical inflammation is present, gonosan acts as a sedative to the nerves of the bladder, and at once relieves the annoying dysuria. The opinion expressed by a large number of observers that gonosan, given internally, is sufficient to cure gonorrhœa, without the aid of local measures, is opposed by Neisser. He admits that in isolated instances this may occur. His contention is based on the assumption that none of the balsamics, including gonosan, is capable either of destroying the gonococcus or of affecting its growth. G.

MEDICAL NEWS IN BRIEF.

Birmingham Sanatorium for Consumptives.

THE Health Committee of the Birmingham City Council have prepared a scheme for the utilisation of the Salterley Grange Estate on the Cotswold Hills, near Cheltenham, which was purchased by the Corporation for £17,000 as a site for a sanatorium for consumptives. The Local Government Board having sanctioned the expenditure, the committee entrusted Mr. W. H. Ward with the preparation of the plans. Several of the leading sanatoria in the country have been visited by him and the Medical Officer of Health, with the object of obtaining the fullest possible information on their construction and general arrangement. Members of the committee have also visited some of these institutions, and they believe that the scheme which will be submitted to the City Council on January 7th embodies the best knowledge on the subject.

It is proposed to make provision for 40 patients in four blocks of châlets—two blocks being for 16 patients each and two smaller ones for four patients each—and that these buildings shall be erected in local brick, faced with rough-cast stucco. The question as to whether the buildings should be erected on the "single" or "grouped" system, and as to whether the material should be brick or wood, was carefully considered, and the committee early arrived at the decision that "grouped" châlets, as now proposed, will have many advantages over single wooden ones.

The question of the heating of the châlets was carefully discussed, and it was finally decided to provide a small stove in each room, which can be used when necessary. It is anticipated that fires will very rarely be necessary, but to guard against severe cases or exceptional weather conditions, it is felt that some provision should be made.

The question of the necessary furniture for the institution has been carefully considered by the Medical Officer of Health. He estimates that a sum of £1,200 will be sufficient to provide all that is necessary. This amount has been included in the estimates. The committee will ask the Council to apply to the Local Government Board for a loan of £8,500 to defray the cost of the works recommended in their report.

Mr. Chamberlain and the Mary Kingsley Medal.

THE Liverpool School of Tropical Medicine, of which Princess Christian is honorary president, decided to confer the Mary Kingsley memorial medal on Mr. Joseph Chamberlain in recognition of the work he inaugurated by the establishment of schools of tropical medicine. The following letter was sent with the medal to Mr. Chamberlain:—

"January 1st, 1908.

"Sir,—In the name of the Liverpool School of Tropical Medicine, we have the honour to transmit for your acceptance the Mary Kingsley memorial medal.

"In selecting you as a recipient of the medal, the school desires to recognise the fact that your services to the great cause of the advancement of our knowledge of tropical medicine have assisted that cause as effectually as the labours of the most devoted scientists. We trust that you will accept this medal in the spirit in which it is offered, and that it will serve to remind you of a not unimportant work achieved in a strenuous life. On behalf of the Liverpool School of Tropical Medicine, we remain,

"HELENA, Hon. President.
"ALFRED L. JONES, Chairman.
"RUBERT BOYCE, Dean.
"ALAN MILNE, Secretary."

Mr. Chamberlain has replied as follows:—

"Highbury, Moor Green, Birmingham,
January 3rd, 1908.

"Sir,—I beg to acknowledge with thanks the receipt of your letter of January 1st and the Mary Kingsley memorial medal. I highly appreciate the compliment which the Liverpool School of Tropical Medicine has been good enough to pay me. I feel, and have always felt, that the Liverpool School has largely contributed to the altered sanitary conditions of the tropics, and I regard with pleasure any efforts I may have been able to render to the cause, though I feel that they have been small compared with those of such institutions as your own. I recognise your appreciation and value very much your present testimony.

"I am, etc.,
"J. CHAMBERLAIN."

Belladonna Poisoning at Manchester.

AN inquest was held by the Manchester Coroner on January 3rd concerning the death of Albert Clegg, aged 57, a cloth agent, who died on Thursday last from the effects of belladonna poisoning.

The widow stated that on Wednesday evening her husband came home from the Albert Park Bowling Club at Didsbury. He was all right then, and after having a little toast went to bed. The next morning he was all right at half-past seven, but an hour later she heard a noise in his bedroom and found him sick. She gave him brandy, and when she saw him again ten minutes later he was in a semi-conscious condition. A doctor was called in later, but her husband died about ten o'clock. He had been troubled with sciatica, and used liniment for rubbing purposes. He kept the liniment in a bottle on the washstand in his bedroom, and near by was a bottle containing brandy.

In answer to the Coroner, the witness said she knew of no reason why her husband should take his life. He was quite cheerful, and had no trouble of any kind so far as she knew.

Mr. Harvey Simpson, solicitor, said he had known Mr. Clegg intimately for eight years. Last week he complained of sciatica, and with that exception he appeared to be in good health. Witness was with him on Wednesday evening at the Albert Park Bowling Club, and they played billiards together. Mr. Clegg was quite cheerful, and he promised to meet witness the following evening. During Wednesday evening Mr. Clegg had nothing to drink except a teetotal drink.

Dr. Darwin said death was due to belladonna poisoning. The liniment and brandy in the respective bottles would be the same colour. He knew Mr. Clegg personally, and he was perfectly rational.

The Coroner said it was quite possible that Mr. Clegg, having sciatica pains, got out of bed to take a little brandy, and for some reason or other made a mistake between the two bottles.

The jury returned a verdict of death by misadventure.

Illegal Operation at Sheffield.

SERIOUS allegations were made at an adjourned inquest held by the City Coroner, Mr. D. Wightman, on January 3rd, on an unmarried woman, aged 24, who died about a month ago in the Firvale Workhouse Hospital from peritonitis. Two doctors agreed that the use of instruments in performing an illegal operation had set up the disease. The woman made certain admissions as to the performance of an illegal operation, and the inquest was adjourned for the purpose of further inquiries.

The Coroner stated that every available means had been used for the purpose of elucidating the matter, but without success, and he did not think there was any use in further adjourning the inquiry.

Statements were made by Kate Stanton (18), Robertshaw Street, and Martha Procter, Woodside Lane, who had worked with deceased, as to allegations she had made to them in regard to a banksman at Nunnery Colliery, to whom she attributed her disgrace. Mr. Payne appeared for the man, but no evidence was given in any way connecting him with the criminal part of the affair. According to the statements made by deceased to her friends, it appears he denied having had anything to do with her misfortune.

A grave statement was made by Kate Stanton, according to whom the deceased confessed that she went to a herbalist on the Wednesday night that she left her work.

She refused to tell Stanton the man's name, and asked her not to split on him. She said he had told her not to speak about it, as if she did he would get a year's imprisonment.

The Coroner's officer stated that he had seen the man in question, who denied the affair altogether, and said he had no knowledge of anyone having been to him.

The Coroner said he did not think they could carry the matter any further in that Court.

A verdict was returned in accordance with the medical evidence that death resulted from peritonitis, brought on by an illegal operation.

Health of Edinburgh for 1907.

THE number of deaths registered during the past year was 4,978, giving a death-rate of 14.38 per thousand of the population. Of this total 903 were under one year, 529 between one and five, 609 between five and thirty, 1,318 between thirty and sixty, and 1,619 over sixty, of which 34 were above ninety years. Diseases of the chest accounted for 1,061, while 396 were due to phthisis, 221 other forms of tuberculosis, and 135 from cerebro-spinal meningitis. Old age and debility claimed 588 of the total deaths. The zymotic deaths numbered 326, of which 164 were due to whooping cough, 75 to measles, 32 to diphtheria, 24 to scarlet fever, 11 to typhoid, 10 to erysipelas, and 10 to puerperal fever.

The number of births registered during the year was 7,504, giving a birth-rate of 21.68 per thousand. The males numbered 3,856 and the females 3,648, while 583 were illegitimate.

During the year 2,819 cases of infectious disease were intimated in terms of "The Infectious Disease (Notification) Act, 1899," comprising 1,110 scarlet fever, 650 phthisis, 635 diphtheria, 300 erysipelas, 103 typhoid, 19 puerperal, 1 typhus, and 206 suspected cases of cerebro-spinal meningitis.

There were admitted to the City Hospital 3,560 cases, comprising 1,026 scarlet fever, 870 measles, 546 diphtheria, 410 whooping-cough, 152 erysipelas, 130 phthisis, 122 cerebro-spinal meningitis, 91 typhoid, 27 chicken-pox, 12 puerperal, and 1 typhus fever, and 173 were placed under observation. In the course of the year 304 patients enjoyed the amenities of the Convalescent Home at Musselburgh.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of this Society was held on December 20th, Dr. de Havilland-Hall in the chair. The records of the business in the later months of 1907 were stated to have been very satisfactory, as the moderate rate of sickness claims experienced during the autumn had more than balanced the somewhat heavy expenditure of the spring of the year. The number of new entrants was exceptionally large, and as the numbers of deaths and lapses were rather under the average, the net increase of membership is not greater than in any previous year of the Society's working.

The Lees and Raper Memorial Lecture, 1908.

THE Eighth Lees and Raper Memorial Lecture will be delivered in the Town Hall, Oxford, by Mr. William McAdam Eccles, M.S., F.R.C.S., on Tuesday, February 4th, at 8 p.m. The subject chosen is "The Relation of Alcohol to Physical Deterioration and National Efficiency." The chair will be taken by the Regius Professor of Medicine in the University of Oxford—Professor William Osler, F.R.S., M.D., LL.D., D.Sc. The subject is one to which Mr. Eccles has devoted much attention and will be illustrated by the lantern.

Ambulance Tramcars.

AT a meeting of the Metropolitan Asylums Board on Saturday, the Hospital Committee put forward a suggestion that four ambulance tramcars be obtained for use in connection with the small-pox hospitals, at an estimated cost of £850.

Objection to such an expenditure on "elaborate cars, beautifully fitted up," was taken on the ground that second-hand horse-cars suitable for the purpose could be obtained for a few pounds. The answer was that these cars had been tried and found totally unsuitable. It was agreed to purchase two cars only.

Royal College of Physicians of Ireland.

AT the meeting of the President and Fellows of the Royal College of Physicians of Ireland held on Friday, January 3rd, 1908, the membership of the College was conferred on W. J. Maguire, B.A., M.D., R.U.I., Queen's College, Belfast.

NOTICES TO CORRESPONDENTS, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Antipodes.—Nowhere, we believe, is quackery more ripe than in Australia. In a recent report by the Government of Queensland, Dr. Ham, the Commissioner of Health in that Colony, says that: "Australia, like America, is the home of quackery." A large army of impostors, so-called "professors," "herrs," "nurses," "herbalists," and "specialists," with little or any professional training in medicine, are allowed to batten upon a credulous community.

Norfolk.—Such steps will probably be taken, for a recent conference of East Anglian education authorities has issued a report recommending the establishment of a school for blind and deaf children, at an estimated cost of £10,000, to be shared by the various authorities.

RESPIRATORY EMBARRASSMENT.

Doctor: Well, Buckins, how are you feeling this morning?

Buckins: Very much better, thank ye, doctor. The only thing that bothers me is my breathing.

Doctor: Um! yes. We must see if we can't get you something to stop that. —*The Sketch.*

G. W. F. R.—Please find note in reply under "Letters to Editor."

Dr. H. S.—We cannot refer you to any similar occurrence in this country, but M. Marcel Briand has described a case in which a lady and her two daughters, who were in a motor with closed windows for half an hour, became unconscious. They were eventually brought round, but suffered from ringing in the ears, vomiting, and loss of memory. It was found that the machinery of the motor had lately been repaired, and the planks of the floor had not been properly fastened together. The burned gases from the exhaust tube had escaped into the carriage, and the ladies were poisoned by the CO_2 contained in the discharge.

X. P.—We cannot recommend private firms, but must leave you to take your choice among those which are of good repute in the profession.

Meetings of the Societies, Lectures, &c.

Thursday, January 9th.

Royal Society of Medicine (Obstetrical and Gynæcological Section) (20, Hanover Square, W.).—7.45 p.m.: Dr. J. P. Hedley, Dr. Harold Sington (introduced by Dr. Handfield-Jones), and Dr. A. H. N. Lewers: Specimens. Mr. J. Bland-Sutton: On Carcinoma of the Ovary from a Clinical Standpoint. Dr. Carver and Dr. Fairbairn: On Hæmorrhage into the Pons Varolii as a Cause of Eclampsia.

United Services Medical Society (Royal Army Medical College, Millbank, S.W.).—8.30 p.m.: Major M. P. C. Holt, D.S.O.: The Advisability of Operation for Recurrence of Hernia in the Services.

North-East London Clinical Society (Prince of Wales's General Hospital, Tottenham, N.).—4.15 p.m.: Address:—Dr. Robert Hutchinson: Modern Theories of Diet in their Relation to Practice.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. Beresford Kingsford: Some Special Methods of Administering Chloroform and their Relative Advantages.

Mount Vernon Hospital (Central In-Patient Department) (7, Fitzroy Square, W.).—5 p.m.: Opening Lecture:—Sir Thomas C. Allbutt, K.C.B.: Angina Pectoris (Post-Graduate Course).

St John's Hospital for Diseases of the Skin (Leicester Square, W.C.).—6 p.m.: Lecture:—Dr. M. Dockrell: Bullous and Vesicular Eruptions: I., Urticaria; II., Pemphigus; III., Pompholyx; IV., Varicella.

Friday, January 10th.

Royal Society of Medicine (Clinical Section) (20, Hanover Square, W.).—8.30 p.m.: Exhibition of Cases. Dr. Sidney Phillips: A Case of Fatal Illness in a Child with Post-mortem Appearances of the "Status Lymphaticus." The patients will be in attendance at 8 p.m.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. C. A. Parker: Clinique. (Throat.)

Hospital for Diseases of the Throat (Golden Square, W.) —5.30 p.m. First of a systematic course of Lectures on Diseases of the Ear.

Appointments.

Byrne, P. Kevin, M.D., M.R.C.P.Lond., Assistant Physician to the London Temperance Hospital.

Clark, Robert V., M.B.Edin., Medical Officer of Health of Leeds.

Dimock, Horace, M.B., B.C.Cantab., House Surgeon at Addenbrooke's Hospital, Cambridge.

Hailstone, J. E., M.R.C.S., L.R.C.P.Lond., Assistant House Surgeon at Addenbrooke's Hospital, Cambridge.

Higgs, F. W., M.B., B.S.Lond., M.R.C.P.Lond., Medical Registrar to St. George's Hospital.

Legge, J. H., M.B., B.Sc.Lond., Honorary Anæsthetist to the Dental Department of the Leeds Public Dispensary.

Maclure, W. J., M.B., B.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Conisborough District of the county of York.

Quick, Hamilton Ernest, B.Sc., M.B., B.S.Lond., L.R.C.P., M.R.C.S., House Surgeon at the Swansea Hospital.

Ward, J., M.R.C.S., L.S.A., Certifying Surgeon under the Factory and Workshop Act for the Leamington District of the county of Warwick.

Whalley, Frederick, M.B., Ch.B.Leeds, Honorary Anæsthetist to the Dental Department of the Leeds Public Dispensary.

Whitehead, Francis Henry, L.R.C.P.Lond., M.R.C.S., Medical Officer to the Post Office at Battersea, S.W.

Vacancies.

University of Sheffield.—Demonstrator in Anatomy. Salary, £150 per annum. Applications to W. M. Gibbons, Registrar.

Hartlepools Hospital.—House Surgeon. Salary, £100 per annum, with board, washing, and lodging in the institution. Applications to Robert Edger, Secretary, 15, Town Wall, Hartlepool.

Swansea, County Borough of.—Medical Officer of Health. Salary, £500 per annum. Applications to Jno. Thomas, Town Clerk, Guildhall, Swansea.

London Fever Hospital, Liverpool Road, N.—Resident Medical Officer. Salary, £250 per annum, with board and residence. Applications to the Secretary.

Chesterfield and North Derbyshire Hospital.—Senior House Surgeon. Salary, £120 per year, with board, apartments, and laundress. Applications to the Secretary.

Somerset County Council.—The County Education Committee.—Chief Medical Inspector of Schools. Salary, £500 per annum, with out-of-pocket expenses. Applications to the County Education Secretary, Weston-super-Mare.

Great Northern Central Hospital.—Pathologist and Curator. Salary £100 per annum. Applications to L. H. Glenton-Kerr, Secretary.

Fermanagh County Hospital.—House Surgeon. Salary £52 per annum. Applications to C. Wilson, Secretary.

Births.

Addinsell.—On Jan. 3rd, at 6, St. James's Road, Surbiton, the wife of John Howard Addinsell, L.R.C.P. (Lond.), M.R.C.S. (Engd.), of a son.

May.—On Jan. 2nd, at Woodleigh, Ware, Herts, the wife of George Ernest May, M.R.C.S. and L.R.C.P., of a son.

Thompson.—On Jan. 1st, at 4, St. Thomas' Street, London Bridge, the wife of Ralph Thompson, Ch.M., F.R.C.S., of a son.

Thorne-Thorne.—On Jan. 3, at "Grasmere," Mount Vernon Road, Woking, the wife of Berthold Thorne-Thorne, M.D., of a daughter.

Marriages.

Stock—Weston.—On Jan. 1st, at the Church of Emmanuel, Clifton, Bristol, William Stuart Vernon Stock, F.R.C.S.Eng., elder son of Granger Stock, Clifton, to Ella Christine, third daughter of John Weston, The Avenue, Clifton, Bristol.

Moorhead—Quinn.—On Dec. 19th, at Rathmichael Church, Shankill, by the Rev. H. Taylor, assisted by the Rev. J. Dillon, Rector of the Parish, and the Rev. H. Swanzy, Dr. T. Gillman Moorhead, Dublin, to Mary Beatrice, daughter of the late R. Erskine Quinn, Kingstown.

Deaths

Wiltshire.—On Jan. 3rd, at Winkleigh, Tunbridge Wells, Sarah Ann, widow of the late Thomas Wiltshire, L.R.C.P., in the 70th year of her age.

Birch.—On Jan. 1st, at his residence, St. Leonard's-on-Sea, Scholes B. Birch, M.D., L.S. and M.R.C.P.Lond. (retired), aged 82 years.

Granger.—On Jan. 4, at 6, Victoria Terrace, Weymouth, William Slocombe Granger, M.R.C.S., L.S.A., late of Wool, aged 70 years.

MODERN THERAPY.

MEDICAMENTA VERA
P D & Co

Dyspepsia.

Probably most cases of indigestion are due to the inability to convert amylaceous foods into assimilable forms.

Taka-Diastase has been proved to be the most potent—as well as the most convenient—substitute for ptyalin and amylopsin when these are deficient. It is a pure vegetable amylolytic ferment, capable of rendering soluble 150 times its weight of *dry starch* in ten minutes, and much more in a longer period.

Taka-Diastase is far more effective than the best malt extract and other forms of diastase, and is active in acid conditions of the stomach or in the presence of tea, coffee, alcohol, etc. (see articles in *The Lancet*, May 7th, 1898, and *The Boston Medical and Surgical Journal*, April 6th, 1899).

Taka-Diastase retains its activity in all climates. The dose is from 2½ to 10 grains.

BIBLIOGRAPHY.

AMYLACEOUS DYSPEPSIA. "In no case did I find Taka-Diastase fail in giving good results."—*Lancet*, August 7, 1897.

DYSPEPSIA. Excellent results in many obstinate cases.—*Liverpool Med. Chir. Jour.*, Jan. 1897.

GOUTY DYSPEPSIA. Most gratifying results after everything else had failed.—*Lancet*, October 10th, 1903, page 1052. Also see *The Practitioner*, Feb. 1907, page 168.

TUBERCULOSIS. A powerful aid to nutrition and increased strength.—*Medical Magazine*, June 1906.

CHRONIC CONSTIPATION. "Often brings about a cure in the most obstinate cases."—*Therapeutic Gazette*, October 15, 1906.

CONVALESCENCE. Invaluable after typhoid, etc., for enabling the enfeebled digestive powers to assimilate carbohydrate dietary.—*Therapeutic Gazette*, Oct. 15, 1906.

PREPARATIONS.

TAKA-DIASTASE POWDER.

TAKA-DIASTASE TABLETS.
Each contains 2½ grains of Taka-Diastase.

TAKA-DIASTASE, LIQUID.
One fluid drachm contains 2½ grains of Taka-Diastase.

TAKA-DIASTASE with CHOCOLATE TABLETS.
Each contains 1 grain of Taka-Diastase. Specially adapted for the treatment of children.

* * *

The following combinations are specially indicated where peptic digestion is impaired.

TAKA-DIASTASE and PEPSIN COMP. TABLETS.

Taka-Diastase	1 grain.
Pepsin Aseptic (1 : 3000)	1 grain.
Pancreatin Pure	½ grain.

TAKA-DIASTASE, PEPSIN and STRYCHNINE TABLETS

Taka-Diastase	2 grains.
Pepsin Aseptic (1 : 3000)	2 grains.
Strychnine Phosphate	1/100 grain.

(chocolate-coated)

PARKE, DAVIS & CO., 50-4 BEAK ST., REGENT ST., LONDON, W.

180

The published statements of prominent surgeons of all countries show that

ARGYROL

(Silver Vitellin)

is the best silver salt, and that no known agent can compare with it in eradicating gonococcal and other infections, speedily and without discomfort to the patient.

Argyrol is used in 10 per cent. solution as injection in gonorrhœa every 3 hours; in 25 per cent. solution as instillation (diseases of eye) every half hour or hour, and in 25 per cent. solution as local application (throat, vagina, etc.) once daily.

Produced by

BARNES & HILLE,

32 Snow Hill, LONDON, E.C.

One unique effect of

OVOFERRIN

(Iron Vitellin)

is its property of improving the patient's general nutrition in a very striking manner.

Literature on Ovoferrin by recognized authorities in medicine in America and Europe, show that it is a hæmatinic and general tonic of very unusual value.

Ovoferrin is furnished by chemists, on prescription, in twelve-ounce bottles. The dosage is one tablespoonful in wine-glass of water or milk three times daily.

Produced by

BARNES & HILLE,

32 Snow Hill, LONDON, E.C.

MILK of MAGNESIA,

PHILLIPS'

Registered Trade Mark).

(Magnesium Hydrate, Mg: H_2 O_2 24 grains to the oz.)

Is NOT an Emulsion but a PERFECT solution entirely free from Mucilage or any suspensory matter.

PHILLIPS' "MILK OF MAGNESIA" presents to the Profession the ideal form of administering Magnesia wherever indicated.

SAMPLES AND LITERATURE CHEERFULLY SUPPLIED ON APPLICATION.

THE CHARLES H. PHILLIPS CHEMICAL CO., 14 Henrietta Street,
LONDON, W.C.

PHYTIN

IS THE NATURAL SALT OF PHOSPHORUS, PRESENT IN SEEDS AND VEGETABLE TISSUES. NO OTHER DRUG CONTAINS SO LARGE A PERCENTAGE (22.8) of

ASSIMILABLE PHOSPHORUS.

Supplied in form of CAPSULES (each containing the Dose—4.2 grains), or in POWDER, or in LIQUID (for Club & Hospital Practice).

Society of Chemical Industry in Basle (Pharm. Dept.), 8 Harp Lane, London, E.C.

In all disorders of the respiratory tract in which inflammation or cough is a conspicuous factor, incomparably beneficial results can be secured by the administration of

Glyco-Heroin (Smith)

The preparation instantly diminishes cough, augments expulsion of secretions, dispels oppressive sense of suffocation, restores regular, pain-free respiration and subdues inflammation of the air passages.

The marked analgesic, antispasmodic, balsamic, expectorant, mucus-modifying and inflammation-allaying properties of **GLYCO-HEROIN (SMITH)** explain the curative action of the Preparation in the treatment of

Coughs, Bronchitis, Pneumonia, Laryngitis, Pulmonary Phthisis, Asthma, Whooping Cough

and the various disorders of the breathing passages.

GLYCO-HEROIN (SMITH) is admittedly the ideal heroin product. It is superior to preparations containing codeine or morphine, in that it is vastly more potent and does not beget the bye-effects common to those drugs.

Dose. – *The adult dose is one teaspoonful, repeated every two or three hours. For Children of more than three years of age, the dose is from five to ten drops.*

Samples and exhaustive literature bearing upon the preparation
will be sent, post paid, on request

The Patient's Point of View.

The patient's point of view is, of course, always considered by the careful physician. In no class of cases is this consideration more necessary than when treating chronic bronchitis or "winter cough." Many of these patients are elderly and perhaps a little "difficult," so that it is essential to avoid prescribing the continued use of medicine to which they are likely to object. One good reason for prescribing Angier's Emulsion in these cases is that patients are nearly always pleased with it, and frequently comment upon its soothing, comforting effects. Cough is relieved, bronchial irritation allayed, expectoration facilitated. Then, too, Angier's Emulsion has a positive action as a nutritive tonic, whereby it effectually overcomes the constitutional element of malnutrition so frequently associated with these chronic cases. The routine use of Angier's Emulsion for chronic bronchitis and "winter cough" has the endorsement of the most eminent physicians.

ANGIER'S EMULSION

(Petroleum with Hypophosphites).

THE ANGIER CHEMICAL CO., Ltd., 32 Snow Hill, London, E.C.

SCHERING'S

Beta Eucain Lactate

The Local Anæsthetic par excellence.

Possesses all the advantages of Beta-Eucain Hydrochlor. over Cocain, but in addition is readily soluble up to 20 p.c. Can be sterilized by boiling. Toxic effects reduced to a minimum.

SCHERING'S

Urotropin

FABRIK-MARKE TRADE-MARK

Best known and most effective Urinary Antiseptic.

Highly recommended in all Diseases of the Urinary Passage, CYSTITIS, PYELITIS, PYELONEPHRITIS, &c.

A Peptonised Food that can be made in a minute, the addition of boiling water only being necessary.

The 'Allenburys' DIET

A PANCREATISED MILK AND CEREAL FOOD.

By the use of the "Allenburys" DIET all trouble of peptonising milk and farinaceous foods is overcome. In the sick-room it will be found extremely useful, as the food is easily digested and assimilated, is quickly made, and only the exact quantity required need be prepared at a time.

The "Allenburys" DIET is made from pure milk, rich in cream, and whole wheat, both ingredients being largely pre-digested during manufacture. It can be taken by those who cannot digest cow's milk, and provides a light and very nourishing diet for Invalids, Dyspeptics, and the Aged.

For travellers by sea or land this complete food will be found exceedingly valuable.

A Sample with full particulars sent free on request.

NOTES AND COMMENTS.

Soaring Healthwards.

A WELL-KNOWN medical sanitarian recently startled that section of the public to which sensation appeals, by pleading for a more or less universal adoption of skipping as a mode of progression. If we remember rightly, we highly commended the idea ourselves, for it is certain that, were the world to skip through the streets on light fantastic toe, half the worries and trouble of life would disappear, and, owing to collisions, there would certainly be plenty of additional work for doctors. That millennium has not yet been reached, but another gentleman, Dr. McKenzie, of New York, has just put forth an almost more original suggestion, namely, that the jaded should seek to throw off their woes by flying kites for an hour before breakfast each morning. "Flying a kite," he says, "is infinitely more sensible than swallowing time-honoured drugs, and the effect of a merry chat at sunrise in the open air on topics of outdoor interest is sure to be of a beneficial nature. In two weeks, I believe, almost any ordinary case of insomnia or other nervous affection can be cured." Again, we are prepared to endorse the suggestion, but we fear with as little likelihood of producing an impression. An ounce of example is worth a ton of theory, and if these gentlemen, instead of bodying forth their tantalising possibilities, would only turn them to shapes, we might get forward in the path of progress. Why should not some believer start a kite club in Hyde Park before breakfast, or a skipping race to the City? Followers would soon be forthcoming, and the barometer of national physique would rise like the mercury on a dry day. Our imagination kindles at the thought of changing the bed of the sluggard for the exhilaration of the kite on a sloppy January morning, and we only wait for the idealists to show the way before—urging others to follow.

Christian Science again.

AT an inquest held last week at Richmond on a lady who had died of bronchitis, in spite of the ministrations of a Christian Science "healer," the usual sort of tale was told at it. Dr. Michael Taylor, the Coroner, cross-examined the "healer" closely, and elicited the opinion that the lady must have died because she (the healer) had not put enough faith into her prayers for recovery. Followers of her cult, she explained, are graciously allowed to call doctors in when a patient is dying, "because it is the law;" which strikes us as a very convenient method for shelving the responsibility for patients' deaths on to the shoulders of medical men, although the *kudos* of a "cure" is not shared with them. Medical men must be very careful how they are made the dupes of these charlatan practitioners, who will annex their patients without scruple so long as anything is to be made of them, and as rapidly unload them again when there's trouble in the wind. The discredit for the failures should be brought home both to Christian Scientists and to the public by medical men refusing, so far as is consistent with humanity, to be drawn into any case with a Christian Scientist in the background, and certainly by refusing to give death-certificates. By holding an inquest on all patients who have been tampered with by the followers of Mrs. Eddy coroners can bring a strong educative influence to bear on the public, and do something to stop this tomfoolery which is as much blasphemy to the name of Christianity as it is disgraceful to the name of science; for many "healers" are simply impostors of the most noisome type. Honest Christian Scientists, of course, there are, just as there were till recently honest believers in the Druce myth, and honest believers in the godhead of Mr. Piggot of the Agapomone. But preying on these deluded creatures are a number of very offensive charlatans who get a wonderful amount of money by their bluster and pretensions, and these gentry cannot be submitted too frequently to the fierce light of publicity. In the case of adults who choose to be treated by Christian Science, we are inclined to agree with the view Dr. Michael Taylor evidently took in the case under notice, namely, that when they have deliberately placed themselves under a "healer," it is better not to prosecute the friends for neglect; but it should be possible, if inquests are held regularly, for fraudulent imposition to be detected, and followed up by due punishment. The religious question, and the risk of making "martyrs," complicates what would otherwise be a simple matter to deal with.

A Minor Haul.

THE will of Rae, the "miner surgeon," who died a few months ago, was recently sworn at £1,800 odd. As he was a working miner with a family, it is probable that before he embarked on his career as a bonesetter he had no capital, or, at most, a few pounds, and as he was only practising that trade during about three years, his profits, after paying all living and out-of-pocket expenses of every kind, were at the rate of at least £600 a year. To a man who during a longish life probably never had a ten-pound note, such an income must have seemed prodigious, and, with his example before their eyes, it is wonderful that any of his fellows can be found to work at their honourable occupation, when they have only to give the go-by to all ideas of truth and responsibility to achieve similar affluence. Rae was probably not of the exceedingly bad type of quack; he seems to have had hardly sufficient education to know how to go about advertising himself, and his reputation was made more for him by his credulous mates and interested reporters than by him. Still, this almost illiterate creature was able to make a very comfortable thing out of bonesetting, and he was happy in not living long enough to feel the force of the reaction which would pretty surely have followed. Whether the Cardigan brothers, of whom we have still heard but little of late, have now been swamped by such a reaction we do not know, but it is certainly a good plan for flamboyant charlatans to live plainly and make as much money as possible when the boom is on; it does not last long, and the financial ease is some recompence, perhaps, for a conscience that can lie none too easy o' nights.

M. Metchnikoff and Longevity.

It is almost ungrateful to say anything against a man who has rendered such distinguished service to science and medicine as M. Metchnikoff, but, for the sake of his great and well-deserved reputation, we would really be glad if he gave up, or at least contented himself with explaining among his indulgent friends, his theory of accomplishing man's immortality, or indefinite longevity. Although the prolongation of life is doubtless a desirable object, the indefinite prolongation can only lead eventually to a standstill, as death, within a reasonable time, is as important to the business of the planet as life is, and we hardly fancy the course of the earth is to be put out *sine die* because its inhabitants are trying to circumvent its inevitable law. But, from the point of view of those who are jealous about the reputation of science, it is galling to see the name of a man of M. Metchnikoff's service to medicine, made the butt of newspaper jokes and cheap sneers. In one particular M. Metchnikoff is lucky, and that is in possessing a name which does not catch on to the English ear or flow readily from the tongue, so that he is hardly a household word yet, and we should be very thankful ourselves if all the flippant talk and pseudo-scientific patchwork about old age that is being worked up were relegated to more obscurity.

Benevolent Bonesetters.

There is no false modesty about the characters of bonesetters, for by some obscure process, no sooner does one of these benevolent souls think of a kind act, than lo! it crops up in the broad sheets of the Press as though it were the announcement of a fashionable wedding. Without pretending to understand how it is that an anxious world harps on the generous promptings of the bonesetting heart, we can only accept the fact. We recently had occasion to criticise the book prepared by Sir William Treloar's agents to make known the need of his cripple's home, because it was made a medium for advertising certain of these people, and we trust that the advice was not thrown away on the benevolent baronet. Indeed, in view of recent incidents we have reason to think it was not. Mr. H. A. Barker, who now figures as "Dr." H. A. Barker (we do not know what sort of a doctorate is intended), wrote to Sir William Treloar the other day, offering to devote "some of his time" to the treatment of the crippled children of the Metropolis, and Sir William replied with cautious courtesy that he would submit the suggestion to his board of medical advisers, when constituted. Mr. Barker then wrote again, thanking Sir William for his promise, and saying that if his offer was accepted, he would advise part of the home being used as an orthopædic hospital for the treatment, wherever possible, of cases by the "non-cutting method." It is extraordinary how these perspicacious suggestions emanate from intelligent laymen; ideas so startling and original are apt not to occur to the routine medical mind! But Mr. Barker is prepared to back his suggestion, and offers £1,000 towards his scheme, if adopted. Could the loving kindness of the human heart assume a more practical form? We may remark, in passing, that another gentleman of the same fraterinty, Mr. Cliburn, is advertising his own willingness to undertake the treatment of these children. Which will be first, we wonder?

LEADING ARTICLES.

THE INFANT LIFE PROTECTION ACT.

Among the complex phases of the problem of infantile mortality that which deals with "baby-farming" is not the least important. In former times the evils arising from that particular calling became so grave that Parliament at length dealt with the matter in the Infant Life Protection Act; that most beneficial measure has now been in force long enough to justify a fairly accurate estimate to be formed as to its defects. Some of the latter seem so obvious as to need little more than a mere recital to ensure recognition. One of its chief anomalies, for instance, is the exemption from inspection of the child received by any person for a lump sum of over £20, whereas the child taken on a payment under that amount fell under the provisions of the Act. The absurdity of this arrangement has been recently insisted upon by Mr. George R. Sims, the well-known journalist, who has paid much attention to this subject. "The great blot upon this Act," he writes to the *Tribune*, "is the exemption of the 'one child' and the 'over £20' child. How serious this omission is is proved by the fact that within a comparatively short space of time 2,000 cases of cruel neglect have been brought home to the 'one child' receiver, and during the past eighteen months three women engaged in the 'one child' business have been hanged for child-murder." The case for revision of legislation in this direction, indeed, has for a long time been apparent, and it is not surprising, therefore, to hear from Mr. Herbert Samuel, the Parliamentary Under-Secretary of State for the Home Office, that he will shortly introduce, on behalf of the Government, an amending Bill to the present Infant Life Protection Act. It is somewhat surprising that at this precise juncture a deputation representing various powerful bodies should wait upon the Home Office to deprecate the proposed extension of compulsory registration and inspection of homes where two or more children are kept for weekly payment to homes where one child is thus kept. It is of some interest to note the compositon of the deputation, which was as follows:—Lieutenant-Colonel C. W. Long, M.P., the Rev. E. de M. Rudolf, secretary and founder of the Church of England Waifs' and Strays' Society; the Rev. P. S. G. Propert, chairman of the Fulham Board of Guardians; Mrs. Mylnes, vice-chairman of Paddington Guardians; Mr. W. J. Taylor, London Female Preventive and Reformatory Institute; Mrs. R. P. Wethered, Paddington and Marylebone Ladies' Association for the Rescue and Care of Friendless Girls; Mr. A. J. S. Maddison, secretary to the Refuge and Reformatory Union; and Mr. T. W. Hunter, representing the Roman Catholic Society of the Crusade of Rescue. Still more interesting is it to note the nature of the objections. Colonel Long said the deuputation's memorial represented the views of a large number of people. The London County Council had certainly put the present Act more zealously in force than any other body in the country, but if laws which dealt with human nature were made too drastic, although they might remedy some evils, they would increase others. His chief argument ran as follows :—"In the cases of illegitimate children, the desire of the mother to maintain her infant was the best hope of her own reformation, and, therefore, a consideration of the greatest importance from the point of view of national morality. But if, by official inspection, which always meant increased payment of the services inspected, the burden of maintenance was made so great that, in despair, the mother went to the workhouse, or, more probably, deserted her infant, so that it had to be taken to the workhouse; not only would there be an increase in the rates, but there would be the inference that infants could be provided for out of the rates without trouble or penalty to either parent, which must tend to be an incentive to immorality. Five shillings per child was the lowest rate at a baby farmer's, where more than one child was taken in; but official inspection of these homes had already led in some cases to an increase of the lowest rate to six shillings. On the other hand, a young mother could get her infant taken in by a poor friend or neighbour for two shillings up to five shillings a week. These one-child homes were also the best for the children, as well as the cheapest for the parent, as the nurse mothers took care of the children for humane motives, rather than as a matter of business. There was no doubt also that, if the provisions of registration and inspection were extended to those one-child homes, the philanthropic work of the various institutions represented by the deputation would be seriously hampered." The Rev. P. S. Propert said that in his experience, although there was a good deal of neglect in such homes, he had found no evidence of cruelty. A similar attitude was taken by Mrs. Mylnes, who remarked that her experience as a member of the Paddington Poor-law Board was that, while there were a great many cases of cruelty to children by married parents, cases of neglect by foster-mothers in one-child homes were extremely rare. In endeavouring to estimate the value of these two latter opinions the first question that suggests itself is, whether these speakers have had an opportunity of ascertaining the real facts of the case. As to Paddington, we venture to say that a more accurate estimate could be gained of the evils of baby-farming from the testimony of district nurses and visitors, and of out-patient physicians to voluntary hospitals, than from the routine of Poor-law administration. It is impossible not to sympathise with Mrs. Wethered, who said that in the rescue and care of friendless girls these foster-mothers were an immense help. They willingly took charge of the children of girls whom they knew, as an act of friendship; but they would not be so ready with their assistance if they were to be subjected to inspection by a Poor-law official. She feared that an increase of desertion, abortion, and even infanticide was likely to result from any addition to the difficulties and anxieties of fallen mothers. Somewhat more practical was the view of the Rev. E. Rudolf, who stated that the Waifs' and Strays' Society had always a large number of children boarded out in one-child homes—at present the number was 834—and not a single case of cruelty or neglect by a foster-mother had been discovered. In many cases these women took the children in for companionship. He was certain they would refuse to be inspected by a Poor-law officer as if they were mere baby-farmers. From the foregoing views it will be gathered that of the objections some are sentimental, and others spring from the fear that the work of various charitable organisations will be unduly hampered by an extension of the Act. Far more significant, in our opinion, than opposition by the London Diocesan Society, Dr. Barnardo's Homes, and the Charity Organisation Society, is the fact that the London County Council objects to the proposed extension. It is on that account reassuring to learn that the Government has decided to ask the House to appoint a Select Committee to investigate the single controversial question involved in the case of the one-child home. As regards the broader aspects of infantile mortality, Mr. Samuel has announced that the forthcoming Bill deals with many points outside those directly concerned with baby-farming.

CURRENT TOPICS.

Drunkenness and the Probation of Offenders Act.

A welcome instalment of the long-awaited scheme of criminal law reform has reached the British public in the shape of the Probation of Offenders Act. Although that beneficent measure has been in force only a short time, yet some of the decisions already arrived at plainly indicate that in future the magistracy of the kingdom will be armed with potential powers of no mean order as temperance reformers. It need hardly be remarked that under the new Act they have the power to release offenders on probation without proceeding to conviction. In this way a young woman, charged with drunkenness, was released on the undertaking that she would not enter a public-house or a music-hall for the next twelve months. A notice in writing setting forth the conditions to be observed was at the same time handed to the offender. In another case a young man secured release by giving his word to abstain from intoxicating liquors for a period of six months. This new departure in police-court methods should be hailed with acclamation by all advocates of temperance reform. From every point of view the new Act registers a notable advance towards a saner method of dealing with minor lapses, for the punishment of which the rigours of a formal criminal system seem no less harsh than ineffectual.

A Medical Writer "in Penitential Sheet."

The position of the medical author who writes for the public under his professional name and title may not be exactly defined, but it seems clear that if there be any offence it can exist only in the misty realms of an abstract ethical code. When such a man formally declares he does not practice medicine and does not claim to write for his professional brethren, his position appears to be still less amenable to any form of collective control. That appears to be more or less the attitude assumed by Dr. Saleeby, who has written to a medical contemporary stating he no longer acts as a medical man. The journal in question gently castigates him, and alludes to his appearance in penitential sheet. The mildness of this reproof seems to show beyond a doubt that there is no ground for questioning the right of Dr. Saleeby to address the public on medical topics in any capacity he pleases. Nay, more, our contemporary to some extent may be said to have stamped his particular book, "The Conquest of Cancer," with an air of authority and even with a certain modified kind of approval by inserting a bold notice of that volume in its advertisement columns. For our own part we should hesitate in interfering with the freedom of speech enjoyed by any of our countrymen, so long as the public welfare were not clearly assailed. There is another point, however, on which we have felt it a duty to challenge Dr. Saleeby, namely, his claim to the priority of Dr. Beard in the introduction of the trypsin treatment. This we have done as a simple act of fairness and quite independently of the merits of the method itself. The challenge has been formally advanced on evidence furnished by Dr. Shaw-Mackenzie, and we submit that no writer can be regarded as responsible who neglects at once to avail himself of the opportunity of justifying the claims which he has set forth emphatically in the above-mentioned book.

Milk Typhoid.

SOME three or four generations have elapsed since the first definite observations were made with regard to the origin of typhoid fever epidemics in the milk supply of an invaded district. Sanitary science has made many conquests since then, but the problem of milk-borne disease has not yet been brought fully under her control. Of the latter fact we were sharply reminded last week by the report of an outbreak of enteric fever in Glasgow, due to contaminated milk, whereby seventeen persons in the best part of the town were attacked with the malady. Enquiry revealed a not altogether unfamiliar tale. In the farmhouse from whence the incriminated milk was obtained the authorities found a young woman who was ailing, and had been lying in the kitchen the first week of December last. Her illness had been ascribed to influenza and pneumonia, but was in reality enteric fever. This occurrence, read in the light of modern sanitary achievement, points to a lamentable defect in our line of defence against preventable disease. Glasgow enjoys a deservedly high reputation for her administration of public health matters. Yet here we find her citizens attacked by a deadly malady from a source that has been recognised for half a century and more, and one that could be absolutely prevented by a concerted action between town and country sanitary authorities. What is true of Glasgow is true of the whole United Kingdom. How much longer will our practical countrymen be content to wait for some legislative scheme affording rigid control of our national milk supply?

Lead Poisoning from Water-pipes.

YORKSHIRE figures largely in the history of lead-poisoning from drinking water. The explanation is the marked softness of the water and the fact that, collected from the moors, it contains peaty products which are capable of dissolving lead, and, therefore, under certain conditions of storage and distribution, of becoming charged with soluble salts of that metal. Only last week the Ravensthorpe Coroner investigated a case of the kind. A commercial traveller, aged forty, was shown to have been affected with lead-poisoning, and it was stated in evidence that he had been in the habit of drinking a lot of water from the tap. The Coroner remarked that one lesson to be learnt was that people who had lead pipes to their taps should always, before using the water for drinking purposes, open the tap for a considerable time. That is all very well, so far as it goes, but much sounder advice would be to substitute iron for lead piping, and to abolish lead cisterns wherever those relics of a past age still survive. Indeed, it is difficult to understand how any sanitary authority alive to its duties and responsibilities could permit the use of lead pipes for a moorland water supply. For that matter, we are quite of opinion that the legislature would be justified in putting an end to that practice once and for all under such circumstances. Possibly the day may come when lead will be excluded from all contact with drinking water.

Protection of Skin against Rontgen Rays.

THE danger of dermatitis, especially in the case of susceptible persons, is ever a rock ahead in the mind of the radiographer. Any device that can be trusted to circumvent that particular risk without lessening either the therapeutic or the diagnostic use of the Röntgen rays would undoubtedly give a great impetus to the use of this modern method by the medical profession. Accordingly, it is with much interest that we hear it announced that Professor von Jaksch, the well-known Vienna professor, has introduced a simple plan which is said to prevent any possibility of skin burns. His plan is to cover the part of the body exposed to the focus-tube by a screen composed of an exceedingly thin sheet of silver coated with collodion. The metal is practically in the form of foil, as the thickness is stated to be not more than two one-hundredths of a millimetre. Amongst the crowd of ways and means that have been devised for preventing focus-tube dermatitis no single one can be regarded as altogether satisfactory. In the interests of medical work, therefore, it is sincerely to be hoped that our distinguished Vienna colleague will be found to have solved the difficulty.

The Responsibility of Anæsthetic Administration.

THE question recently raised by the City of London Coroner as to whether the responsibility for the proper administration of an anæsthetic rests with the surgeon or the anæsthetist is not likely to be settled off-hand. The lawyers appear to have no settled convictions upon the point, and seem to be quite content to leave its settlement to the advent of the "leading case" so beloved of the judicial mind. Some of our readers may remember that the question was suggested in the course of an inquest upon the body of a patient who died under chloroform at St. Bartholomew's Hospital. In that case the surgeon frankly and freely accepted all responsibility for the administration of the anæsthetic, which was performed by his house-surgeon, a recently-qualified young man. In another similar unfortunate accident the Coroner stated it was the thirty-ninth death under an anæsthetic which he had been called upon to investigate at Guy's Hospital within six and a half years. The aural surgeon who was the operator in that case disclaimed all responsibility for the anæsthetic, on the common-sense ground that he could not look after two things at once in a satisfactory manner. When the Coroner, as a lawyer, informed him that the operator was legally liable, he readily agreed with the suggestion that the sooner the law was altered on that particular point the better. Obviously the public are not likely to be satisfied with the present division of responsibility. Neither are they likely to retain their confidence in the management of Guy's Hospital unless steps are at once taken to place the system of anæsthetic administration adopted in that institution on an absolutely sound footing. We understand that a committee of the medical staff is considering the jury's recommendation on a former occasion: "That in all serious operation cases anæsthetics should be administered either by a staff anæsthetist or by a resident under his immediate supervision," and that a report thereon may be expected shortly. The City of London Coroner may be congratulated for the courageous way in which he has faced a difficult and delicate situation, and it is to be hoped that coroners generally throughout the kingdom will insist on a full enquiry into all deaths under anæsthetics.

The Matronship of Meath Hospital, Dublin.

A rather unnecessary attack was made some short time ago by the Dublin County Council on the Joint Committee of Management of the Meath Hospital. The Meath Joint Hospital Committee had occasion to elect a new matron for the hospital, and after advertisement and due inspection of the different candidates three names were sent up to the Joint Committee with the result that Miss Bradbourne, who had been connected with the hospital for seventeen years, was elected. The representatives of the County Council on the Joint Committee thereupon reported to the County Council that an improper choice had been made, and in proof thereof stated that it had been necessary to vote a sum of fifteen pounds to send the lady to an English hospital to learn her work. The County Council thereupon passed a resolution condemning the action of the Joint Committee. In reply to this resolution the Joint Committee stated " that Miss Bradbourne has proved herself during seventeen years spent in the service of the hospital an excellent nurse, who deserved the confidence of the Joint Committee. The Committee wish it to be understood that in voting the sum of fifteen pounds to be spent in sending Miss Bradburne to inspect some English hospitals, they desired she might be in a position to recommend such improvements as her visit of inspection might suggest." Actions like these on the part of local bodies make medical men and others interested in hospital efficiency dread the control of hospitals by such bodies.

Impurities in Lighting Gas.

In view of the chance of leakage of lighting gas through defective fittings, it is important to all consumers of gas that its noxious properties should be kept at a minimum. Coal gas is, of course, always poisonous, but some coal gas is more poisonous than others. In particular is the gas dangerous in proportion as it contains carbon monoxide. This body is well known to be present in considerable quantities in so-called "water gas," and consequently water gas fittings require greater care than those of gas prepared in the ordinary way. In Dublin the addition of a considerable quantity of water gas to the city gas supply a few years ago was followed by a considerable number of fatalities, due to the escape of gas. It is impossible to say that these accidents would not have occurred if the nature of the gas-supply had not been changed, but the coincidence in time was remarkable. Of late the public in Dublin has had to put up with another impurity. It appears that for some time past there has been a considerable quantity of sulphuretted hydrogen present in the gas as supplied to the public, and we need hardly say that this impurity is highly unpleasant and injurious to health. We understand that the Dublin Corporation has considerable powers over the gas-supply of the city, but we cannot find that they have ever exercised these powers to protect the health of the citizens.

PERSONAL.

The King has appointed to the Consulting Staff of the Officers' Convalescent Home at Osborne, Sir Thomas Clifford Allbutt, F.R.S.; Sir William Bennett, K.C.V.O.; Lieut.-Col. Havelock Charles; Mr. Watson Cheyne, C.B., F.R.S.; Dr. David Ferrier, F.R.S.; Dr. James Goodhart; and Mr. Pearce Gould, M.S.

The governing body of Rugby School have transferred Dr. Clement Dukes to the new post, created for him, of Consulting Physician to the school, with a salary, in consideration of the long series of years that he has acted as Medical Officer.

Dr. William Hunter, M.D., F.R.C.P., has been promoted to be full Physician at Charing Cross Hospital.

The eighth Lees and Raper Memorial Lecture will be delivered in the Town Hall, Oxford, by Mr. William McAdam Eccles, M.S., F.R.C.S., on Tuesday, February 4th, at 8 p.m. The subject chosen is "The Relation of Alcohol to Physical Deterioration and National Efficiency."

Dr. Hernforth Wood has resigned the post of Medical Superintendent of the Liverpool Sanatorium for Consumptives at Kingswood.

Dr. John S. Gayner has been elected to the post of Honorary Administrator of Anæsthetics, and Dr. Hinton Bateman to that of Honorary Officer in charge of the X-ray department at the York County Hospital.

Dr. J. D. Small, Senior Medical Officer of Southern Nigeria, has retired from the service.

Dr. A. D. Brunwin has been appointed Resident Medical Officer of the Colonial Hospital, Medical Officer to the Gaol, and Medical Officer, Suva, Fiji.

In accordance with the provisions of an Order-in-Council, Fleet-Surgeon G. D. Twigg, F.R.C.S.I., has been placed on the Retired List, at his own request, with permission to assume the rank of Deputy-Inspector-General of Hospitals and Fleets.

The Right Hon. the Earl of Plymouth, P.C., C.B., D.L., J.P., Lord-Lieutenant of Glamorganshire, has consented to act as President of the Twenty-fourth Annual Congress and Exhibition of the Royal Sanitary Institute, to be held at Cardiff from July 13th to 22nd, 1908.

A CLINICAL LECTURE
ON
TUBERCULAR LARYNGITIS. (a)

By **ANDREW WYLIE, M.D., C.M.,**

Assistant Surgeon, Central London Throat, Nose and Ear Hospital.

TUBERCULAR disease attacking the larynx, secondarily or associated with tubercle in the lungs or other organs, is a common disease, but as a primary affection it is so rare that at one time its existence was denied. In most cases of pulmonary phthisis the larynx is affected by the tubercle, and in a large proportion it can be diagnosed by the laryngoscope supplemented by clinical examination. It is therefore of great importance for laryngologists to thoroughly examine the chest in any case where there is the least sign of tubercular disease in the larynx, and conversely for physicians to examine the larynx in every case where the least sign of phthisis is detected in the lungs. It is, in fact, a necessary complement to every clinical report, because although the chief source of infection is from the lungs, yet it is held that primary tuberculosis of the larynx does occur without any sign of pulmonary deposit; although this has been clinically proved: pathologically in most cases other organs are found to be coincidently affected. The disease may also extend to the larynx from the tongue, fauces, or even ear, either by direct continuity or by the conveyance of bacilli.

ETIOLOGY.

Predisposing Causes.—It is much more common in males in proportion of about three males to two females, and is generally found between the ages of twenty and thirty years in either sex. Infants and early childhood are almost free from it, but it is by no means rare soon after puberty.

It is most common in those who abuse their voice, but rarely in professional singers. We cannot ignore heredity, especially when attended by habitual mouth breathing, nasal obstruction, &c.

It is the injudicious abuse of the voice, especially in those leading a sedentary, indoor and unhealthy occupation rather than the constant use of the voice, which is one of the most potent causes.

PATHOLOGY.

There are several stages or degrees of this affection. The first is one which we can appropriately describe as *Catarrhal*, since the changes are chiefly those of general transient hyperæmia, gland activity, and superficial desquamative changes. It is, in fact, a stage of irritation. These attacks of acute congestion often alternate with periods of pronounced anæmia. This may pass into a state of *Epithelial Thickening*, which is most marked in the posterior commissure, but also occurs as symmetrical patches on the vocal processes or cords proper. Another phase consists of *actual localised or diffuse infiltration of the subepithelial connective tissue* in the neighbourhood of the glands by lymphocytes, true circumscribed tubercles being the result. These may either subside, caseate, or ulcerate. The ulceration may involve the surface or extend deeply into the cartillages, producing perichondritis and necrosis, although some authorities hold that fully-developed tubercles do not undergo fibrosis. Coincidentally, wherever there is much loose connective tissue œdema is well marked. This is a most striking feature of laryngeal tuberculosis, especially when it involves the epiglottic and ary-epiglottic folds. The actual seat of definite tubercle is most commonly the ventricular bands, the walls of the ventricles and saccules, since these structures normally contain lymphoid tissue (like tonsils)—a favourite site for tubercular deposit. Although tubercular bacilli cause the process, yet they are not pus-producing organisms, and many of the changes and phenomena which take place are really due to the co-operation of other bacteria, such as diplococci, micro-tetrageni, &c., so often responsible for acute catarrh, and, later, other pyogenic bacteria such as streptococci, staphylococci, &c.

The probable cause of infection is by penetration of the surface epithelium by the tubercle bacilli which find their way into the lymph radicles, and eventually reach the deep lymphoid channels where, by endothelial activity, the tubercular foci are soon formed.

The tubercular process may assume another form—viz., the hyperplastic, marked by the development of granulomatous masses, which may present the appearance of new growths. They vary from a mere thickening, or sort of "cocks' comb" projection in the posterior commissure, to large smooth or ragged structures in any region of the larynx. They are true tuberculomata and consist of fused tuberculous elements with an abundance of lymphocytic infiltration, often covered with stratified epithelium or forming a rough ulcerated surface.

SYMPTOMS.

1. *Dysphonia.*—This may vary in degree from a slight huskiness and loss of quality to complete disappearance or aphonia. It is a most important symptom, and may be the only one present for a long time. Gradual but certain increasing feebleness and change in character, with occasional intervals of improvement, is a most significant feature.

2. *Cough.*—In the early stages it is usually irritable and dry. Irritable, since the larynx and pharnyx are exceptionally hyperæsthetic and dry, since there is no pus-producing area. It is only in acute catarrhal attacks there is much secretion. Later on, however, the local tenderness increases and cough paroxsyms are most pronounced, with abundant and "streaky" expectoration.

3. *Expectoration.*—In the early course of the disease it is scanty, mucous and "streaky," with few bacteria, tubercle bacilli being absent or very scarce. Later on, with the onset of ulceration, tubercle bacilli are plentiful, together with lymphocytes and leucocytes. It is now not only profuse, but is sometimes coloured. If the lungs are only slightly affected a great deal of this sputum is due to excessive salivation, which, owing to pain and discomfort in swallowing, accumulates in large quantities.

4. *Dyspnœa* is present in all stages and in varying degrees. It must be functional, due to general or cardiac weakness, or it may be obstructive, due to purely local causes generally, in the latter periods of ulceration and œdema.

5. *Deglutition.*—Disturbance of this function is one of the most prominent symptoms of laryngeal

---

(a) Delivered at the Central London Throat and Ear Hospital on September 20th, 1907.

tuberculosis. It may vary from a slight discomfort in swallowing to one of intense pain (odynphagia), when deglutition is almost impossible. Difficulty of swallowing (dysphagia) is chiefly due to structural changes in the laryngo-pharnyx. Odynphagia is chiefly caused by perichondritis (arytenoid and epiglottis), which gives rise to excruciating pain during the contraction of the lower constrictors of the pharynx and the sphincters of the larynx. This also gives rise to considerable accumulation of mucus, and even food, which add to the patient's troubles, and starvation follows if means are not taken at once to alleviate this serious and important complication.

These are the chief special symptoms to which we may add the more general symptoms as :—Evening rise of temperature, sweating, emaciation, asthenia.

Clinical Signs.

Before dealing in detail with the special clinical features characteristic of laryngeal tuberculosis, it will be expedient to say a few words on the so-called *Pre-Tubercular Stage*, to which so much importance has been attached. This stage is practically an exaggerated catarrhal phase marked by recurrent attacks of mild laryngeal catarrh, dysphonia and local anæmia. Briefly the pronounced features are :—(1) Intense pallor of the laryngeal mucosa with intervals of "patchy" hyperæmia, not evenly diffused as in ordinary laryngitis. (2) A greyish macerated appearance of the posterior commissure and inter-arytenoid fold. (3) Patchy thickening of the cords themselves, especially in the region of the vocal processes. (4) Occasional impaired adductor movements of the cords.

It is extremely difficult to arbitrarily arrange the order in which different regions of the larynx are attacked, as so much depends upon the intensity of the process. One is tempted to classify tubercular disease into acute and chronic forms, but this classification would also be undesirable. It will, therefore, be more practical to consider the most striking features seen by the laryngoscope in different degrees and stages of the disease as seen in this country.

Every case presents one or more of the following changes :—(1) Colour ; (2) texture ; (3) form or contour ; (4) movement.

With regard to colour in the pre-ulceration period, the larynx is markedly pallid, except after a severe paroxsym of coughing or during an acute-catarrhal attack. The pallor now involves those regions which are normally tinted, such as ventricular bands, inter-arytenoid folds, &c., independently of general anæmia. Any deviation in colour, texture, form, and movement of the cords will be recognised at once by any one familiar with the structure of the normal larynx. In all cases, ulceration œdema, textural asymmetry, and restriction in the movements of the cords, should be carefully looked for. Limited mobility of the cords may be due to many causes. It may be arthritic, caused by implication of the crico-arytenoid joint or infiltration of the structures generally.

Differential Diagnosis.—In the early stages it is most important, and also very difficult, to differentiate early tubercular laryngitis from hysterical or functional aphonia. Hysterical aphonia is rarely a simple hoarseness or dysphonia, but it is a complete inability to phonate, which comes on suddenly without any change in the quality of the voice or cough and associated with other hysterical phenomena. In *Tuberculosis* complete aphonia is rare ; it is either a dysphonia, preceded or attended by hoarseness and getting gradually worse. It is in these cases where this symptom is only present for a short time and when there is no positive laryngoscopic evidence that much hesitation in diagnosis need be felt. In both cases anæmia is marked, both local and general, although in tuberculosis it may be only local. In tubercle there is generally also marked hypersensibility of the larynx, pharnyx, and fauces, while it is exactly the reverse in hysteria.

In both cases a marked catarrhal condition may be present which at once marks the diagnosis ; in a simple transient laryngitis the mere application of cocaine may relieve the congestion, but when infiltration of the tissues has been at work the application of cocaine does not change the colour and texture to any great degree. Cough may be present or absent in either, but it is more rare in hysteria, in which a "choking sensation" is common. In the event of tubercle, infiltration of the cords is generally unilateral and partial at first ; often only the posterior third is involved. Upon ulceration developing it will be seen to have a decided superficial and "nibbled" character, with a "beaded" base. The ulcers may be multiple and extend by fusion.

Sometimes long before ulceration happens the posterior commissure becomes corrugated and thickened, preventing proper adduction. This is a variety of *Pachydermia*. The inter-arytenoid fold becomes also thickened, presenting a convexity upwards which may soon break down and exhibit an irregular granulation surface. At this time perichondritis of the arytenoids is shown by a characteristic pear-shaped translucent swelling of the mucous membrane covering them. This is a feature rarely seen in any disease but tubercle. As soon as ulceration becomes marked a carefully-taken "smear" will at once reveal the bacilli. This is a much more certain method than examining the sputum, which is frequently unobtainable. In earlier stages bacilli are more difficult to find.

The appended table will help to differentiate it from syphilis and malignant disease at this stage of its progress.

Tubercular Laryngitis.	Syphilitic Laryngitis.	Malignant Disease.
Pallor of larynx		
Catarrh of one cord usually posterior third	One or both cords and generally anterior ends	Always one cord
Ulcers are small, grow slowly, edges ill-defined, base nodular, spread superficially, and when healed no deep scarring left	Ulcers large, grow quickly, edges punched out and undermined and tend to grow deeply and leave deep scars	Slight want of movement, a sort of dragging due to the growth
Irritability on laryngeal examination	Tolerance on laryngeal examination	
Intense odynphagia	Dysphagia often slight	Odynphagia and dysphagia variable and late
Granulations are diffuse, irregular, œdematous, and greyish white	Gummata are usually unilateral, and dull red colour	Cauliflower looking growth, one cord
Epiglottis attacked late in the disease on the laryngeal side	Epiglottis attacked soon, and in its anterior aspect	
Physical signs in chest	Scars on fauces	
Tubercular bacilli in sputum or swabs from larynx		
Evening rise of temperature	History of rash, &c	Age of patient
Night sweats	Peculiar harsh voice	
Character of voice		

Prognosis of Tubercular Laryngitis is grave in every case, but under careful hygienic surroundings the ulcers may heal, but they are unfortunately often only quiescent for a time, and re-awaken into activity on the slightest provocation.

The prognosis depends : (1) On the amount of dysphagia and odynphagia present ; (2) on the extent of the lung and general infection ; (3) upon the stage of the disease.

Treatment.

Absolute rest to the larynx is a most essential part of the treatment. Hilton's principle of rest to all diseased parts must be applied here most particularly. Patients should be kept like prisoners, and allowed only paper and pencil to communicate their desires, and on no account allowed to whisper. Irritable condiments, highly seasoned foods, smoking, &c., should be prohibited. Any cough, however slight, should be soothed as quickly as possible.

The Fresh Air Treatment is essential, unless the larynx is in an acute or far advanced state of the disease.

Nourishing, Wholesome Diet, as milk, eggs, soups, &c.; no rich foods, oils, or drugs should be given if they tend to injure the digestion or hurt the appetite.

Opsonic Treatment.—This should never be undertaken unless the patient can be kept at perfect rest, mentally as well as bodily, and in co-operation only with the strictest sanatorial attention. It is useless to make any opsonic observations while the patient is taking active exercise, otherwise the results will prove not only misleading, but probably harmful. Should the necessary favourable conditions be available, there can be no doubt that the tuberculin vaccination, although in its infancy, affords a valuable method of treatment.

Dysphagia is a grave symptom, and must be relieved as soon as possible. Patients swallow semi-solids more easily than fluids or solids, especially when lying in the prone or semi-prone position, with their head over the couch and taking the food through a tube held below the mouth. Raw unbroken eggs are easily taken in this position.

Local Treatment for Dysphagia.—(1) Orthoform and resorcin in powder, equal parts; by auto-insufflation through Leduc's tube, causes great relief. (2) Anæsthetics, as cocaine or menthol and paroline, injected into the larynx are useful. (3) Excision of a piece of the swollen arytenoid or epiglottic region by punch forceps eases for a considerable time this painful symptom.

Cough, when only slight, is relieved by demulcents, such as Iceland moss jujubes or jelly, but when the patient's rest and sleep is disturbed by it, Heroin, which does not affect the appetite, will be found superior to Morphine. Local remedies for tubercular laryngitis are useful when the pulmonary condition is not far advanced and when the strength of the patient is good.

Laryngeal applications injected into the larynx by means of a laryngeal syringe, guided with the larnygeal mirror, are most beneficial. They should be injected daily in order to have a permanent effect, especially when pulmonary complications are active and the sputum is highly charged with mixed bacteria. The following solution: Creasote or guaiacol, 5 per cent.; menthol, 1 per cent.; oil amygdal dul., 94 per cent.; relieves the cough and pain in a marked degree.

Local Reagents or lactic acid, in strengths from 10 per cent. to 60 per cent., also carbolic acid, formalin, and others applied by means of a swab, are efficacious.

Surgical Methods are resorted to when the dysphagia is very severe and when tubercular granulations are too profuse. These can be removed from the inter-arytenoid space, base of the epiglottis or cords by means of Heryngs' curettes (a few drops of a 5 per cent. solution of cocaine is first applied).

The galvano-cautery has been used with considerable success in reducing tubercular nodules or tuberculomata.

It is absolutely essential for tubercular patients to have a free nasal and naso-pharyngeal passage, so as to allow deep and normal breathing. Tuberculosis is liable to infect any adenoid vestige or unhealthy mucous membrane, therefore any such must be promptly and thoroughly dealt with.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Paul Claisse, M.D., Physician to the Pitie Hospital, Paris. Subject: "Embolism consequent upon Lesions of the Left Heart."*

ORIGINAL PAPERS.

SOME IMPORTANT ASPECTS OF SUPPURATION OF THE MIDDLE EAR. (a)

By J. DUNDAS GRANT, M.A., M.D.Ed. F.R.C.S. Eng.

Surgeon to the Central London Throat and Ear Hospital, and the Brompton Hospital for Diseases of the Chest, &c.

THE lecturer referred to the extreme seriousness of the various complications of suppuration in the middle ear, suggesting that the aurist probably saw more than his fair share and the general practitioner of medicine less, but whoever had experience of them realised the extreme danger and anxiety connected with them. He narrated a large number of cases from his experience of which the results had been fatal; he pointed out as far as possible the reasons for their having gone wrong, and how such results might, if possible, be prevented in the future. In some of the acute cases, however, incision of the tympanic membrane had been postponed or the opening of the mastoid cells had been relegated until infection of the blood or of the cranial contents had taken place. He discussed the reasons which had led to the delay, but in view of his later experience considered that these reasons were in many instances quite insufficient.

By way of contrast he referred to some illustrative cases in which early intervention appeared to have been the means of averting dangerous complications. He expressed the opinion that with antiseptic precautions even those who did not profess to be operative experts might put their patients in safety by making an opening in the mastoid cells when more skilled aid was not available. He advocated early and quick operation in diabetics in view of the rapidity with which the mastoid bony tissue breaks down in these subjects, though no doubt a positive result of the aceto-acetic test would be a contra-indication.

Among interesting errors in diagnosis he quoted a case of lateral sinus phlebitis, which had been previously diagnosed as enteric fever and one of enteric fever which he himself had diagnosed as otitic septicæmia. In another case he had found lobar pneumonia to be the cause of constitutional disturbances which had by others been attributed to purulent otitis. In another exceptional case certain cerebral disturbances were in view of a history of former otorrhœa attributed by the physician in charge to a probable intracranial complication of middle-ear disease, but in reality the lecturer had attended the patient for condylomata of the meatus, and the cerebral disturbances disappeared rapidly under treatment by means of mercury and iodide of potassium.

The difficulties in the diagnosis of malignant disease and tuberculosis when affecting the external and middle ear were described and illustrated by cases occurring in the lecturers' experience.

He considered the recognition of cholesteatoma

(a) Abstract of Second Hunterian Lecture, delivered before the Hunterian Society, January 9th, 1908.

of the middle ear as of vital importance in chronic suppuration of the middle ear and pointed out the dangers attending the use of watery solutions for instillation or syringing when this condition was present. Alcoholic solutions were, on the other hand, of the greatest value.

Dr. Grant referred to the indebtedness of students of otology over the whole world to Dr. Newton Pitt, the honored Fellow of the Hunterian Society, for the invaluable statistical and pathological study of the fatal sequelæ of suppurative middle-ear disease forming his Goulstonian Lecture.

CONTRIBUTION TO THE STERILISATION OF AIR.

By Dr. S. BERNHEIM,

Paris.

[Specially Reported for this Journal.]

The importance of the composition of air for animal life need not be proved since Pasteur's, Strauss', Laveran's, and Miguel's researches on the microbes contained in the atmosphere. In one day 10,000 litres of air pass through an ordinary man's lungs, that is to say, more than 400 litres per hour.

Modifications in the composition of atmospheric air are the cause of great disturbances in organism, and sometimes lead to death. These modifications differ, whether one examines air in the country or in large towns. While country air hardly contains from 200 to 300 germs per cubic metre of air, the city atmosphere, especially that of thickly populated centres, may contain as many as 45,000. My opinion is, that all these figurative elements, these living corpuscles, constitute the principal pathogenical agent of transmissible microbian diseases.

The first prophylactic consideration might have urged us before now to seek for means of sterilising the air we breathe. But, other imperious reasons exist both in medicine and surgery. In hospital wards, in attending surgery or accouchement cases, the air, saturated with micro-organisms, is a constant danger for the patients, for those who have undergone an operation or given birth to a child. Very often the most competent practitioners have observed, in spite of rigorous precautions, cases of infection of exterior origin. After a perfect asepsy, one may reasonably suppose that the contagion is due to an aerial origin.

However this may be, we thought it would be interesting to attempt to sterilise air charged to the utmost with bacteria, even if fully contaminated with a fine flora of microbes. To attain our end we used the simplest aparatus possible. It consists of :

1. A rectangular box containing a vat made of metal having good conducting properties, which is submitted to the action of a source of heat (gas or coal chimney). The said vat contains filtering matter (amianthus or filings).

2. A saturator is placed at the top of the vat, only containing plain or medicinal water, this saturator prevents the unpleasant dryness of the atmosphere. The inner sides of the box and vat are bored at their lower part by an opening on each side (exhausters), and at the top, at the level of the saturator, by two other openings by which the air escapes after having passed through the filter at a temperature of 180°. This high temperature is controlled bv a thermometer placed immediately above the filter of filings. In order to avoid the scum which inevitably arises from the dust, a movable basket is placed underneath the filter, into which all the sterilised dust falls. The dimensions of the apparatus vary according to the importance of the room. If the room is small, an alcohol lamp is sufficient to start the apparatus working and to bring it up to the temperature which the sterilisation of air requires. When a larger room is to be sterilised, and when one wants to arrive at a more complete sterilisation, the apparatus requires a more active and lasting fire. The exhausting action of the apparatus is very powerful, for the maximum of dust and germs may be ascertained half an hour after the operation begins.

For the last two years we have been trying a large number of experiments, and we are now only relating those which have been carried out with all the care that such researches deserve. Very often, indeed, unskilful assistants, after having entered the room fixed on during an experiment, have introduced a new atmosphere more or less charged with microbes. In order that the demonstration may be of value we must previously test the air of the room which is being experimented on at different points and heights, without giving any means of escape. By reason of natural orifices, a house is never and absolutely permeable, and that is the reason why it is very difficult, and nearly impossible to completely sterilise the air in a room. However, we have twice obtained this ideal result. Moreover, here is the report of the experiments just as they worked out :—

We gathered the dust in the air and scattered it according to Miguel's process. In most of the experiments an assistant stayed in the room in order to fan the air and cast the dust into a vacuum. It is true that that experimental measure is really useless, because in the natural circulus of the air dusts are generally gathered and kept up in the atmosphere, the movement being helped by heat.

In one experiment we started with 10,000 bacteria to a cubic metre, and two hours and a half after we began the experiment the air only contained 1,660 bacteria.

In another experiment, where the air was polluted, we started with 95,000 germs, and after an hour we found only 15,000 germs.

In another experiment we started with 47,500 germs, and after one hour and a quarter they were reduced to 2,500.

Here is another experiment, the air of which had been polluted. When we began the air contained 275,000 germs, and after one hour only 32,000.

In another experiment, in which the air contained at the beginning 82,500 germs, after two hours we found only 22,500.

Here is another experiment : We started with 45,000 germs, and finished with zero. No settlement was developed on the gelatine. But, as a matter of fact, this result can only be obtained and hoped for in very exceptional cases. In addition to this, we could relate a great many other experiments which resemble the preceding ones, that is to say, we have always obtained a considerable decrease of bacteria and mouldiness.

Considerations.—It is indeed very easy to renew and check our experiments. For our apparatus is so plain that anybody is able to construct one exactly similar and attach it to any chimney which draws well. An examination will show a heavy deposit of dust on the gridiron and on the filter of filings. As this matter rises to a high temperature the germs that travel over it die without fail. And, indeed, in all those experiments we obtained an exact result. After two hours of combustion we have considerably reduced the number of bacteria, to sixteen or seventeen times less numerous after the experiment is terminated. With a fire which lasts longer we shall be able to reduce the number of germs to a strict minimum, and possibly nearly to zero.

The importance of these results will be understood by all hygienists, surgeons, and accoucheurs. We know that air is not at all, or very little, harmful in regard to its chemical alteration, but only according to the germs it contains. If we can hope to sterilise with a simple apparatus the air of a dwelling-house, accidentally or continually overcrowded, this is an important hygienic progress for preserving health. We sterilise milk, we pay attention to a quantity of alimental commodities, especially meat, we boil water to avoid typhoid fever; why shouldn't we purify the air of apartments and habitations?

The "ærosterilisator" is especially designed for hospital wards, schools. colleges, barracks, where the air is so harmful. It will be of great use for all windpipe diseases, where pure air, the important food of the lungs plays so important a part. Give good food to a consumptive patient, with absolute rest in a vitiated atmosphere, and disease will continue its grave course; put this same consumptive person in an atmosphere free from bacteria, with the same rest and nourishment, and you will bring him to a state of health and to a cure. It is the same thing for those suffering from pneumonia, bronchitis, and emphysema.

Here is, therefore, a first list of directions for the "ærosterilisator." But what is one to say of the operating of accouchement rooms, where the chief operators take such precautions to avoid all infection from outside?

We are convinced that all these operators would be glad to strengthen their chances of success by sterilising beforehand, and during the operation, the air in their rooms. This new aseptic *guarantee* is so important that we need not further insist on it.

THE DIAGNOSIS AND TREATMENT OF

SIMPLER FORMS OF CONJUNCTIVITIS. (a)

BY LESLIE PATON, M.B., F.R.C.S.

GENTLEMEN,—Some explanation would seem to be demanded for choosing this somewhat hackneyed subject for a paper to your Society. It is not that I have anything new to say on either diagnosis or treatment. Very few of the great number of writers on this subject do seem to have anything new to say about it. Two factors influenced me in the choice: the first, a realisation that the commonplaces of a specialty were not of necessity commonplaces to men working on other lines; the second being that just at the time your Secretary asked me for a paper, a series of cases had come under my notice in which the non-recognition of any differentiation between the simpler forms of conjunctivitis had led to mistakes in the methods of treatment, or, on the other hand, a method of treatment had been adopted which had resulted in the perpetuation of the condition which it had been intended to relieve.

In using the term, "the simpler forms of conjunctivitis," I am excluding trachoma and follicular conjunctivitis, and also, except in an incidental fashion, phlyctenular conjunctivitis. Clinically, then, my subject includes catarrhal, purulent, and membranous or pseudo-membranous conjunctivitis. If I were driven to giving a simpler classification, I would say that I wish to talk about—(*a*) the inflammations for which the general practitioner prescribes boric acid lotion, and (*b*) those which he paints with silver nitrate. And, personally, I have found that to include the greater bulk of cases of conjunctival inflammation. Boric acid lotion is an excellent remedy. Unfortunately, it is of very little service in the type of case which forms the majority of all cases of simple conjunctivitis. Against the habit of prescribing it with an admixture of cocaine to relieve the pain and congestion I must most vehemently protest. I have seen many prescriptions for such lotions, but I am more and more convinced that the regular prescription of cocaine in any lotion or ointment for home use is a most vicious practice, and has in many cases had the result of perpetuating, or at least prolonging, the course of the malady to which it seems to give temporary relief. As to silver nitrate, in many cases it is the most valuable substance we can use, but in some cases it is of positive dis-service, whilst in others its use has to be guarded by precautions which are not always observed.

I have inferred that there is some basis for a more accurate differentiation of types of conjunctivitis than that given by the terms catarrhal, purulent, and pseudo-membranous. Of course, the best diagnosis will always depend on the identification of the exciting cause—in the majority of cases a bacterium. It is too much to expect a busy doctor to be in a position to prepare even smear preparations, far less to make cultures from every case of conjunctivitis, and it is the function of the specialist, as far as possible, to correlate the clinical aspects of any type of disease with its exciting cause, so as to enable any careful clinician to diagnose with some degree of probability whether the case before him is one caused by the diplobacillus of Morax, by the Koch-Weeks bacillus, by the pneumococcus, or by any of the other bacilli and cocci which may be the exciting cause of conjunctivitis. The organisms to which some pathogenic effect has been or is ascribed in connection with the conjunctiva, may be divided roughly into three classes:—(*a*) Those which are directly pathogenic, bringing about an inflammation without any other contingent cause when introduced into an otherwise healthy conjunctiva. In this class would be included the bacillus of Koch-Weeks, the diplobacillus of Morax, and the gonococcus, bacteria against which no normal immunity exists. (*b*) Bacteria which may be present, and frequently are present, in a normal, healthy conjunctival sac, but which under certain conditions may set up inflammation. Pneumococcus and certain streptococci are in this class—bacteria against which there is a normal immunity sufficient to protect, unless when for some reason there is a diminished tissue resistance or an increased germ virulence. (*c*) Organisms which only attack a tissue already weakened by some other infection. Such organisms are the staphylococci and most of the streptococci. In which class we should include Lœffler's diphtheria bacillus must depend on the answer we can give as to its relationship to the xerosis bacillus. The latter, and staphylococcus pyogenes albus, are practically normal inhabitants of the human conjunctival sac. If, then, we regard the xerosis bacillus as only an avirulent type of Lœffler's bacillus, the latter must be put in class (*b*); otherwise it would normally go into class (*a*). Until bacteriologists decide this question, the hapless bacillus of diphtheria remains suspended like Mahomed's coffin.

We find, then, three classes of organisms: (*a*) those which always cause conjunctivitis; (*b*) those which sometimes cause conjuctivitis; (*c*) those which attack a conjunctiva only when weakened by the attacks of *a* and *b*.

Classes *a* and *b* will include the majority of cases of simple conjunctivitis. Arenfeld, in his book on the "Bacteriology of the Eye," gives statistics of the eye clinique at Freiburg. Of 12,000 patients, 900 had some form of acute or chronic conjunctivitis; 519 of these were caused by the diplobacillus of Morax; 41 by the Koch-Weeks bacillus; 34 by the pneumococcus; 12 by gonococcus; 6 by diphtheria; 5 by streptococcus; 2 by the bacillus of Friedländer; 3 by the influenza bacillus. Of the remaining 278 cases, many showed the usual conjunctival inhabitants, staph. alb. and xerosis, the micrococcus catarrhalis was found 9 times, but the nature of the actual causative germ remained obscure. I think that table gives a just view of the relative frequency of the various agents. And you will note the great preponderance of the diplobacillus of Morax. Some years ago I made a series of observations on cases attending St. Mary's Hospital during a period of six months with acute and chronic conjunctivitis, with the result that I found about 50 per cent. of the cases were caused by this diplobacillus. Gonin's statistics give 185 cases out of 365 caused by it, and generally it is safe to say that diplobacillary conjunctivitis is the most frequent form of simple inflammation. Now it is the one form for

---

(*a*) Read before the Harveian Society of London, Dec. 12th, 1907.

which boric acid is of little use, and silver nitrate is positively harmful. Luckily, the clinical picture it presents is a fairly straightforward and consistent one. It mostly occurs in adult life, and when it attacks children it is very apt to cause severe marginal blepharitis. In adults the features are so characteristic that one can usually pick out in an out-patient clinique such as Moorfields a series of a dozen cases, and predict with certainty that the diplobacillus will be found in each one. The patient comes with the complaint that the lids are gummed together in the morning, or very heavy, and that they have to be bathed with warm water to get them to open at all. This process is sometimes painful, but shortly the pain passes off, and during the day the eyes feel fairly comfortable. Towards evening the eyes begin to prick, especially in the corners. This may commence so sharply that a man will assert that he has got a bit of grit into his eye, and will tell you exactly where he was when the grit went in. The whole upper lid feels as if a dustbin had been emptied into it, and the ball of the eye feels hot and fiery. The discomfort during the evening may be very considerable, even giving rise to headache, and nearly always accompanied by a desire to scratch the inner angles of the eye violently. Usually a period of three or four days elapses between the infection of the two eyes, the incubation period of the organism being from three to five days. Objectively the most obvious sign is the reddening and inflammation of the angles of the eye and the lid margins. The caruncle is usually bright red. Along the roots of the lashes there is a fine greyish deposit, and at the inner angle a little mass of greyish yellow fibrinous matter, in which usually great numbers of the organism can be found. The palpebral conjunctiva is usually slightly inflamed and somewhat roughened, but the ocular conjunctiva, apart from the angles, is seldom much affected. The most characteristic feature, apart from the angular redness, is the erythematous condition of the skin of the lids. Usually the skin at both angles has a slightly eroded appearance, and the rest of the skin along the margins has a dry, crackly, semi-glazed appearance as if it had been badly starched. The disease usually commences in a sub-acute fashion, becomes chronic, and persists if untreated for many months. As the symptoms are often mild, it may be many months before treatment is sought. This form, then, is clinically chronic, angular conjunctivitis; etiologically it is diplobacillary conjunctivitis. Smears prepared from the small fibrinous deposit at the inner angle usually show the organism in great numbers. It is a squat, dumpy, squarish bacillus, always occurring in pairs, which sometimes form chains of several pairs. It does not grow well on ordinary media, but on blood or inspissated serum, or serum agar, it can be cultivated. If the medium does not suit it, it very soon develops involution forms of the most varied description.

If I have been successful in my clinical description, I think you will recognise that this individual with the bleary, red-rimmed eyes is of fairly frequent occurrence. Now the treatment to be adopted is not boric acid and silver nitrate, but zinc sulphate and again zinc sulphate. A lotion containing one or two grains to the ounce, made up with a little cherry laurel water, will do more good in three or four days than boric acid will do in a month. This smarts—in some cases it smarts very badly—and you have to warn people of it. I usually tell them to retire to a private place, where they can express their feelings strongly before using the lotion; but, whatever you do, don't prescribe a little cocaine with it just to take away the pain. If you do, the relief is immediate, but in a short time the congestion recurs, and, like dram-drinking, the effect is shorter with each dose, and in a week or ten days you get a sodden condition of congestion much more difficult to treat than the original inflammation. Again, silver nitrate is of no service, because the organisms are surface livers, and you do not want to produce exfoliation of diseased conjunctiva to carry away deep-seated organisms. Argyrol is in some cases of service, but the mainstay is zinc sulphate. For the comfort of the patient it is advisable to prescribe a simple ointment, to be used at night, to prevent the gumming of the lids. Vaseline is often sufficient, or a 1 per cent. iodoform ointment, or where the pricking is very marked I frequently order zinc oxide made up with lanoline, olive oil, and liquor calcis to a creamy consistency.

The ordinary cases of acute purulent or muco-purulent conjunctivitis may be caused by the Koch-Weeks bacillus, the pneumococcus, or the gonococcus. If we except cases of ophthalmia neonatorum from our purview, the majority of which, though by no means all, are caused by gonococcus, we find that only a very few are due to this last organism—12 out of 900 in Arenfeld's list. This is fortunate, because undoubtedly the most virulent forms of conjunctivitis are caused by the gonococcus. Within 24 hours the conjunctival œdema may be so intense that the lids cannot be separated, and the swollen conjunctiva projecting through the lids may seem in danger of sloughing from strangulation. And when ultimately, by slitting the canthus and free incision, one does obtain a view of the cornea, one often finds it already opaque and ready to slough.

It is to the Koch-Weeks bacillus and the pneumococcus that the majority of these cases of acute conjunctivitis are due. The Koch-Weeks bacillus possesses a higher degree of contagiousness than any other that can attack the eye. Out of 21 experimental introductions made by various authors on the human eye, 20 resulted in conjunctivitis; 15 cases where a pure culture was used were all attacked; in 6 cases a mixture was introduced into the conjunctival sac, and 5 of these were affected.

The clinical picture is simple. The eye first affected commences to burn and smart, and becomes slightly photophobic. The margins of the lids become slightly red and puffy. This puffiness seems usually more marked in the lower margin of the upper lid. The palpebral conjunctiva becomes greatly congested, very red and swollen, but usually retains a smooth surface. Only very rarely does one see any follicular enlargement in the fornices. The bulbar conjunctiva becomes of a uniform red colour. (In the picturesque language of the rank the disease is called "pink eye"). Later on, especially in adults, this becomes flecked with tiny little ecchymotic patches disturbing the uniformity of the pink. The bulbar conjunctiva usually shows only slight swelling or chemosis. Sometimes tiny swellings resembling phlyctenulæ develop at the corneal margin. In tuberculous children true phlyctenulæ may develop. Dr. Nias and I have shown that in these cases there is always a low opsonic index for tubercle, and some other evidence of tubercular infection. In the height of the inflammation there is usually a good deal of purulent secretion along the lid margins and in the angles of the eyes, and little flakes of pus float in the conjunctival sacs. The incubation period is from 24 to 48 hours, and consequently the two eyes are usually affected within three days. The organism is a thin bacillus about two-thirds of the length of the tubercle bacillus, and about the same breadth. It lies in clusters both extra-cellularly and intra-cellularly. It sometimes is found in the multilobular leucocytes in great numbers, and I have seen a desquamated epithelial cell with vacuolated, decrepit-looking nucleus crammed with the bacilli. These stain easily, and gram well.

The inflammation runs its course in from two to four weeks. Sometimes if untreated it tends to leave a chronic inflammation, in which there is follicular enlargement. If an attack confers any immunity at all it must be of a very temporary nature, as I have seen cases of children where a second attack came on within a very few months.

I do not pretend to distinguish between this form of acute conjunctivitis, and that due to pneumococcus. I believe that in the great majority of cases they are indistinguishable. The clinical picture I have given you of the one will serve for the other with some slight variations. The pneumococcal conjunctivitis is self limited, especially when it occurs in epidemic form. It is not so infectious. In epidemics it is mostly children that are infected. In severe forms it sometimes gives rise to membrane formation, but the membrane is never a true necrotic membrane. There is probably a greater tendency to the formation of phlyctene-like swellings at the limbus of the cornea, and in my experience a greater tendency to tiny ecchymoses. None of these points alone enable us to differentiate pneumococcal conjunctivitis from the Koch-Weeks form. The essential difference is in the course of the disease, which is self limited, reaching its climax in five or six days, and then resolving rapidly. This extremely interesting point has been made by Arenfeld, and has been confirmed by other observers, and you can see how it brings a pneumococcal inflammation in the conjunctiva into line with the inflammations set up by the same organism in other parts of the body. A second essential difference between the two organisms, though it does not affect the clinical manifestations, is that the Koch-Weeks bacillus is always pathogenic, while the pneumococcus is only a facultative pathogenic agent.

Fortunately, when we come to the question of treatment there is no need to differentiate between the two forms. The two essentials are efficient and regular cleansing with some simple aseptic lotion, and the destruction of the organisms and their removal along with the affected tissues and the replacing of the affected tissue by healthy tissue. In the use of a lotion the most important effect is the mechanical cleansing and irrigation. For this purpose the lotion should produce as little irritation as possible, should be used as warm as it can be with comfort, and should be used in no niggardly fashion. A weak boric acid lotion in most cases fulfils these requisites, but where it produces irritation as it sometimes does it is best to substitute normal saline. The comfort produced by the free use of lotions is probably almost entirely due to the freeing of the conjunctival sac from portions of desquamated epithelium and flakes of pus which act as irritants like any other foreign body. In mild cases this cleansing of the eye and the prescription of a simple ointment to prevent gumming of the lids is really all the treatment required. In more acute cases nothing can replace the salts of silver in efficacy, and for certainty and efficiency silver nitrate is still the best, and properly used is likely to retain its position.

We are dealing now with organisms whose action is deeper seated than the diplobacillus of Morax. They are not only surface livers. They get into the cells, and generally speaking their whole sphere of action is deeper. To rid the eye of them we have to employ some agent which will be able to attack them where they are most active. When we brush the eyelids with silver nitrate in a 1 per cent. or 2 per cent. solution what we first notice is, that a faint bluish white pellicle forms on the conjunctiva. This is due to the coagulation of the proteids of the cells by their conversion into albuminates of silver. This conversion means, of course, the setting free of a certain amount of free nitric acid, with the consequent great irritation which invariably follows painting with silver nitrate. In other words, then silver nitrate produces a coagulation necrosis in the surface cells. The conjunctiva immediately sets itself to get rid of this surface slough, and for the next two or three hours there is an increase in the amount of secretion from the eyes, and the eyes seem to feel even more gritty than before. The contained organisms are acted on at the same time as the cells, and are thrown off with the cells, and though some undoubtedly escape, the number has at least temporarily been greatly diminished, and the supply of toxins is diminished proportionately, with the result that the irritation caused by the toxins is very greatly relieved, and you get the frequent history that, within an hour or two of the painting, the eyes feel cooler and more comfortable than since the inflammation commenced.

In using silver nitrate then we must be fully cognisant of the results we wish to produce. As it is only the most superficial layers which are affected, it would be unwise to employ the silver nitrate in such strength as to affect the deeper lying tissues where there are no organisms, and it would be equally unwise to employ it before the lapse of a long enough interval to allow of a complete regeneration of new epithelium to replace that thrown off. The most serious danger in using it too strong or too frequently is that, by doing so, deep sloughs may be formed, which, when thrown off, may leave raw surfaces in opposition, and so give rise to adhesions which may become permanent. Such a result is not uncommon from over anxiety on the part of those in charge of a serious or important case. As a general rule I should recommend that an interval of at least 24 hours be allowed to elapse between any two successive applications of silver nitrate even in severe cases, and that any excess should be always removed or neutralised by salt solution at the time of application.

The great irritation caused by the use of silver nitrate has led to numerous attempts being made to replace the violently irritant inorganic acid by some non-irritant organic acid. Many of these preparations must be familiar to you all, such as protargol, collargol, and argyrol. My personal preference is distinctly in favour of argyrol, used in strengths varying from 10 per cent. to 25 per cent., and it is in this form that I always prescribe silver salts when I wish to give them to patients for home use. Argyrol is itself a silver albuminate, being a compound of silver with vitellin, the only pure crystallisable proteid, the crystalloid body found in the aleurone grains of wheat. Our friends the bacteriologists, arguing from their experiments made in little glass tubes, have asserted that argyrol has no germicidal effect, or at most very little. Clinically, and from personal experience of its efficacy I can assure them that in the human conjunctival sac it has a very beneficial effect. The probable explanation of the seeming discrepancy is that in the eye, especially the inflamed eye, we have metabolic processes going on, which *inter alia* allow the silver in the argyrol to be set free and to convert other proteids present into silver albuminates. The organic acids derived from the vitellin being of a non-irritating nature, argyrol is practically painless in its use. Unhappily, though they are useful allies, none of these preparations are substitutes for silver nitrate.

The remaining forms of conjunctivitis hardly come within the scope of my title, nor within the limits of your patience. Diphtheritic conjunctivitis is not a common affection. It only occurred six times in Arenfeld's list. It is almost invariably secondary to nasal diphtheria. There is always grave constitutional disturbance. The temperature is always raised, usually 101° or 102°. On everting the upper lid the palpebral surface is found to be covered by a membrane which requires some force for its removal, and which leaves behind it a raw bleeding surface. Obviously the treatment of such a case must be on the lines of the treatment of diphtheria elsewhere. It is said that such cases are only very rarely followed by palsies. Whether such is the case or not I am not in a position to give an opinion.

Streptococcal conjunctivitis also is fortunately not a common form. Like streptococcal infections elsewhere it may run a very grave course with serious constitutional disturbance. Its tendency to give rise to corneal complications is probably as great as in the case of gonococcus. The most hopeful line of treatment will probably be by means of vaccines. Treatment by anti-streptococcic serums has not been very efficacious. But vaccines prepared from the actual organisms may give more assistance in our future dealings with such cases.

In the cases in which investigation does not show the presence of any bacterium or only of those found in the normal conjunctiva, we must first regard the obvious physical causes, or chemical causes. When these have been excluded there remain certain possibilities. (*a*) The irritation may be due to the presence of some organism, which the means of investigation at our disposal have not enabled us to identify. This seems certainly to be the case in trachoma, and in some cases of infectious follicular conjunctivitis, possibly also in spring catarrh. (*b*) The possibility of an endogenous conjunctivitis: This seems undoubtely to have taken place occasionally in a generalised infection with the gonococcus, and we have to remember, in this connection, the fact that an early and an even severe conjunctivitis occurs in some of the acute exanthemata.

CONGENITAL TALIPES. (a)

By W. FEDDE FEDDEN, M.S., F.R.C.S.,

Assistant Surgeon and Lecturer on Surgical Anatomy, St. George's Hospital; Senior Surgeon to Out-Patients, the Victoria Hospital for Children.

My remarks concerning congenital talipes deal mainly with the treatment of the commonest variety—viz., equino-varus, and the methods which I have found most useful in attempting to cure this condition. It is a condition which is obstinate, and only yields with prolonged treatment, and which very frequently tends to relapse.

Other forms of congenital talipes must be treated on precisely similar lines, but I do not think time will permit of any special description.

The cause of equino-varus, I may say at once, is unknown. If you read through a treatise on orthopædic surgery, you will be surprised to see the number of theories that the mind of man has been capable of devising to account for this deformity, but no one of them alone fits in with every detail of the condition, and many of them are entirely hypothetical. I do not think we need waste time discussing them to-night, suffice it to say that the posterior and internal structures in relation to the ankle-joint and the structures on the inner side of the foot are ill-developed and shorter than they should be in proportion to the other parts.

Now I wish particularly to point out—simple as it may seem—that in equino-varus you have two distinct conditions to deal with—viz., the equinus and the varus; and a realisation of this fact is, I think, the essential point in the treatment of the condition, for I believe it to be absolutely essential for the successful treatment of the deformity that the varus should be cured before any attempt whatever is made to treat the equinus by division of the Tendo Achillis. My reason for this statement is that if the latter tendon is divided, free mobility at the ankle-joint is at once established, and any attempt to correct the varus is then expended almost entirely as a strain on the internal lateral ligaments of the ankle-joint instead of upon all the joints, tendons, and ligaments of the tarsus.

The varus deformity, it is worthy of note, occurs not only at the ankle-joint but also at the medio-tarsal joint, and, more than this, it affects every structure at the inner side of the ankle and tarsus, tendons, ligaments, and lastly the *skin*, and this last is quite an important element to consider in all cases of talipes, for it is only by prolonged treatment that the skin can become stretched, and it does not do to divide it or forcibly lacerate it, as the subsequent scar tissue would only increase the deformity.

The successful treatment of congenital talipes must therefore be conducted—(1) slowly, and in stages, and (2) by working on the most distal parts to commence with. In the case of equino-varus the first thing to do is to correct the varus at the medio-tarsal joint, then that at the ankle-joint, and, lastly, only when the foot is square with the leg is it then time to bring down the heel by division of the T. Achillis.

And now as to the carrying of these points into actual practice. First, at what age should the treatment be commenced? The answer is, undoubtedly—the younger the child the better. In fact, if equino-varus is present, the practitioner should commence the treatment as soon as the mother is satisfactorily through the third stage of labour.

In the first instance, in all cases the treatment should always be manipulative, unless the deformity is extremely marked. It is surprising what an amount of correction can be obtained in quite young babies by simple rubbing of the tense structures with olive oil night and morning, combined with manual attempts in the direction of correction, or, if possible, over-correction. In the course of time nature aids one's efforts in this direction owing to the straightening out of the neck of the astragalus, which in the young babe is set somewhat obliquely inwards; in fact, a slight degree of varus is normal in the new-born, and disappears as the child grows. Cases in which this is present to a degree somewhat more marked than that which can be considered normal may often be cured by manipulative methods alone, but if the condition is at all evident tenotomies in some form or another are most generally required. However, I think it is best to commence with manipulative treatment to see what amount of "give" is obtained, and after a while one or two more or less taut structures—fascial bands, tendons, ligaments, or what not—will be felt beneath the skin just below and in front of the internal malleolus.

Now is the time for a so-called tenotomy. In this particular small operation I confess that I never know quite what I am going to divide, or what I do divide in a small baby; but I enter a very small tenotome on the inner side of the foot and pass it deep to the tight bands, whatever they may be. These I divide freely from within outwards, until there is only skin left between the tenotome and my finger, which is making counter pressure on the outside.

Sometimes the tibialis anticus tendon, sometimes the tibialis posticus, sometimes both, are divided, together with bands of plantar fascia, and in some cases free arterial hæmorrhage follows; but I have never seen any trouble result from this, and never do more than apply a pad of dry gauze and a bandage.

The foot is then corrected as far as possible by forcible manipulation, and several unpleasant cracks may be heard, and the limb is fixed firmly to an outside splint, to which the foot is drawn by bandages and strapping.

Subsequently, in a day or so, when the puncture is healed, the mother or nurse must be instructed to continue the manipulation as before, rubbing the parts night and morning and everting the foot with the right hand, whilst firmly grasping the malleoli with the left. Again, after a time, other tense bands will make their appearance in the same neighbourhood, and will require division in a like manner—in fact, two or three of these so-called tenotomies may be required in a severe case of deformity before the varus can be fully corrected, and it is far better to do many small operations than to attempt too much at any one time, and also it is necessary to give time to permit the skin to stretch.

In the majority of cases, with suitable manipulative treatment in the intervals by the person who tends the child, combined with the division of any structure that becomes tense and appears to prevent the further unfolding of the foot, the varus can be fully corrected, and then—and then only—should the Tendo Achillis be divided and the heel brought down so as to correct the equinus position of the foot. If done at an earlier date, as I have said, the leverage action over the tarsal deformity is at once lost, and, as far as I have seen, you will then never cure the varus.

In bad cases I have generally found it necessary to divide the anterior portion of the internal lateral ligament of the ankle-joint. The anterior part of this, the deltoid ligament, I might remind you, passes forwards to blend with the spring ligament around the head of the astragalus, and also becomes attached to the tuberosity of the scaphoid. For this purpose I enter the tenotome deeply straight into the astragalo-scaphoid joint, and cut outwards, at the same time dividing the tense structures at the inner side of that joint.

The tension of the fore part of the deltoid ligament is, I believe, one of the most important, if not the most important, element which firmly resists correction of a bad varus deformity in a young child, and after such division forcible eversion of the foot is required, and may be accompanied by a loud crack.

As a rule, I do not employ any retentive apparatus at first, such as plaster of Paris or Scarpa's shoe, as I think such apparatus is apt to cause pressure sores if it is used to *maintain* a foot in a position which it will not itself easily fall into. Proper subsequent manipulation I believe to be far more efficacious, together with the application of an outside splint in the intervals.

In extreme cases where the above-mentioned measures do not permit of correction of the varus, it is almost certain there is fixed bony deformity, and these are the cases in which we can scarcely hope for a perfect cure. If the child be still young I believe that scraping out the centre of ossification of the astragalus to be the best measure calculated to give a useful foot. This is done in order that the resulting cartilaginous portion of the bone may assume a fresh shape by compression. I have not yet seen sufficient of this method to judge of its value, but it is quite certain that cases which can not be made to assume a normal position by division of soft parts alone will do so after cancellous bone has been scraped out of the centre of the astragalus.

(a) Read before the Harveian Society of London, Dec. 12th, 1907.

In extreme cases excision of the astragalus is an operation which has recently been largely practised, and I cannot say that I have ever seen what might be called a truly satisfactory result from it. True, the operating surgeon may speak highly of his results, and the foot may tend to assume a somewhat more sightly position, but the structures at the inner side of the foot remain exactly in the condition that they were previously, and a varus of the anterior portion of the foot invariably remains. Except in very extreme cases of deformity, and after honest attempts at treatment by other methods I am not in favour of removal of the astragalus, as I believe much improvement may be obtained by repeated division of tense bands, provided the case is seen sufficiently early in the child's career, and when it is ultimately decided that astragalectomy is necessary, the previous tenotomies will to a great extent have freed the inward turn of the parts in front of the medio-tarsal joint.

The older operation of division of all structures down to the bone on the inner side of the tarsus, allowing the incision to become a large open granulating wound, is now obsolete, and deservedly so. Anything that requires division can be divided subcutaneously, and the skin will stretch somewhat in the course of time.

The operation of removing a wedge-shaped piece of bone from the outer side of the tarsus, irrespective of the joints, still has a few advocates, and from what I have seen appears to be useless; the deformity usually remaining just as it was before. Moreover, such removal of bone converts the foot into more or less of a stump, instead of a pliable structure. This also applies to a very large extent to those cases in which the astragalus has been excised. In fact if astragalectomy has been performed and has failed, I think it is preferable to leave such cases alone, and not subject them to any further excisions about the tarsus. They must either continue with their deformity or part with the foot.

Finally, the way to be successful with any congenital talipes is without doubt to get the case at the earliest possible moment, and to give personal supervision over a lengthy period, coupled with the services of an intelligent nurse, who will properly carry out the instructions *re* manipulation, etc. It must also be remembered that cases show a marked tendency for the deformity to recur if they are not being carefully watched, and once the proper correction has been obtained it is necessary to see that any tendency to recurrence is not again permitted.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

TUBERCULOUS DISEASE OF THE WRIST. — MR. WILLMOTT EVANS operated on a man, æt. 55, who had been admitted suffering from tuberculosis of the wrist for more than 18 months. He had a swelling of the wrist, with pain and inability to use it. When seen he had a swelling most marked on the dorsum, extending for a short distance above and below the wrist; it was soft, and gave a sensation resembling fluctuation. There was a further swelling which existed just above the knuckle of the forefinger, evidently containing liquid, and which was almost translucent. A diagnosis of tuberculosis of the wrist was made. The patient also had, though he was not aware of it, a swelling in the right iliac fossa, rounded and firm. No definite fluctuation could be obtained in it. A diagnosis of chronic abscess in connection with disease of the ilium or sacro-iliac joint was made. It was decided to operate on the wrist first. The lower semi-translucent swelling was incised and found to be a tuberculous ganglion in connection with the extensor tendon. It was emptied, and as much of the sac wall as possible removed. The swelling of the wrist was incised in two places, on the inner side from the head of the ulna to the base of the fifth metacarpal bone, and on the outer side directly from the middle of the lower end of the radius to the interval between the second and third metacarpal bones. The tuberculous material was evacuated, and the bones of the carpus were removed, together with a portion of the diseased adjoining bones. No attempt was made at a set excision, but, so far as possible, all the diseased tissue was removed. The cavity was scraped with a sharp spoon, and then it was filled with the following powder: Sulphur, 1 part; boric acid, 7 parts. Drainage tubes were then inserted, and the wound was dressed, the hand and forearm being placed in a splint. The iliac abscess was opened a fortnight after the other operation, an incision being made parallel to and just above Poupart's ligament. By careful dissection it was found possible to open the abscess without injuring or even seeing the peritoneum. A large amount of pus was evacuated, and then a probe having been introduced, it passed backwards and inwards to the right sacro-iliac joint. The wound was drained and dressed. Mr. Evans remarked that the treatment of tuberculous wrist was often unsatisfactory, whatever form of operation was adopted; but he had found the best results from opening the joint where the swelling was greatest and removing all the damaged tissues as far as possible without attempting to follow the lines laid down in books on operative surgery. The extent of disease was not alike in two cases, and the amount of tissue removed must depend on the amount of disease present. It was never advisable, he thought, to leave any of the carpal bones, but the amount to be removed from the radius and ulna and the bases of the metacarpus varied greatly. He also attached great importance to filling of the wound with a sulphur powder. Sulphur thus diluted was an exceedingly good antiseptic, especially for tuberculous conditions, and yet it was not liable to give rise to any sloughing of the tissues such as may be produced if undiluted sulphur be employed. It tended to produce a healthy condition of the walls of the cavity, and favoured rapid healing. With regard to the iliac abscess, it was obviously necessary to drain it, but from the source of the suppuration—namely, tuberculous disease of the sacro-iliac joint—it was clear that the prognosis was bad. For the first few days there was much discharge, but the amount of this rapidly diminished, and in about three weeks from the time of operation the wrist wounds were healed. It was then found that the hand had slipped a little forwards, so a splint was ordered to hold the hand in its right position. A very successful result followed, and the movements of the fingers greatly improved. At the time of the patient leaving the hospital there was still some discharge from the iliac wound, but the man's general health had greatly improved.

OUR Edinburgh correspondent refers in another column to the retirement of that eminent alienist, Dr. Clouston, as Physician-Superintendent to the Royal Asylum. His whole medical career for nearly half a century has been devoted to work among the insane, and he will be greatly missed in the direction of affairs at that model institution. We are glad, however, to learn that, although retiring from the active duties of the post, his advice and assistance will still be at the disposal of Edinburgh's citizens.

TRANSACTIONS OF SOCIETIES.

HARVEIAN SOCIETY OF LONDON.

Ordinary Meeting, held December 12th, 1907.

The President, Dr. Sidney Phillips, in the Chair.

Mr. Leslie Paton, F.R.C.S., read a paper on

THE DIAGNOSIS AND TREATMENT OF SOME COMMON FORMS OF CONJUNCTIVITIS.

(This paper will be found in full on page 66 of our present issue.)

Before reading the paper, Mr. Paton showed several micro-photographs of organisms found in the commoner forms of conjunctivitis.

The paper was discussed by the President, Sir John Broadbent, Mr. Crisp English, and Dr. Fowler.

Mr. W. Fedde Fedden, F.R.C.S., read a paper on

CONGENITAL TALIPES,

which will be found on page 69 of our present issue.

Mr. Jackson Clarke discussed the paper, and also showed a case of talipes equino-varus.

Mr. Laming Evans agreed with Mr. Fedden that the varus deformity should be corrected before the equinus in all cases; he advocated that the supination of the posterior tarsal bones should be corrected at the same time as the adduction of the anterior tarsal bones. He showed casts, before and after treatment, of a severe case of congenital equino-varus in a child of 4, with marked bony deformities, which he had treated by tenotomy, manipulation, and a modified Scarpa's shoe. Although such treatment entailed much time, the result was a more elastic and supple foot than if treated by excisions. He showed also casts, before and after treatment, of a severe relapsed congenital equino-varus in a man of 18; he had treated this case by preliminary tenotomy, fasciotomy, manipulations, and retentive apparatus, until the greater part of the adduction and supination was corrected, and by subsequent excision of cuboid and partial excisions of os calcis, head and neck of astragalus and scaphoid. The result was a more shapely foot than after astragalectomy, with the varus deformity completely corrected, and a more supple and elastic foot than after a cuneiform resection without preliminary correction of the varus. In some cases he had found a partial enucleation of the astragalus useful, and showed a photograph of a boy of 12, in whom he had corrected some residual equinus by dealing with Nélaton's præ-peroneal tubercle in this way.

WEST LONDON MEDICO - CHIRURGICAL SOCIETY.

Clinical Evening, January 3rd, 1908.

The President, Mr. Richard Lake, F.R.C.S., in the Chair.

The following cases were shown:—

Dr. Seymour Taylor.—A man, æt. 59, with dysphagia, caused by an aneurysm of the third part of the aortic arch. None of the cardinal signs of aneurysm were present, but a bougie was obstructed 12 ins. from the incisor teeth, and a skiagram showed the tumour. There was also extensive calcareous degeneration of the arteries.

Mr. Percy Paton.—A man, æt. 47, with epithelioma of the floor of the mouth, attached to the jaw, also involving the tongue and lymphatic glands.

Dr. Phineas Abraham.—(1) An unusual form of tinea circinata on the wrist of a girl associated with impetigo contagiosa. (2) A large hairy nævus involving the greater part of the left side of a male infant, æt. 18 months. (3) A case for diagnosis. An excavated ulcer at the left outer canthus of a boy, æt. 5, with greatly enlarged and indurated glands of the same side of the face and neck; six weeks' duration. (4) Four bald-headed children; the condition caused by X-rays applied three months ago for the cure of ringworm.

Mr. Sampson Handley.—(1) A woman upon whom he had performed gastrostomy and excision of the larynx and part of the pharynx for epithelioma. (2) A woman whose breast has been excised for extensive carcinoma.

Mr. Aslett Baldwin.—A man, æt. 30, after removal of breast for carcinoma. The patient was shown at the last clinical evening two months ago. There was then a deeply ulcerated growth in the situation of the right breast, with secondary growths in the skin and enlarged axillary glands. The breast, sternal part of the pectoralis major, the deep fascia from close to the clavicle, in front of the sternum, 2 to 3 in. below the xiphoid cartilage to posterior boundary of the axilla, together with the axillary lymphatic glands, had been removed. The patient is now doing his full work as a butcher, and can raise his hand and arm vertically above his head without difficulty. (2) A girl, æt. 1 year 8 months, with what is probably a sarcoma starting in the left maxillary antrum. There is great prominence of the left eye, and depression of the palate on the same side; also a large swelling in the right temporal region. Mercury has caused no alteration in the growths, which are steadily increasing in size. They were first noticed on December 17th. (3) A man, æt. 71, with an epitheliomatous ulcer on the left side of the tongue and tonsillar region.

ULSTER MEDICAL SOCIETY.

Meeting held Thursday, January 9th.

The President, Dr. John McCaw, in the Chair.

HOSPITAL ABUSE.

Mr. Fullerton called attention to the question of hospital abuse in Belfast, specially with regard to the Royal Victoria Hospital, and moved that a special meeting of the Society be called to consider the subject. After some discussion, it was agreed that a joint meeting of the Ulster Medical Society and the Ulster Branch of the British Medical Association should be held, and that all medical practitioners in the district should be invited to attend.

Dr. Cecil Shaw gave a short account of Paterson's method of removing papillomata from the larynx in children, and showed the tube spatula and long forceps used. He pointed out the objections to laryngotomy, and referred to two cases in which he had done this operation, and which he had exhibited at the Society. After using the instruments shown on two occasions lately in a case of papilloma in a girl of 13, he had no hesitation in recommending this procedure in preference to laryngotomy.

Mr. Robert Campbell read notes on three cases simulating perforating gastric ulcer, and showed a malignant pyloric tumour removed by operation. The cases simulating gastric ulcer, in all of which the abdomen had been opened, had turned out to be appendicitis in one, adhesions between the liver and pylorus in the second, and acute hæmorrhagic pancreatitis in the third. In speaking on the paper, Mr. Fullerton said that he had had one case similar to Mr. Campbell's third, in which also he had operated, expecting to find a perforated gastric ulcer.

Mr. R. J. Johnstone read a short paper on "Renal Decapsulation for Puerperal Eclampsia." The patient on whom Mr. Johnstone operated was having a fit every 20 minutes by the watch. He gave a third of a grain of morphia, and large amounts of saline by the bowel, and decapsulated one kidney. The urine, which had been about 2 oz. in 24 hours, rose to about 20 oz. Full details of this most interesting case will be published later, as this is the first time that decapsulation has been done for the relief of puerperal eclampsia.

Dr. A. G. Robb read a short paper on the use of Flexner and Jobling's serum in the treatment of cerebro-spinal fever. The Belfast epidemic, running into several hundreds of cases, began early last year, or rather at the end of 1906, and during nine months the mortality in hospital was 70.4, and outside hospital 74.7, figures which correspond closely with those of other epidemics elsewhere. Several different serums were tried during this period, but none had any perceptible effect. From September to December, all cases treated in hospital, 32 in number, were injected with

Flexner and Jobling's serum, and the mortality in this group of cases was 26.6. During the same period about an equal number of cases were treated outside hospital, and, according to the figures supplied by the Medical Officer of Health to Dr. Robb, the mortality among these was 87.5, showing that the type of disease had not altered. The serum was obtained from the Rockefeller Institute of Preventive Medicine in New York. Dr. Robb said that it was too early to draw definite conclusions, but the results so far were encouraging.

Dr. THOS. HOUSTON said that, tested in the Pathological Laboratory at Queen's College, this was the only one of the various serums which Dr. Robb had tried which produced any agglutinating effect. He attributed its apparently greater power partly to the fact that it was not injected subcutaneously, as the others were, but directly into the spinal cord.

GLASGOW NORTHERN MEDICAL SOCIETY.

MEETING HELD TUESDAY, JANUARY 7TH, 1908.

Dr. CAMPBELL MARSHALL in the Chair.

Dr. T. K. MONRO introduced a discussion on the TREATMENT OF CHRONIC RHEUMATOID CONDITIONS.

Dr. MONRO said that rheumatoid arthritis, chronic rheumatic arthritis, rheumatic gout, arthritis deformans, arthritis nodosa, nodosity of the joints, and osteo-arthritis are some of the names that have been applied to a group of joint affections, but for purposes of discussion it would be necessary to distinguish half a dozen types, the first three of which would come under the designation of rheumatoid arthritis and the last three under that of osteo-arthritis.

The first two types involve the smaller joints, such as those of the hand, occasionally the larger joints. The first of these two types is acute, and difficult to distinguish from ordinary acute rheumatism. The second is chronic, and is associated with striking wasting of the inter-osseous muscles of the hand and distortion of the digits. The disease in both types affects the synovial membranes and soft tissues about the joints. The third type affects children before the second dentition, and is associated with enlargement of the lymphatic glands and spleen. It runs a chronic course. The fourth type is the localised osteo-arthritis often confined to a single joint, *e.g.*, the hip, when it may be accompanied by obstinate sciatica. Here the cartilages, bones, and synovial membranes suffer alike. The fifth type consists of Heberden's nodes. The sixth type is constituted by some cases of spondylitis deformans, or rigidity of the spinal column, when this is due to osteo-arthritis. Chronic polyneural rheumatoid arthritis is occasionally due to infection from a septic focus such as an ulcerating pile or pyorrhœa alveolaris. The treatment of such conditions is essential in treatment of the joint affections. Diet in those cases should be generous, both in quantity and quality; further, carbohydrates and fats (cream, butter, and cod liver oil) are useful. Rest is necessary as long as there is pain, and patients often improve very much after long periods in bed. Of drugs guaiacol carbonate, arsenic, and iron are useful. For pain salicylate of soda in small doses, aspirin, and occasionally opiates are good. Locally much relief comes from the application of methyl salicylate under gutta-percha tissue. Tallerman's hot air bath inducing active hyperæmia, and Bier's passively induced hyperæmia may be useful. After the acute symptoms pass off passive movements prevent the formation of adhesions. The waters and baths of Bath, Buxton, Harrogate, etc., are useful in convalescence. The treatment of osteo-arthritis is much the same as that of rheumatoid arthritis, but great care is necessary in the use of passive movements. In chronic articular rheumatism guaiacum and sulphur with iodide of potassium, iron, and arsenic should be used in conjunction with a generous diet. Though the microbic theory of the origin of rheumatoid arthritis is still improved, there are joint affections undoubtedly due to a microbe, notably gonorrhœal rheumatism. Here the important point is to cure the original lesion, and then proceed to neutralise the tendency to fibrous adhesions by the use of iodide of potassium, guaiacum, etc.

A discussion of a general nature followed, taken part in by the President, Dr. John Donald, and Dr. John T. Maclachlan.

Dr. DONALD thought the X-rays might be taken advantage of in the shape of mild local applications round the affected joint.

Dr. MACLACHLAN considered it was not an easy matter to differentiate the various morbid affections, embraced by the term chronic rheumatoid conditions. In his experience he had found the persistent use of iodide of potash with a proteid dietary, in which starchy and saccharine materials were reduced to a minimum, give in some cases satisfactory results.

LIVERPOOL MEDICAL INSTITUTION.

AT the annual meeting, held on January 9th, the following list of officers and members of Council was adopted:—President: *T. H. Bickerton; Vice-Presidents: F. Charles Larkin, R. W. Murray, *Hugh E. Jones, *C. Thurstan Holland; Treasurer: Robert A. Bickersteth; General Secretary: J. E. McDougall; Secretary of Ordinary Meetings: *R. J. M. Buchanan; Secretary of Pathological Meetings: *D. Douglas-Crawford; Librarian: W. B. Warrington; Editor of the "Journal": John Hay; Council: W. N. Clemmey, William Crooke, Charles A. Hill, W. B. Paterson, Thomas Stevenson, Joseph D. Wright, *Frank T. Paul, *John Ambrose Cooke, *Henry Halton, *W. Blair Bell, *Joseph F. Blood, *Hubert Armstrong; Auditors: *G. P. Newbolt and *J. Lloyd Roberts. (Those marked * did not hold the same office last year.)

CORRESPONDENCE

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Jan. 12th, 1908.

THE MODERN TREATMENT OF CONSUMPTION.

THE tuberculin of Koch, T.O., says Prof. Rénon, had been abandoned in France for a long time. It has continued to be used, however, abroad, especially in sanatoriums, where each author has his methods, injecting doses which, in Prof. Rénon's opinion, are too large.

In this country a few attempts have been made to take it up again. M. Guinard notably, has utilised it in the sanatorium at Bligny, but in exceeding small doses. He begins by injecting 1-250 of a milligramme, gradually increased to 1-20 milligramme.

He operates very slowly and at intervals so as to avoid any reaction, rise of temperature, loss of strength, or a sensation of fatigue. M. Guinard thinks that, administered with the above precautions, tuberculin can give good results in apyretic forms and in torpid consumption. I am of the same opinion, and the question has been submitted to the Special Committee on Tuberculosis, but it will take four years at least before we can have a precise idea of the therapeutic value of tuberculin.

Among the other tuberculins that of Denys, of Louvain, has been employed in the sanatoria of Switzerland, Belgium, and the North of France with variable results. At the last Medical Congress M. Stella made a communication in favour of this tuberculin, and showed himself very enthusiastic over this method. But he was opposed by Dr. Béco, of Liège, who asserted that he had studied the tuberculin of Denys for six years in the hospital on over 100 patients without obtaining any satisfactory result that could be attributed to the tuberculin.

Dr. Berauck, of Neufchâtel. has invented a tuberculin, which is much used in Switzerland. M. Bauer reported at the Medical Congress 150 cases of patients treated by this method with good results, and Prof.

Sahli, of Berne, who is a partisan of this tuberculin, said that it should be used in very small progressive doses. The treatment is difficult and long, requiring a large sum of patience and trouble, both on the part of the patient and the physician.

It is only applicable to a limited number of cases, and frequently has to be abandoned.

Such is the so-called specific treatment of tuberculosis by serums and tuberculins, but in reality no specific treatment has yet been found. However, it can be affirmed that every new method, provided it is inoffensive, is sure to give satisfactory results. The old saying, "take the medicine while it cures," expresses an absolute truth. If we were to compare one with the other the results obtained by the different anti-tuberculous treatments, we would find that they all obtained the same percentage of improvement, of cures, of stationary conditions. Any treatment imposed by a medical man who has faith in his therapeutic method develops in his patient the same faith. The patient allows himself to be influenced by the optimism of his doctor, and for a time a real improvement does take place. It is well known that any phthisical patient who changes his treatment or his doctor feels much better for two or three weeks.

Do we possess action on the parasite of tuberculosis? No, not at present, at any rate.

Can we obtain an anti-tuberculous vaccine? No, since our only hope is in the tuberculin of Koch employed according to a new posology not yet established.

Do we possess action on the organism in general? Yes, by making the patient live in air as pure as possible, by repairing the waste of tissue, by recommending substantial food, by stimulating the appetite, and by prescribing an active medical treatment.

The diagnosis of phthisis should be made as early as possible, and for that account should be taken of every sign, hæmoptysis, wasting, loss of strength, etc., that would suggest the existence of tuberculosis in its initial stage.

We found great hopes, at this present time, on ophthalmo-reaction. I tried it on 28 patients in my hospital service; 15 cases gave positive results. Three of these reactions were particularly intense. In one case the conjunctivitis persisted six weeks, a second patient presented a slight keratitis, and a third an interstitial keratitis with iritis, which lasted three weeks. The tuberculin solution I had employed was 1 — 100. Perhaps if I had used a weaker solution such accidents would not have occurred.

In any case, every eye on which the reaction is tried should be treated by an occlusive aseptic dressing, and in case of intense reaction taking place, a drop, three or four times a day, of the following solution should be placed between the eyelids:—

Argyrol, 3 gr.
Water, 2 dr.

The treatment of consumption should not be systematic; it should be adapted to each case on its special merits.

As to the prognosis of phthisis, a great reserve should be observed. Medical men believe too easily in the cure of consumption, which facts do not justify. Tuberculous patients might be divided into three classes: those who are but slightly predisposed to the disease, and who either get well naturally or with a little care. In the second class might be included those who have a more marked predisposition, presenting indisputable clinical lesions, and even fever. These can be cured if they are treated in time with intelligence, devotion and tenacity. But for many of them the cure is not permanent. With a great deal of care an "armistice" of a certain length of time may be obtained, but the enemy is not disarmed, and prepares for a new attack. These patients may seem to be cured, but they drag on an existence different to all others; their life is very fragile. In the third class might be placed those patients who are very much predisposed to the malady, and who present bacilli of a very virulent type in their expectoration. These will not get well, no matter what is done for them. Daremberg says that a third of tuberculous patients begin their malady by the last stage; they are irrevocably condemned.

When, consequently, one is called to express an opinion on the prognosis of the disease, one should not conceal from the family of the patient the extent of the sacrifices to be made in order to obtain a result, for even in the most favourable cases tuberculosis requires two or three years of intelligent, assiduous and devoted treatment.

Coxalgia.

At the last meeting of the Académie de Médecine, Prof. Lannelongue laid down the rules that should be followed in the treatment of coxalgia: Rest in the horizontal position, with continued extension of the limb; apparatus made of plaster or silicate should be proscribed, as they do not correct, in general, vicious attitudes, and compromise the future movements of the limb. At the same time as the continued extension, intra and extra articular injections should be made with substances, such as iodoform, ether, and creosote incorporated with oil:—

Olive oil, 3 oz.
Ether, 1½ oz.
Iodoform, 2 dr.
Creosote, ½ dr.

The ether spreads the iodoform over the whole internal surface of the joint—fungosities, cartilaginous ulcerations, etc. The iodoform arrests the noxious effects of the bacilli, and favours the healing of the tuberculous lesions already produced, while the creosote possesses a sclerosive action. Treated by this method at the outset of the malady, the patients have every chance of being cured.

GERMANY.

Berlin, Jan. 12th, 1908.

At the Hufelandische Gesellschaft Hr. v. Hansemann spoke on

Carcinoma of the Prostate.

It showed many peculiarities. The first preparation shown was from a young man, æt. 21. (?) What was remarkable was that the tumour had reached such a size and set up such manifold disturbances that a diagnosis could be reached from the clinical symptoms alone. The most frequent form was that of very small tumours, in which the prostate did not appear to be enlarged, and was not the seat of any symptoms, nor was it nodular and hard. On the contrary other symptoms made their appearance, which were of a diffuse nature, so that one had no suspicion that the case was one of cancer. Cancers of the prostate were more frequent than had been supposed. In the Virchow Hospital there had been four cases in 400 autopsies. Since that time careful microscopical examination had been made of the prostate with the surprising discovery that the percentage of carcinoma was much higher than had been thought. The speaker believed that 21 per cent. of carcinoma cases had hitherto escaped detection in previous examinations.

The clinical symptoms were dependent on the presence of metastases. Carcinoma of the prostate was often associated with bony metastases, as was first pointed out by Recklinghausen. It was an osteoplastic carcinoma in which bone masses were deposited, in which the spongy bones, and especially the bodies of the vertebræ were eburnated. These bodies of the vertebræ became enlarged, and pressed on the spinal cord so as to set up the symptoms of a myelitis.

It was different in a case of osteosarcoma in which the bone was destroyed, where in the skeleton loculi were found as if they had been punched out with an iron. In the case shown the osteosarcoma was more of a fibrous nature; it started from the bony tissue itself. It was different from a true myeloma. The skeleton of the trunk reminded one of osteomalacia; the softening had been caused, however, by innumerable tumours that had eaten into the bones.

Hr. Stauss had observed a patient whose sufferings had presented the appearance of spinal caries. The autopsy showed, however, that the vertebral column was filled with a number of small carcinomata of sizes from that of a bean to a cherry, which had had a destructive tendency. At the uppermost point of pain, where the speaker had heard a crackling when the patient sat up, there was a dislocation of the vertebra. Along the whole course of the large bronchi a fine yellowish grey mucus was present, which proved to be cancerous.

Hr. v. Hansemann thought the case related was both interesting and typical. He had himself observed several cases of the kind. They almost always went under the name of tuberculosis. Post-mortem examination showed the true nature of the disease. As they were sometimes associated with tuberculosis the diagnosis was difficult. But if tuberculosis broke out in a man over 60 years of age there was mostly a cancer at the back of it.

Sometimes we saw cases of putrid bronchitis, and there it might be that the real cause was carcinoma of the œsophagus. Cancers of the stomach also occasionally gave rise to no symptoms.

Hr. Ewald confirmed the occurrence of such latent carcinomata of the stomach and gullet.

At the Laryngological Society Hr. Alexander showed a female, æt. 20, who had suffered from hoarseness from her earliest childhood. On examination of the larynx both vocal cords were seen to be split in their ligamentous parts into apparently an upper and a lower lip. The deep base of the split showed a gray white. Whether there had been some ulceration at one time followed by epidermisation of the base, instead of cicatricial contraction, it was hard to say. After failure of all kinds of treatment methodical vocal exercises were going to be tried.

Hr. Schoetz said he had shown a somewhat similar case to the society in which, however, there was certainly no ulcerative process, but a paralysis of muscle. It looked like a case of necrosis of epithelium such as was seen after influenza.

Hr. Grabower suggested that aberrant cartilage cells had prevented cicatrisation. Hr. Ed. Meyer thought the condition was a congenital one.

AUSTRIA.

Vienna, Jan. 12th, 1908.

VAGRANT PLEURITIC EXUDATION.

SCHROTTER and Weinberg presented a peculiar case of pleuritic exudation. Three years ago the patient had right-sided pleuritic effusion, which had been aspirated several times with the object of curing the patient, but apparently without effect.

At the present time the fluid is, when the patient is sitting in bed, as high as the angle of the shoulder-blade, the fifth rib in the axilla; but when in the lying posture the fluid in the latter is in the fifth intercostal space. The exudation seems perfectly fluid and mobile. With the Röntgen rays this mobility of the fluid is easily traced, and more clearly when the patient is turned on the left side, when the whole fluid falls towards the mediastinum, leaving the costal surface free. The lung and diaphragm appear healthy, the former expanding on the descent of the diaphragm. Schwarz asked if the fluid had been carefully examined. Weinberg replied that it had a straw colour, although slightly cloudy, with a sp. gravity of 1018; with nitric acid a heavy flocculent deposit was thrown down, and the presumption was formed that tubercle was the basis of the pleuritic effusion.

Pius related a case of pericarditis which he had under his care for some time that acted in a similar manner, pressing on the lower lobe of the lung, and producing similar infiltration in the pleura which closely simulated pleuritis.

ARSENIC AND AUTOLYSIS.

Hess and Saxl gave an elaborate description of their investigations and experiments with arsenic and organic matter. When arsenious acid was added to organic matter and placed in the incubator it remained longer sterile and better preserved than with any other antiseptic, such as tolu oil water. This observation and the knowledge of preserving bodies inspired the idea that the autolysis was checked by the arsenious acid by some specific action.

To prove this it was necessary to take a portion of the liver of a newly-killed guinea-pig and weigh it into several equal parts, each placed in test tubes, with equal quantities of sodium chloride solution. The liver was broken up into very fine divisions, and to one of these test tubes was added 5 ctms. of arsenious acid solution containing 1.5 in 1,000. The other test tubes had 2 ctms. of tolu oil added. The test tubes were all closed, well shaken, and placed in an incubator, and after one, two, five and eight days carefully examined to see that sterility was produced. The post-mortem exhaustion of the albumen or autolysis was accomplished according to Schliesinger's method, which was entirely checked by the presence of arsenious matter, but the other test tubes autolysed as in the normal organ. It was found later, however, that the arsenious test tube autolysed also, which proves that the arsenious acid is only temporary and not permanent, thus neither destroying the cells nor injuring the albumen, but only the ferment, as the proteolysis ultimately proceeded unhindered to a normal finish. Further experiments of this autolytic ferment were made on trypsin, pepsin, and erepsin with large quantities of arsenious acid, but the results were negative; hence they concluded that autoxyl and cacodyl checked the hepatic autolysis. There is only another substance which has the same specific action on this autolytic ferment—viz., hydrochlorate of quinine, both of them may be termed anti-protozoic, or economisers of albumen. This may form a rational explanation for the use of arsenic in the case of tumours or excrescent growths in opposition to phosphorus, which encourages or favours autolysis. There is still another anomaly to be accounted for in the final product of arsenic and phosphorus, both of which produce a fatty condition of the cell and require further elucidation. Reicher thought these results were in opposition to Ascoli's, but Saxl said that Ascoli used arseno-tri-sulphide, which favoured the autolysis. Schrötter thought the use of arsenic in the growth of malignant neoplasms was very limited. Téleky recommended subcutaneous injections of arsenic, as it was more readily absorbed by the swollen lymphatic glands and more effectual in its action.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

EDINBURGH.

RETIREMENT OF DR. CLOUSTON.—Dr. T. S. Clouston has resigned his position as Physician-Superintendent of the Royal Asylum, Edinburgh. His retirement is an event of great importance, not only to the institution he has done so much to develop, but to the interests and reputation of all matters connected with lunacy in Scotland. Dr. Clouston's whole medical career of nearly half a century has been devoted to work among the insane. He acted as assistant physician at Morningside Asylum under Dr. Skae from 1860 to 1863, when he was appointed Superintendent of the Cumberland and Westmoreland Asylum, Carlisle, and continued in that office for 10 years, until in 1873 he succeeded Dr. Skae as head of Morningside Asylum. He at once proceeded to throw himself into the task of reconstructing the asylum, and as he himself phrases it, the building "has seldom been out of the mortar pot" since. However, the process of rebuilding culminated some 15 years ago in the opening of Craig House, which provides accommodation for the higher paying class of private patients, and in respect of situation and construction, is probably unrivalled by any similar institution. During the past 35 years £180,000 has been expended on building. At the date of Dr. Clouston's appointment the annual income from the better class of private patients was £8,600; at the present time it is £35,000 a year. The great prosperity of the asylum has depended not only on Dr. Clouston's reputation as an administrator, but on his remarkable personality, and there is no doubt that his really immense success in the treatment of the mentally sick, as well as his very extensive consulting practice, were due to a large degree to the faculty he has of throwing himself heart and soul into the business of the moment, and the confidence he inspires both in patients and friends. As the University Lecturer on Psychiatry the same impressive personality had full scope, and his lectures were invariably popular, well attended, and full of practical hints. His lectures were mostly clinical, and he utilised the material in the asylum to the best advantage. Dr. Clouston's retirement from active work at Morningside does not, we understand, involve his withdrawal from this post. His activities have been multifarious, and his opinions on medical and other matters of public interest have always commanded the respectful attention of his fellow citizens. He has a remarkable faculty of educating and leading public opinion, and is a lucid exponent of the views which he wishes to promulgate. Greatly therefore as his loss will be felt at the Morningside Asylum, his fellow citizens have the satisfaction of learning that he is still resident in their midst, and that his public spirited assistance and advice will still be at their disposal.

Edinburgh Royal Infirmary.—At the annual meeting of the court of contributors, held on January 6th, for the purpose of considering the annual report of the institution, the Chairman referred to the question of providing wards for the treatment of mental disease. The managers, he said, had a scheme prepared, which they were ready to go on with as soon as funds permitted. The addition of such a department meant a cost of between £60 and £70 per patient, and an increased cost of £1,500 per annum. Mr. Mackenzie suggested that the managers ought to look into the matter of the use of the institution by persons who were not sick poor. He suggested that a charge might be made to people who were able to pay it in return for the advice they received.

Dr. G. E. Cartwright-Wood, a son of ex-Provost Wood, Portobello, has been appointed bacteriologist to the Metropolitan Asylums Board, Belmont. He graduated M.B., C.M.M. 1875, and B.Sc. in natural science in 1887. He studied experimental pathology in Edinburgh and Germany, and chemistry at Wiesbaden. Later he worked under Hueppe, of Prague, and has made investigations in various branches of bacteriology. He recently held the appointment of bacteriologist to the laboratories of the Royal Colleges of Physicians and Surgeons in London.

GLASGOW.

Complimentary Dinner to Sir George Beatson, K.C.B., M.D.—A large turn-out of members of the medical profession assembled in the Grosvenor Restaurant, Glasgow, on January 10th last, to do honour to Sir George Beatson, in recognition of the high distinction conferred on him by His Majesty the King. Sir George recently had conferred upon him the K.C.B., in recognition of his eminence as a Surgeon to the Western Infirmary, the Cancer Hospital, and his pre-eminent services to St. Andrew's Ambulance Association, of which he was one of the founders. This Association has now granted certificates of proficiency to 47,000 pupils. Sir George, as Chairman of the Council, was chiefly instrumental in the equipment and despatch of the Scottish National Red Cross Hospital to the South African War. In 1888 Sir George originated the Volunteer Medical Staff Corps in Glasgow, and now commands five companies in the Glasgow Division of the Royal Army Medical Reserve Corps. Sir George is at present engaged in the equipment of the Queen's Victoria Hospital for the Sons of Sailors and Soldiers. His services have likewise been requisitioned in connection with the new Territorial force. His Grace the Duke of Montrose was in the chair, and proposed Sir George's health, recalling his public services in graceful terms. Sir John Ure Primrose proposed the toast of "The Medical Profession," responded to by Professor Sir Thomas McAllen Anderson and Professor Chiene, Edinburgh. Among those present were Sir Hector Cameron, Professor A. R. Simpson, Professor Glaister, Dr. Byrom Bramwell, Dr. Allan Jamieson, Dr. D. J. Macintosh, M.V.O., Dr. J. Mantone Thom, the respective Medical Superintendents of the Western and Royal Infirmaries, Professor Cunningham, Dr. Underhill, and many other well-known medical men and citizens of the west. Dr. Robert T. Halliday had charge of the arrangements.

Infectious Disease in Glasgow.—Owing to the prevalence of measles, the Glasgow and Govan School Boards have extended the Christmas holiday from the usual period of ten days to three weeks. A considerable outbreak of typhoid fever in the fashionable residential quarters of the city has also caused some disquiet. The first cases were notified in Christmas week, and since then others have occurred in rapid succession. The epidemic has been traced to an infected milk supply from a farm on the outskirts of the city. A young woman was found to be lying ill there with what was at first suspected to be pneumonia, but afterwards was found to be enteric fever. The Medical Officer of the City has taken every precaution, but it is feared that other cases may occur, as the incubation period of the disease has not yet been passed.

BELFAST.

Public Health.—The death-rate in Belfast continues abnormally and disgracefully high, having been 28 last week. That there is no great amount of infectious disease is shown by the fact that there are only 45 patients in Purdysburn Fever Hospital, including 9 typhus and 8 cerebro-spinal fever. The question of opening dispensaries for tuberculosis having been raised in the Corporation, the Lord Mayor (the Earl of Shaftesbury) has suggested that it might be more desirable to enter into a supplemental arrangement with the authorities of the Forster Green Hospital for Consumption for working their dispensary, and so effecting a considerable saving to the Corporation. The arrangement already made between the Corporation and the hospital is for the enlargement of the hospital and the treatment in it of a certain number of patients sent by the Corporation. The Lord Mayor and the Chairman of the Public Health Committee for the time being are to represent the Corporation on the Board of the Forster Green Hospital. Lord Shaftesbury's suggestion will no doubt receive favourable consideration, for any proposal to open new dispensaries would meet with considerable opposition. The poor general practitioner has already to contend with sufficiently numerous institutions supplying free treatment without the Corporation adding to their number. On the other hand, the public has been so stirred up by the recent Tuberculosis Exhibition that it is anxious at any cost to do something, and in a mood to do something foolish rather than nothing at all.

LETTERS TO THE EDITOR.

THE *STAR* AND THE MEDICAL PROFESSION.

To the Editor of The Medical Press and Circular.

Sir,—As your correspondent, "A Surrey Doctor," feels a difficulty about writing to the *Star*, perhaps you will extend to him the courtesy of allowing him to read in your columns the replies to the questions he puts to me.

He asks:—(1) How does the Editor of the *Star* account for the fact that, with the exception of the medical anti-vaccinationists, the whole of the profession take care that their own children are vaccinated? The answer is the familiar one of Dr. Johnson—"Ignorance, sir; sheer ignorance." The exceptions—the medical anti-vaccinationists—are not so "extremely rare" as "A Surrey Doctor" supposes; but they have looked into the question, and have learned so much that they cannot treat their children in the way the rest of the profession treats theirs.

(2) Does the Editor of the *Star* believe that a man, on becoming a doctor, is converted into an anti-human monster, capable of sacrificing his own children in a vile conspiracy for paltry, sordid gain? The answer is "No." Their ignorance sufficiently explains the vaccination of their own children, but will not explain the vaccination of other people's children (by certain

public vaccinators) at ages of from one day to a week in the last quarter before the reduced fees came into operation. Is "A Surrey Doctor" familiar with Emeritus-Professor Crookshank's confessions in his "History and Pathology of Vaccination"? In the preface to this work Mr. Crookshank said his personal investigations had been forced upon him because he "gradually became so deeply impressed with the small amount of knowledge possessed by practitioners concerning cow-pox and other sources of vaccine lymph, and with the conflicting teachings and opinions of leading authorities in both the medical and veterinary professions." At the end of the book stands this perpetual challenge to the profession :—"Unfortunately, a belief in the efficacy of vaccination has been so enforced in the education of the medical practitioner that it is hardly probable that the futility of the practice will be generally acknowledged in our generation, although nothing would redound more to the credit of the profession and give evidence of the advance made in pathology and sanitary science."

(3) Does the Editor of the *Star* not see that if the profession have "those they love" vaccinated, it must be because they, as an army of skilled witnesses, are satisfied that at least vaccination is a perfectly harmless operation? The answer is "No." The "skilled witnesses" appear to be on the other side. What means the doctors may have for ensuring the harmlessness of the operation on their own children he does not know; but the evidence that vaccination is not perfectly harmless to all children is overwhelming; and, as recently as last October, your contemporary the *Hospital* said :—"It is of the very essence of vaccination that it is 'prejudicial to the health of the child.' Everyone knows that it is the intentional transmission of a disease," etc. What wise man will assert that the intentional transmission of a disease can be guaranteed in all cases to be "perfectly harmless"?

But all these questions are irrelevant to the contention of the *Star*. Doctors may hold any opinion they choose about vaccination. The *Star* did not complain of their vaccinating their own children, or the children of consenting parents. It objected to their being empowered to thrust it upon those who deny its efficacy, and to their having a pecuniary interest in this compulsion.

I am, Sir, yours truly,
THE EDITOR OF THE "STAR."

INHERITED SYPHILIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Many phases of the subject handled so nonchalantly in Mr. Clement Lucas's address deserve careful attention. The point raised by your correspondent last week above the signature of "An Average Practitioner," is specially worthy of illumination from many sides. It seems a pity that your correspondent, who is evidently a shrewd observer speaking on the basis of such clinical experience, should not add the authority of his real name. Your correspondent states his experience shows that "a syphilitic father, whether he has been treated or not, seldom, if ever, begets tainted offspring after disappearance of secondary symptoms, say, two years after primary infection, and that after four years the danger is twice as remote." As *treated* cases are dealt with later, we may assume that "Average Practitioner" is speaking of untreated syphilis in the father. His statement, therefore, that such fathers are unlikely to beget unhealthy children is somewhat startling. If this be the case, why is it not recognised by the authorities upon syphilis, who have studied the subject on a basis of accumulated and exact data? So far I can recall no such writer who has laid down any general proposition such as that of your correspondent. That untreated syphilis tends to cure itself is well recognised, but that is a very different thing. It seems to me probable that nowadays very few cases of syphilis escape treatment of some kind, and in many cases the chief aim of the sufferer is to avoid any attention being drawn either to the malady or to its cure. That very fact constitutes a serious fallacy at the outset of any attempt to investigate the proportion of hereditary syphilis found in the offspring of an untreated syphilitic father. The settlement of this point is of importance, and many of your readers must have valuable experiences to relate, could they be induced to come forward. Should "Average Practitioner's" theory be accepted as it stands, it would obviously tend to excuse slackness in the treatment of an essentially curable condition both on the part of the patient and of the practitioner.

I am, Sir, yours truly,
DAVID WALSH.

London, W., January 13th, 1908.

OBITUARY.

JOHN ROBERTS, J.P., M.D.ABER., L.S.A.

CHESTER has suffered a great loss by the death of Dr. John Roberts, J.P., which took place on January 9th. Dr. Roberts, who was 68 years of age, had been in failing health for some time. Educated at Glasgow and Aberdeen, Dr. Roberts had been in practice in Chester for 40 years. He attained a great practice, which extended far over the Welsh border. He was medical officer for more than 30 years to the Victoria Lodge of Oddfellows, which numbers more than 1,000 members. He devoted himself to the study of skin diseases, and gained a more than local reputation in this branch of his beneficent calling. He adopted all the most up-to-date remedies, and electrical and other apparatus for treatment of malignant skin affections, including the Finsen light and Röntgen rays. Some 12 or 14 years ago he started a skin dispensary on the Walls, and there hundreds of afflicted persons received the benefit of his skilled attention free. Dr. Roberts came of Welsh parents, and no more enthusiastic son of Cambria ever lived. Anything of a deserving description associated with Wales, whether political, social, or religious, had in him a zealous, patriotic, and generous supporter. He was one of the oldest members of the Town Council, having been elected so far back as November 22nd, 1886. Three years later he was made Sheriff, and he occupied the position of Mayor with much acceptance to all classes and creeds in 1902, being elected alderman at the expiry of his term of office. He rendered invaluable service to the city as a member of the Public Health Committee, of which for many years he was chairman. He held the position of J.P. for the city since November 4th, 1902, and was very assiduous in the discharge of his magisterial duties. Dr. Roberts was a Liberal in politics, but he was of too kindly and unobtrusive a nature to undertake the more public and controversial side of political life.

SPECIAL ARTICLES.

THE DUBLIN MOTOR SHOW.

NOW that motor-cars are entering so largely into the daily work of medical men, no apologies are necessary for discussion in a medical journal of the different improvements in motor-cars as shown at the great annual shows.

The second annual show promoted by the Irish Automobile Club was opened by the Lord Lieutenant at Ball's Bridge on January 4th, and was continued during the past week. Although to a great extent hampered by bad weather, it has proved a great success, and will do much to add to the ever-increasing body of Irish motorists. Although it may seem invidious to say so, it must be admitted that, to medical men as a class, small cars especially appeal, and therefore it is with them that we are here concerned. The important question to nine out of every ten country practitioners is not whether six cylinders are better than four, but rather whether one or two, or even four, cylinders, with a car attached, can convey their owner about his business in a more satisfactory and rapid manner than, and as economically as, a horse and trap. For this reason every improvement in small cars is of vital importance to the hard-worked medical man.

Now by small cars we mean cars up to 10-12 h.p., and perhaps their makers will excuse us if we arbitrarily divide them into two classes—the cheap small car and the more expensive car. The cheap small car may be said to cost anything up to £250, and the more expensive small car from £250 to £350. Perhaps the most prominent members of the former class which were exhibited in Dublin were the Rover, the Chambers, the Ford, the Reo, the Cadillac, the Starling, the Humber, the Swift, and the Shamrock. Of these cars, the Rover, the Swift, and the Humber are, we fancy, the best known. The Rover Company showed their well-known 6 h.p. and 8 h.p. cars, complete ready for delivery. Both are single-cylinder cars, the smaller costing £130 and the larger £210. The Dublin agency is held by Mr. Willkinson, at 23, Westmorland Street, and the larger model especially has given the greatest satisfaction to medical owners. The Swift 10-12 h.p., at £225, has two cylinders, and so is easier-running. It is remarkable for its well-arranged under-frame, and is a very smart car. The Humbers are referred to by a motor contemporary as being surpassed by none at Ball's Bridge. Two of the smaller models were shown, a 10-12 h.p. Coventry Humber two-seated doctor's car, and a 10-12 h.p. Coventry Rotund. The bodywork of these cars is excellent, and their general character is high, but we should have liked to have had the opportunity of examining a chassis. The price of the Coventry Humber was £250, and it has four cylinders. The Chambers car is an all-Irish car, built in Belfast. It possesses many unusual features, not the least valuable of which is the extreme accessibility of its gears and cylinders. It is specially intended for country owners, who have to keep it in order with a minimum of professional assistance. The 10 h.p. model costs £232. The 10 h.p. Cadillac also possesses several unusual features, one of which is a horizontal engine. It is an American two-cylinder car, and costs £231. The Ford is remarkable for its size and price. It is a four-cylinder 15-18 h.p. car, and costs £175. It is made in the States. The Reo and the Starling are also low-priced cars. Both are single-cylinder, the former as a 10 h.p. costing £175, and the latter as an 8 h.p. £150. The Starling was also shown as a 10 h.p. car costing £200. Altogether the number and variety of cars costing below £250 were considerable.

The list of small cars costing from £250 to £350 was not a long one, and perhaps it is a misnomer to call some of them small. We have done so because their horse-power does not exceed 10-12. The two most important cars of this class were the De Dion and the Siddeley. The former was shown in its celebrated 8 h.p. single cylinder model, costing, with a four-seated body, £273, the latter as a two-cylinder 10 h.p. landaulette. This model, which was beautifully finished, is exceptionally well suited for town work, and should be both economical and reliable. We think it is a pity that makers do not show more of the relatively expensive small cars, as there are many excellent makes on the market. One of the best of these, the 10-12 h.p. Clement-Talbot two-cylinder car at £340, which for reliability and for general excellence of workmanship is unbeaten, was not exhibited. The 10 h.p. De Dion, with two cylinders, at £334, is also a first-class model.

In the gallery round the Main Hall the usual collection of motor accessories was shown. Of these many exhibits, perhaps the most interesting were the new Dunlop detachable wheel; the "Sir Oliver Lodge ignition," a most ingenious arrangement in which Leyden jars are used to increase the intensity of the firing spark; the Rushmore head-lights, the generator for which seems to be a long way ahead of its rivals; the E.I.C. generator for lighting the car lamps; and the H.F. vulcaniser, a piece of apparatus which is almost essential to country motorists.

Space prevents our noticing the many other points of interest in the Show.

Dr. Merling, of Berlin, was performing a serious operation on a child, and fell dead from heart disease. The child unfortunately died in the confusion that followed.

REVIEWS OF BOOKS.

THE HAIR AND ITS DISEASE (*a*).

Dr. Walsh's book on "The Hair and Its Diseases" having survived the wave of infantile mortality which engulfs most medical books, has now attained to the puberty stage of a second edition. Its teaching, therefore, was needed. There are a few outlying quarters of the body which still enjoy almost exclusively the attentions of the quack, this being particularly the case with epiblastic modifications such as the hair and the nails. Considering that medicine cures a great deal *de minimis*, as often significant *de maximis*, it cannot be too strongly insisted by medical practitioners that the claims of the hairdresser to treat the hair, or the manicurist to treat hammer-toe, are either ignorant or fraudulent, or both. This book by Dr. Walsh should do much towards accentuating the difference between skilled and unskilled treatment in affections of the hair, and also in pointing out the dangers as well as the pitfalls of the latter. For the hair, being an integral part of the organism, is affected by general conditions of ill-health, as well as by special local circumstances, and the diagnosis, as well as the treatment, can only be undertaken by a man of all-round knowledge and training. We heartily endorse the expression of opinion on p. 6 that "with hair . . . the best all-round physician is the best man to consult." To such a physician this treatise—brief, handy, and businesslike as it is—should prove most serviceable, for all the points he is likely to desire information about will be found succinctly dealt with under the various headings. Indeed, the strong features of the work, to our mind, are the methods of classification and of clear description, which enable the whole subject to be treated of in less than 100 clearly-printed pages, without necessitating the omission of anything material. We note that Dr. Walsh takes a strong view about the bacterial origin of seborrhœa, and insists correspondingly strongly on antiseptic remedies in its treatment. We consider his plan for the treatment of ringworm—viz., rubbing the shaved scalp over with pure turpentine for three or four minutes, washing with carbolic soap, drying, and painting with tincture of iodine, every night for a fortnight, to be unnecessarily severe for any but extensive and rebellious cases; if it were only intended for such cases the fact should have been stated. On page 23 the author tells us, "Such a pitch of perfection" (*i.e.*, as obtains in surgical disinfection) "is neither necessary nor desirable at the barber's," and lower down on the same page he says, "The main thing to be aimed at by the barber is cleanliness—that is to say, in the surgical and not in the ordinary sense of the word."

But, in spite of one or two minor inconsistencies, we feel sure that Dr. Walsh's book will prove exceedingly useful to those practitioners who have hitherto given but little attention to the subject, or have devoted too much attention of the wrong kind.

NAUHEIM TREATMENT OF CARDIAC AFFECTIONS (*a*).

Nauheim, thanks to the ingenuity and enterprise of the Brothers Schott, has won world-wide renown as a centre for the treatment of chronic cardiac disease. Dr. Thorne-Thorne has done well to make known to British practitioners the means whereby the "Schott" exercises and the "Nauheim" baths can be advantageously employed in this country. The fact that his *brochure* has passed into its second edition is evidence that his work has been appreciated. In the present issue the action and administration of both exercises and baths are explicitly detailed, and directions are given for the judicious selection of cases. Clinical particulars are given of patients who have benefited. The chief feature and special value of the manual will be

found in the excellent series of 28 photographs illustrating the various exercises employed in carrying out the "Schott" exercises. The work will be of practical assistance to many practitioners.

INDEX OF TREATMENT (*a*).

LIVING, as we do, in a tabloid age, indices, ready-reference lists, and dextrinised literary gruel are a necessity of existence, and it is a tribute to the ingenuity of medical authors that they find so many different media through which to supply the needs of their brethren. For ourselves, we confess to a leaning towards the old type of book produced by one master-mind, but it is a fact which must be faced that only a Napoleon of medicine could write single-handed a full, first-hand treatise on the whole medical, surgical, and gynæcological treatment such as that which lies before us. The editors, Dr. Robert Hutchinson and Mr. Stansfield Collier, have secured a good serviceable staff of coadjutors, many of them well-known writers on the subjects they set forth; others—a good proportion—belonging to the younger generation. It is noticeable also that the choice has been pretty catholic, and at a glance there seem to be almost as many contributions from the North as from the South of the Tweed. It was certainly ambitious to hope to compress into 850 pages the whole of treatment, even when, as is here the case, only the proceedings found most successful by each writer are given; but the attempt has proved a success. Everything, except operative details and the management of labour, have been given, and the space allotted is generally sufficient for a fairly adequate presentation of each subject. Naturally, the articles vary much in merit, but the general level is certainly high. It is admittedly difficult to avoid padding, as it is necessary to do in a somewhat condensed work such as this, and yet to be explicit. It thus often happens in the shorter articles that the writers are obliged to lay down a number of cut-and-dried dogmatic rules which can only apply in practice to a certain proportion of cases, but even in some of these articles there is found a good deal of redundance in non-essentials, side by side with parsimony in essentials, and we cannot say that the only offenders are the less practised writers. But, taken as a whole, we think the work a very valuable one, and we have no doubt it will be popular, for it will fill a particular niche which we do not remember to have had an occupant before. It is comprehensive, handy, and accurate; the alphabetical arrangement of subjects and the index at the end make reference easy; and the size and get-up are conducive to pleasant handling. We congratulate both editors and contributors upon having added to medical literature a useful and comprehensive work, which will take its place among the more lasting and solid additions to medical literature.

MEDICAL ETHICS (*b*).

THE man-in-the-street counts matters of "medical etiquette" as "past finding out," and, in spite of the golden rule to direct life's procedure, the fact that Professor Saundby's admirable little "guide" has reached a second edition goes far to demonstrate that even in the realm of medical ethics, exposition, by precept and example, is not uncalled for, and may at least satisfy curiosity, if even it does not direct or rectify conduct. Dr. Saundby has entered where angels might fear to tread, but he has trod the thorny and treacherous path with discerning care and discriminating judgment, and although there are points on which doubtless many will differ from him, and although some may consider his work not altogether guiltless of certain errors of commission rather than blamable from sins of omission, yet the best opinion will, we venture to think, attest that the work is marked by a sound sense of justice, clear knowledge of both the needs and the difficulties of medical practice, and a sympathy with the practitioner as well as a high ideal for the profession of medicine. The work is, as far as we know, unique, and although, of course, written as a personal expression of opinion, is likely to attain an authoritative position as formulating a more or less definite code governing professional opinion and action in the numerous intricate and perplexing problems, from some of which, at least, no practitioner of the healing art can expect to escape. Dr. Saundby's work is one which should be within reach of every practitioner, and will be of particular value and service to those recently qualified.

HYGIENE AND PUBLIC HEALTH (*a*).

SLIGHTLY changed in shape but approximately the same in bulk this, the third edition of Dr. Parke's standard work, has been carefully revised and brought up-to-date. Students of State medicine have indeed much to be thankful for. When the diploma in public health was established the only available work was the Parke-Chaumont treatise on military hygiene, and this, though a splendid achievement in view of the then undeveloped science of public health, left much to be laboriously gleaned from Government reports, Blue Books, and similar publications in which the information had to be perseveringly winnowed. Now, thanks to extended experience and improved statistical methods, the subject has been boiled down and brought within manageable compass. A work of this sort obviously does not exhaust the subject. The student will find it necessary to supplement the information therein contained in many points, but this is inherent to the comprehensive and often highly technical nature of the subject which moreover comprises matter only to be learned from practical work, within and without the laboratory. The work is liberally illustrated and beautifully printed on opaque (non-glossy) paper. It is certain to maintain its popularity with students and practitioners.

INTERNATIONAL CLINICS (*b*).

THE present volume of this well-known quarterly contains a number of practical clinical papers dealing with a variety of subjects, most of which are of interest to the practising physician and surgeon. In the section devoted to gynæcology the first paper deals with the use of collargol in puerperal injections. The writer reviews the history of the use of the drug in septic conditions, and after enumerating the different methods of application describes his own technic of intravenous administration. He prefers to make use of a 1 per cent. solution, injecting about 10 c.c. as a dose, and claims to have had remarkable success. As, however, no account of his cases is given it is impossible to form any independent judgment as to the success he has achieved. The second paper in the same section is on the subject of "Atopomenorrhœa," or vicarious menstruation. The writers have reviewed the literature dealing with the subject, and after eliminating doubtful cases, show that there is sufficient evidence to contravert Bland Sutton's dictum that the existence of such a condition is merely an exploded superstition. The ophthalmological section contains an important paper by Thomson and Buchanan on "Ocular Birth Injury," which is well worthy of perusal, while another short paper on the simple subject of how to turn back the upper eyelid will be read with profit by many. To the surgical section Dr. Saret contributes an article on "The Surgery of the Blood Vessels"; Dr. Loeb one on "The Inoculability of Tumours and the Endemic Occurrence of Cancer"; and Dr. Vaughan a paper on "Inflammation of the Gall Bladder and Gall Ducts." The sections on therapeutics, medicine, and genito-urinary diseases also contain several interesting papers, which space forbids us to enumerate in detail.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

Hyperæmia in the Treatment of Tuberculosis of the Peritoneum.—Hertzler (*Surg. Gynæcol. and Obstetrics*, December, 1907).—As a result of a series of experiments conducted on mice, rats, and guinea-pigs, the writer makes the following statements: (1) The result of opening the abdomen is a hyperæmia of the peritoneum and sub-peritoneal tissues, due to the lessening of pressure from without. (2) Hyperæmia has been found of use in tuberculosis elsewhere, and by analogy we may be warranted in assuming the same factor as active in the treatment of tuberculosis in the peritoneum. With these two facts in mind it seems that this is the factor underlying improvement by opening the abdomen in some forms of peritoneal tuberculosis. This assumption finds a clinical support in the fact that it is only the type with exudation that is so benefited. This is easily explained on this theory, for manifestly in the hyperplastic types the vessels cannot dilate to any considerable extent, therefore the operation can be of no use. If this view be correct, the benefit obtained from a single treatment would be much enhanced by a repetition of it. This can be obtained by leaving a silver tube with a flange within the peritoneal cavity, so that air may be admitted into the abdominal cavity at intervals. By this means repeated engorgements can be obtained, just as in the case of treatment of joints, without the danger or inconvenience of repeated laparotomies.

F.

Treatment of Mastitis with Breast Suction.—Zachorios (*Amer. Jour. Obst.*, October, 1907).—The author believes that at the beginning of a case of mastitis this treatment is a sovereign remedy. Only failure of the technique, or beginning the treatment too late, will give unsatisfactory results. In cases, after abscess formation has taken place, no benefit will be received. The method enables the mother to continue nursing her child, while under the old system it was necessary to stop nursing, and on recovery the milk was gone from the breast. Under this treatment lactation is rather a benefit to the mother. The best method of applying the treatment is to begin as soon as there is any rise of temperature, and give three suctions daily of half an hour each. After the temperature has fallen and inflammation disappeared suction is stopped, treatment being needed for two or three days at most. When by the third day the temperature has not fallen to normal we may expect abscess formation. The bell glasses should be large enough to entirely cover the gland, and should not give any pain. In thin patients a little air may get under the bell, and this will give pain, so that some pressure may be needed to keep the bell in contact with the thorax. The bell must be filled gradually with air at the end of the treatment. The treatment should never be put into the patient's own hand to execute.

F.

Deferred Operation for Ruptured Ectopic Gestation.—Simpson (*Surg. Gynæcol. and Obst.*, November, 1907) considers that the teaching of immediate operative interference—no matter how collapsed the patient may be—is most unfortunate, and says facts do not warrant such conclusions. If a woman with a ruptured tubal gestation is sure to bleed to death then an operation is called for at once, but the writer maintains that only a small percentage of ruptured ectopic gestations end in this way. He quotes authorities to show that primary hæmorrhage from the stomach, intestines, lungs, or uterus may be severe, but rarely proves fatal, and he maintains that the same holds good when the hæmorrhage is from a ruptured ectopic gestation. He considers that operation should be at an elective period and under favourable conditions. The elective periods are before rupture, or if rupture has occurred, within as short a time as the most favourable conditions demanded for other elective operations, can be had. The time may be at once when there is little depression, or at any time within several weeks if there has been great collapse. The expectant treatment he adopts is absolute rest in one position without any voluntary movements, and avoidance of examination. He gives small doses of morphia to ensure rest, and gradually increases the fluid in the blood vessels by repeated injections of normal saline solution into a vein. Small doses of adrenalin chloride are given with the injections, and strychnine, camphor and digitalis are administered.

F.

Report of a Case of Ovarian Cyst with Twisted Pedicle, Complicating Pregnancy and Labour (*Surgery, Gynæcology, and Obstetrics*, December, 1907).—Edward P. Davis describes a case of this nature which came under his care in the Jefferson Maternity. The patient, æt. 32, was in her third pregnancy. Her first confinement had been terminated by forceps, the child dying soon after birth. The second pregnancy likewise necessitated forceps to complete delivery, the child succumbing to birth pressure. Becoming pregnant for the third time the patient and her husband expressed a great desire to have a living child, and written permission was obtained to deliver the patient by any method which seemed most likely to save her life and that of her child. The pelvic measurements were as follows:—Inter-spinous, 26.5 cms.; inter-coxal, 27 cms.; inter-trochanteric, 30 cms.; right diagonal, 22 cms.; left diagonal, 21 cms.; external conjugate, 18 cms.; circumference, 82 cms. On examination, the abdomen was found abnormal in contour, the back of the child towards the left, the head not fixed, and a distinct fullness upon the right side. What this was could not be made out, the patient being in labour and the contractions good. The head was found to lie transversely at the brim and not engaged, by vaginal examination. It was decided to perform cœliohysterotomy. On opening the abdomen difficulty was experienced in turning out the uterus, but eventually this was done, and a tumour, which proved to be the right ovary having undergone cystic degeneration, turned out also. The uterus was opened, and a 5lb. 15oz. child extracted alive and vigorous. The uterus was then closed, and the cystic right ovary was clamped off and removed—it was as large as a full term fœtal head. The pedicle was found to be twisted on itself three times from right to left. It was very congested, but not gangrenous. The abdomen was closed without drainage, and the mother and child made an uncomplicated recovery. Dr. Davis points out the following points: The tendency for ovarian cysts to twist their pedicle during pregnancy, for which there seems no adequate explanation. That efforts at a delivery by the vagina are most dangerous, as manipulation most frequently bursts the tumour, giving rise to peritonitis and death. He considers the patient owes her life to the method of delivery, and that wherever it is possible to diagnose the presence of an abdominal or pelvic tumour complicating pregnancy, delivery by abdominal section is the safest procedure. Furthermore, that unless there is distinct evidence of pus or gangrene, the abdomen should be closed without drainage.

H.

Removal of the Placenta.—Hofmeier (*Berliner Klin., Wochensch*, 1907, Nr. 12) agrees with Ahlfeld that the placental stage should be treated altogether expectantly. If there should be hæmorrhage, the first thing to try is expression by Credé's method. In order to measure the amount of blood which is being lost, a clean vessel should be put under the woman immediately after the child has been delivered. If the amount of blood lost exceeds one litre, and attempts at expression even under an anæsthetic fail, the placenta should be manually removed. Before this is done the vagina should be thoroughly soaped, and washed out with lysol or lysoform. The hand of the operator should be covered with a sterile rubber glove. The separation of the placenta is sometimes rendered very difficult by dense adhesions between it and the uterine wall. The author regards this as being due either to a complete atrophy of the decidua basalis or to the deep insertion of the chorionic villi into the uterine wall. It may be difficult to recognise whether the placenta is complete, not only in those cases where dense adhesions have been present, but also when the separation has been very easy, or even when the third stage has apparently been quite normal. If one is uncertain, the uterus should be again examined when the patient is bleeding or when one cannot hope to have the patient under constant observation during the lying-in period. Hofmeier regards the retention of chorion, even of the entire chorion itself, as an occurrence of not very great importance. In such cases he only recommends plenty of ergot, and douching of the vagina occasionally with a weak antiseptic solution. If the physiological signs of separation do not occur, but there is no appearance of hæmorrhage, it is the author's opinion that there is nothing to be gained by putting off the manual removal of the placenta for longer than three to four hours. G.

Spontaneous Intra-Uterine Rupture of the Umbilical Cord due to its Abnormal Shortness.—Walther (*Gynäkol, Rundschau*, 1907, Nr. 10) records the case as follows:—The patient, a primipara, æt. 28 years, complained during her pregnancy of very severe cramps and dragging pains in the abdomen. The labour pains began six weeks before full term, and although they continued for more than two days they did not complete the delivery. It was a case of twins, the brow of the first presented, and this child was delivered in good condition with forceps. There was a good deal of hæmorrhage, which was checked by gentle massage of the uterus. The second bag of membranes ruptured very soon, and the breech of the child appeared. This second child was born very easily without any assistance whatever being given to the mother. The child was alive, and the fact was revealed that the cord had been torn apart about 3 cm. from the umbilicus. The child had a spina bifida, atresia ani et urethræ, an an umbilical hernia. There was no hæmorrhage from the torn cord. The child died after a few hours. There were two separate placentæ with a common chorion. The cord of the first child had a velamentous insertion, and was intact. The cord of the second was inserted into the margin of the placenta, and measured 9 cm. from its insertion to where it was torn. Macroscopically it was quite normal in every other way. Walther believes that the pains during pregnancy were due to the shortness of the cord, and that many cases of so-called rheumatism of the uterus could perhaps be explained in this way. G.

Elisa Dehring, 50, who pleaded guilty last sessions at the Old Bailey to a conspiracy with others that a person should commit an illegal operation on Elsie Herget, came up for sentence on January 8th. Sir Charles Mathews said the parties were Germans, and in June last Herget went to stay with the prisoner, who was a cook in Crediton Street, Hampstead. He explained the steps taken by the prisoner with regard to the illegal operation, and said Herget died from the effects in St. Mary's Hospital. Mr. Gathorne Hardy, for the prisoner, said she had been in custody three months, and Mr. Justice Bigham passed the nominal sentence of two day's imprisonment, so that the prisoner was at once discharged.

Medical News in Brief.

Preservatives in Tinned Foods.

At Bow Street, on January 8th, before Mr. Marsham, Joseph Launay, a provision merchant, of Charing Cross-road, was summoned for selling a 1lb. tin of peeled shrimps containing 43 grains of boric acid. Mr. Rotton supported the summons on behalf of the Westminster City Council; Mr. D. Nimmo defended. Dr. Allan, medical officer of health for Westminster, gave evidence that the amount of boric acid alleged in the summons was sufficient to set up indigestion, and would act as an irritant on the kidneys. For the defence, Dr. W. Griffith stated that if the shrimps were washed when they were taken out of the tin, as was usually done, it would be found that they had absorbed only 1 or 2 per cent., and possibly none at all, of the boric acid. He was of opinion that no ill-effects would result from a person eating half a pound of shrimps containing the percentage of boric acid in question. Mr. Felix C. Kempster, Divisional Surgeon of Police for Battersea, was also called for the defence. He said that he had never traced indigestion to boric acid. A quarter of a pound of tinned shrimps would be a large quantity to take at one meal, and that amount, if it contained the percentage of boric acid alleged in the summons, would not be injurious to health. The defendant said that tinned shrimps were generally used for making sauce, and 2 oz. would flavour sufficient sauce for 50 people. He had since returned his whole stock of tinned shrimps to the firm which supplied him with them. The magistrate said that there was no reason why a person should not consume the whole of the contents of the tin if he felt so disposed, and in that event the amount of boric acid would undoubtedly be injurious to health. He fined the defendant 40s., and ordered him to pay £3 3s. costs. Mr. Nimmo intimated that there would possibly be an appeal.

Assault on a Medical Man.

On January 8th, Henrietta Fitzgerald, 30, a machinist, was indicted for wounding Dr. Ernest Cranmer Hughes with intent to do him some grievous bodily harm. She pleaded "Guilty."

Mr. Justice Bigham (to the prisoner): You plead guilty?

The Prisoner: Yes. It is not right for me to have to fight this case. I cannot get any sleep at Holloway. There is a kitchen over my head, and I cannot get to sleep until 2 in the morning.

Mr. Justice Bigham: You plead guilty to this offence?

The Prisoner: Yes. I had jolly good reason to do him grievous bodily harm.

Dr. Griffiths, Medical Officer of Holloway Prison, said the prisoner had been in Holloway upon the charge since November 22nd, and during most of that time she had been under his observation. As a result of that observation he had formed the opinion that she was insane.

The Prisoner: I am not given a fair chance.

Dr. Griffiths, asked his reasons for that opinion, said she was mentally unstable and had delusions. He had seen some letters written by her which were full of extraordinary statements.

Dr. Griffiths further said the prisoner had threatened what she would do to Dr. Hughes when she came out. Some Easton's Syrup was given to the prisoner at Holloway.

Mr. Curtis Bennett, who appeared for the prosecution, said the prosecutor, Dr. Hughes, was assistant surgeon at the Lock Hospital. The prisoner was a patient there, and she alleged that the doctor had injured her by using a speculum. She met Dr. Hughes outside the hospital and struck him with a hammer. For a time he was in a dangerous condition as a result of the blow.

The prisoner was continuing her remarks, but the learned Judge said he could not listen to her any further.

Mr. Justice Bigham said he was satisfied that she was in a very bad state of health mentally and probably also physically. He should do the best he could for her, and he should send her to prison for twelve months. There she would be properly treated, and he hoped that at the end of that time she would be restored to health.

The Prisoner: You are not going to send me to a lunatic asylum?

Mr. Justice Bigham: No, certainly not. Unless you behave in such a way as to make it necessary to put you into a lunatic asylum you will not be.

The Prisoner: Will you have me removed from Holloway? It is absolute tyranny there.

Mr. Justice Bigham: I am afraid I cannot do that.

The prisoner was then removed.

Mr. Justice Bigham said there was not the slightest reflection on Dr. Hughes.

Brown Dog Meeting at Battersea

A "preliminary mass meeting " was held at Battersea Town Hall, January 10th, to protest against the suggested removal of the Brown Dog anti-vivisection memorial at Battersea. Apart from the large body of stewards there was only a moderate attendance, the lavish display of posters headed "Shall Battersea Lose Its Brown Dog?" having evidently failed to rouse local enthusiasm. Mr. Ewell McAllen presided, and the Mayor of Battersea (Mr. Worthy), with several borough councillors and local Socialist leaders, was on the platform.

The Chairman said the meeting was called by the London and Provincial Anti-Vivisection Association, first, to protest against the iniquitous system of vivisection, and, secondly, to try and instil a little courage into those who were in control of the forces of law and order. He extended a somewhat qualified welcome to the medical students who, he understood, were present. When medical students demonstrated in Trafalgar Square on behalf of the underfed children or against the wretched conditions under which the masses lived they would agree with them. Having referred to the letter of the Commissioner of Police suggesting that the memorial should be removed or that the Battersea Borough Council should pay the £700 a year spent in guarding it, the chairman asserted that it was not due so much to a desire to economize as to certain influences which were at work.

Mr. Willis moved:—"That this meeting condemns the practice of vivisection as being inseparable from cruelty to its dumb victims, and as dishonouring to the nation which encourages and supports it." This, he said, was a declaration against cruelty in every shape or form, and he asked the meeting to pass it unanimously. He read the inscription on the memorial, and maintained that it was true and its continuance was needed as a protest and a reminder.

Mr. Wall, physician and surgeon, of the Battersea Anti-Vivisection Hospital, seconded the resolution, and said a miserable minority of vivisectors dominated the whole medical profession. It was an insult to common sense to assert that experiments on living animals were conducted without the infliction of pain.

Mr. Sidney Trist protested against honours being bestowed on those who had built up a reputation on the sufferings of animals.

There was some cheering when Mr. D. Carmichael, a Socialist, said bludgeons would have been used if the unemployed instead of medical students had attacked the memorial. If the students chose Battersea as a battle ground they would have a warm welcome.

The resolution was carried.

Gift of a Sanatorium.

A munificent gift of a sanatorium, fully endowed, has been made to Bolton, Lancashire, the donor being Mr. Thomas Wilkinson, one of the oldest residents in the town. Owing to the trying industrial conditions, which make consumption exceedingly rife, a sanatorium had become an urgent necessity, but the corporation and other local bodies had hitherto been at a loss to find the means for providing one.

Mr. Wilkinson has set apart for the purpose his large residence on the outskirts of Bolton, standing amidst spacious grounds, with terraces, lawns, and gardens, all of which render it a most desirable place. Its altitude is 700ft.

The donor has had a remarkable career. Starting in very humble circumstances, he developed an important cotton business, and during the American war amassed great wealth in blockade-running.

Protest Against Notification of Births Act at Exeter.

At the meeting of Exeter City Council, on January 8th, the Mayor (Ald. Gadd) presiding, the Town Clerk read a communication from the Local Government Board consenting to the adoption of the Notification of Births Act, 1907, within the city, and fixing January 13th, 1908, as the date on which the Council's resolution of adoption of the Act should come into operation.

A deputation of medical men of the city, consisting of Dr. Davy, Dr. Gordon, Dr. Ransom Pickard, Messrs. Russell Coombe, E. J. Domville, J. Miller and M. Farrant, attended on this subject.

Dr. Davy said medical men disliked the Act extremely, because it violated one of the cardinal principles of the profession, that of preserving secrecy. Up to the present the medical profession had always treated what a patient told them as an absolute secret —a trust which they could not violate by disclosing it to other people. (Hear, hear.) The Act stated that they were to break through this professional secrecy, which they considered one of their most honourable traditions, in all cases in regard to births. Of course, in the case of married women it was a matter of indifference whether or not a birth was notified; but there were constantly cases of illegitimate births, which they knew the endeavour was to keep secret. Medical men objected, as a profession, to have it forced upon them to violate the secrecy which these unfortunate people were bound to confide in their medical man. Of course, the medical profession recognised there was an enormous amount of infanticide which could be prevented, and a large number of deaths among children which could also be prevented. As a profession, they were willing to do everything possible to assist the Legislature and County Councils in aiding towards this desirable result. But in any case it was possible to do it with something like decency.

Mr. E. J. Domville endorsed what Dr. Davy had said relative to the importance of maintaining professional secrecy. Without in any way reflecting on the work of the office of the Sanitary Inspector, there would be a great danger against keeping these things confidential if the notices were sent in the same way as Infectious Disease Notification notices, and were allowed to lie about an office which was used by a large number of people.

Dr. Gordon said the medical profession was quite as anxious as any lay body that the spirit of the Act should be entirely carried out. They did not object to the Act in its intention, but they objected to one part of the Act, that which dealt with the medical profession.

Dr. Ransom Pickard, who also spoke, contended that the secrecy observed by the profession was in the public interest.

The Mayor thanked the deputation, and promised that the matter should have the careful consideration of the Council.

Grant in Aid of Scientific Research.

We are asked to announce that the Odontological Section of the Royal Society of Medicine is prepared to receive applications for grants in aid of the furtherance of scientific research in connection with dentistry. For particulars and forms of application apply to the Hon. Secretary, Scientific Research Committee, Odontological Section, Royal Society of Medicine, 20, Hanover Square, London, W.

Apothecaries Hall of Ireland.

At a special examination held on the 3rd inst., Edward Magennis, M.D., D.P.H., was admitted a licentiate of the Apothecaries' Hall.

NOTICES TO CORRESPONDENTS, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Opsonin.—The correct way to pronounce the word, of course, is opsō-nin, for it is derived from ὀψωνειν (to cater for). In practice, however, the genius of the language has already asserted itself, and opson in is generally used. In a few years any opsō-ninists who survive will be regarded with the same astonishment as we should regard an antisē-ptic pronouncer. In such cases there is no rule except to say the most convenient thing.

Mus.—The number of rat-destroyers grows daily, and we cannot pretend to pronounce on their respective merits. Several of them have very good credentials from experience in temperate climates.

Kind.—The usual rule of calculating doses for children by multiplying the adult dose by the child's age over its age + 12 is a very rough one, and we do not know the genius who invented it. At any rate, his name is blessed to every examinee in prescription-writing. But, beyond the peculiar sensibility of children to certain drugs, such as opium, it seems to be a fact that they are at times more highly susceptible to all drugs than at others. Whether this is related to any opsonic index or not we do not know, but it is certain that at periods of rapid growth, *e.g.*, in convalescence, the susceptibility is more marked than at ordinary times. Troitzki has worked the question out in young animals, guinea-pigs, dogs, and rats, using strychnine, atropine, and pilocarpine, and is of opinion there are certain periods of active growth when sensibility to drugs high in all young animals.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 15TH.

Royal Microscopical Society (20 Hanover Square, W.).—8 p.m.: Mr. W. Wesche: On the Microscope as an Aid to the Study of the Biology of Insects, with Special Reference to the Food. Mr. J. C. Barnard: Exhibition and Description of an Improved Type of Mercury Vapour Lamp for Use with the Microscope.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. P. Daniel: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. C. Mercier: Functional Disease and its Treatment.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Cliniques: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

THURSDAY, JANUARY 16TH.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Sir Almroth Wright: Some Points in connexion with Therapeutic Inoculation.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Lecture Demonstration: Dr. G. N. Meachen: Selected Skin Cases.

Hospital for Sick Children (Great Ormond Street, W.C.).—4 p.m.: Lecture:—Mr. W. W. James: Importance of the Care of the Teeth in Childhood.

St. John's Hospital for Diseases of the Skin (Leicester Square, W.C.).—6 p.m.: Lecture:—Dr. M. Dockrell· Bullous and Vesicular Eruptions: V., Herpes; VI., Zoster; VII., Dermatitis Herpetiformis.

FRIDAY, JANUARY 17TH.

Society of Tropical Medicine and Hygiene (20, Hanover Square, W.).—8.30 p.m.: Dr. G. C. Low: The Unequal Distribution of Filariasis in the Tropics. Dr. C. Brown: Biographical Sketch of the late Professor Fritz Schaudinn.

Society for the Study of Disease in Children (11, Chandos Street, Cavendish Square, W.).—4.30 p.m.: Dr. G. Carpenter: Successful Medical Treatment of Congenital Hypertrophic Obstruction of the Pylorus. Dr. E. Cautley: Pathology of Congenital Hypertrophy of the Pylorus in Relation to Treatment. Dr. Whipham, Dr. P. Parkinson, Dr. Carpenter, and others: Cases.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. B. Harman: Clinique. (Eye.)

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques: Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. M. Leslie).

Great Northern Central Hospital (Holloway Road, N.).—Lecture:—Dr. C. H. Wilcox: Exophthalmic Goitre.

Appointments.

Badcock, E. R., M.R.C.S., L.R.C.P.Lond., Surgeon to the General Post Office, Wandsworth Sub-district.

Bergin, Frank Gower, L.R.C.P.Lond., M.R.C.S., Medical Officer to the Bristol Dispensary.

Gayner, J. S., L.R.C.P.Lond., M.R.C.S., Anæsthetist to the York County Hospital.

Gray, A. Montague H., M.D., B.S.Lond., M.R.C.P.Lond., Obstetric Registrar to University College Hospital.

Gregor, Alexander, M.D., C.M.Aberd., Medical Officer of Health of Falmouth.

Jewesbury, Reginald C., M.A., M.B., B.Ch.Oxon., M.R.C.P. Lond., Physician to Out-patients at the Victoria Hospital for Children, Chelsea.

McDonald, Gilbert Reginald, L.R.C.P., L.R.C.S., L.M.Irel., District Medical Officer by the Tiverton (Devon) Board of Guardians.

Nobbs, Athelstane, M.D.Edin., Surgeon to the General Post Office, Putney Sub-district.

Price, Florence, M.B., B.S.Edin., to the Bacteriological Department at Swansea Hospital.

Thomas, H. Darby, M.R.C.S., L.R.C.P.Lond., Assistant House Surgeon at the Royal Surrey County Hospital, Guildford.

Vise, John Neville Blithe, M.R.C.S., L.R.C.P.Lond., Medical Officer of Health of Chard (Somerset).

Walker, George Francis Clegg, M.B., Ch.B.Vict., Medical Officer of Health for the Haverfordwest (Pembrokeshire) Rural District.

Vacancies.

Joint Counties Lunatic Asylum, Carmarthen.—Assistant Medical Officer. Salary, £200 per annum, with board, lodging, washing, and attendance. Applications to W. Morgan Griffiths (Solicitor), Clerk to the Visitors, Carmarthen.

Somerset County Council.—The County Education Committee.—Chief Medical Inspector of Schools. Salary, £500 per annum, with out-of-pocket expenses. Applications to the County Education Secretary, Weston-super-Mare.

Kent County Asylum, Maidstone.—Fourth Assistant Medical Officer. Salary, £175 per annum, with furnished quarters, attendance, coals, gas, garden produce, milk, and washing. Applications to the Medical Superintendent.

Berry Wood Asylum, Northampton.—Junior Assistant Medical Officer. Salary, £150 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent.

Great Northern Central Hospital.—Pathologist and Curator. Salary, £100 per annum. Applications to L. H. Glenton-Kerr, Secretary.

National Maternity Hospital, Dublin.—Indoor Assistant Physician.—Salary, £50 per annum.—Applications to the Secretary.

Births.

Burtchaell.—On Jan. 8th, at 23, Palmerston Road, Dublin, the wife of Lieut.-Colonel C. H. Burtchaell, R.A.M.C., of a daughter.

Lock.—On Jan. 7th, at 12, Huntingdon Road, Cambridge, the wife of Lyonel J. Lock, M.R.C.S., L.R.C.P., of a daughter.

Mennell.—On Jan. 10th, at 57, Holland Park Avenue, London, the wife of Zeb. Mennell, M.B., of a daughter.

White.—On Jan. 8th, at the Dower House, Bugbrooke, Northamptonshire, the wife of Percy Stanhope White, M.R.C.S. and L.R.C.P.Lond., of a daughter.

Marriages.

Fothergill—Gell.—On Jan. 8th, at St. Andrew's, Kingsbury, Claude Francis Fothergill, B.A., M.B., B.C., fifth son of Thomas Rowland Fothergill, to Enid Annesley, younger daughter of the late Major-General John Sherbrooke Gell.

Roderick—Clay.—On Jan. 9th, at Great St. Mary's Church, Cambridge, Henry Buckley Roderick, M.D., son of the late William Roderick, to Hilda Mary, daughter of John Clay, of Burrell's Corner, Cambridge.

Deaths.

Boyce.—On Jan. 3rd, at Fir Grove, Simla, India, Florence, wife of Charles Boyce, M.D., late of Maidstone, Kent.

MacLaurin.—On Jan. 7th, at 155, Macquarie Street, Sydney, N.S.W., Eliza Anne, wife of Sir Normand MacLaurin, M.D., and daughter of the late Dr. Charles Nathan.

Scott.—On Jan. 10th, at High House, Old Charlton, Patrick Cumin Scott, B.A., M.B.Cantab., youngest son of the late James Nairne Scott, of Blackheath, in his 51st year.

Darwent.—On Jan. 6, at Port of Spain, Trinidad, of yellow fever Stella Cecilia, the beloved wife of Dr. Darwent, and youngest daughter of the late Thomas Parker Rust, M.R.C.S., L.S.A., of Wells-next-Sea, Norfolk.

Peptogenic Milk Powder

Cows' milk prepared with PEPTOGENIC MILK POWDER becomes remarkably like mothers' milk in all particulars: in physical properties, in colour and taste, and in the percentage of nutritive constituents: in its digestibility, its behaviour with acid, with rennet, and in the infant's stomach.

Milk prepared with the PEPTOGENIC POWDER has simply the normal digestibility of mothers' milk: is not too easily or unnaturally digestible, and contains no aid to digestion. It affords a complete substitute for mothers' milk during the entire nursing period.

Supplied to the Medical Profession in two sizes, at 1/10 and 3/8 each.

'Pepsencia'

PEPSENCIA is an ever-ready digestive fluid possessing remarkable peptic and rennet activity. It contains pure pepsin, the vitality of which is unimpaired by chemical action or manipulation, and it is obtained by direct solution from the secreting glands of the gastric mucous membrane, every care being exercised to preserve its full physiological activity.

The usual dose is a teaspoonful before or after meals in all cases where pepsin is indicated.

Supplied to the Medical Profession in 4 oz. and 8 oz. bottles, at 1/10 and 3/3 each.

'Panopepton'

PANOPEPTON presents the entire substance of prime lean beef and best wheat flour in a perfectly soluble, diffusible, and absorbable form. It is at once a grateful stimulant and food.

For an adult, the usual portion should be a dessertspoonful to a tablespoonful several times a day and at bedtime.

Supplied to the Medical Profession in 6 oz. and 12 oz. bottles, at 2/2 and 3/8 each.

Specimens and literature will be forwarded on request.

"2me VIN," fully branded, beautiful bouquet, a shade lighter than the "Grand Vin" .. ..

Price for the Continent and for Export fr.2.50 per bottle free on rail or export ship "Bordeaux"

Thus the Premier Claret (the Chateau Lafite) of a class **usually sold at about 84/0** per dozen **is now offered by us at less than 2/6 per bottle.**

An allowance of
6d. per doz. on from 12 doz. to 29 doz., and
1/0 " " 30 doz. and upwards will be made.

Never before was such an opportunity offered to Connoisseurs to acquire a Wine of this famous growth and of such quality and with complete guarantee as to authenticity at so low a price. Admirers of fine Claret should not miss this opportunity, which is not likely to occur again.

The Barons de Rothschild, the Proprietors of the famous Chateau Lafite, did not, during the greater part of the 'eighties, permit any bottling at the Chateau; but the superior 1890 Vintage was bottled for them with full brand on corks, and held in a special cellar, small quantities only having been parted with.

The Wine was bottled in greatest perfection, is in splendid condition, showing its great breed and style, possessing fine colour, beautiful bouquet, great elegance, and matured fruitiness. It is very soft and mellow, and a most superior dinner and dessert Claret of best style.

In sympathy with the movement to assist the undoubted revival in taste for high-class Claret, the holders have been prevailed upon to sell, and **we have purchased the whole existing quantity** of this excellent Wine at a most reasonable price and have been placed in a position to offer it at the above nominal and most moderate rates, far below its true value and less than half the usual selling price of this growth and quality.

Quantity required. M.P. **ORDER FORM** Per doz. £ s. d.

HOME WINTER HEALTH RESORT.

Royal Hotel and Baths, Matlock Bath.

Every Bath Obtainable on the Continent can be taken here without the expense and fatigue of travelling abroad. **Under Medical Direction and Supervision.**

BATHS & HYDROTHERAPEUTIC TREATMENT.

All Baths are in the Hotel and are accessible by Electric Lift. (The possibility of taking chills" is avoided, patients ascending from the baths to their rooms without going outside).

Russian, Turkish, Nauheim, Vichy, Aix, Electric Light, Brine, Sulphur, and Pine Baths, Spray, Needle, Sitz, and Douche Baths.

MASSAGE. A competent staff of masseurs and masseuses, trained to give ordinary Swedish, and electric massage.

ELECTRIC TREATMENT. High Frequency, Radiant Heat, Four-cell, Static, Faradic and Galvanic, and "X" Rays.

DOWSING RADIANT HEAT BATHS.

FANGO DI BATTAGLIA (Volcanic Mud). Most effective for the local treatment of Gout, Rheumatism, Sciatica, Neuritis, &c. Extensively used abroad at all the chief bathing places, Fango di Battaglia is now available at Matlock Bath.

WEIR MITCHELL TREATMENT.

RESIDENT NURSES AND ATTENDANTS.

For Special Winter Terms apply to the manager, Royal Hotel, Matlock Bath, who will send illustrated prospectus free.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXVI. WEDNESDAY, JAN. 22, 1908. No. 4.

NOTES AND COMMENTS.

The L.G.B. Medical Officership.

THE retirement of Mr. W. H. Power from the post of Medical Officer to the Local Government Board will be a matter of sincere regret to all medical men. Mr. Power has always seemed to us a model of what a man holding that position should be. In scientific eminence, in practical administrative ability, and in common-sense, he is equally eminent, and, like all good civil servants, his modesty and self-effacement have been such that the credit of his good work has never seemed to belong to him. Into his private life he takes the warm admiration and good wishes of the whole profession, and we look forward with confidence to his receiving the titular distinction to which he is so eminently entitled. We think we may say, without risk of being misunderstood, that only the present President of the Board could have been gifted with sufficient imagination to have chosen Dr. Arthur Newsholme as his successor. The ways of the Civil Service are strange, and no doubt it will be disappointing to the distinguished gentlemen in the inspectorate that they will not receive their due promotion; but we may truthfully say that if Mr. Burns wished to go outside the present staff for a chief, he could not have chosen more wisely. Dr. Newsholme has not only great abilities, but great energy, and his work has never flagged for a moment. He is probably the most accomplished sanitarian in the public health service at the present moment, for as clinician, administrator, and statistician he is known and respected. We congratulate the Board on its new Medical Officer, and the new Medical Officer on the honour bestowed upon him. As with Dr. Whitelegge's appointment to the Home Office some years ago, it is well that the district medical officer of health should know that he carries the field marshal's bâton in his knapsack.

College of Preceptors and Hygienic Instruction.

THE late Mr. Spurgeon, when speaking of the religious efforts made to reach different strata of the community, was wont to speak of "the neglected upper classes," and applying the simile to the efforts now being made to bring the care of children and the hygiene of schools to public notice, we cannot but feel that the children of the poor are being affected far more by diffusion of knowledge on these subjects than are the children of the upper classes. True, school hygiene is penetrating some of the large public schools; Dr. Clement Dukes, who was a school hygienist before school hygiene was "discovered," has done yeoman work at Rugby; Canon Lyttleton has sensible ideas to inculcate in his new sphere at Eton; and University College and King's College Schools, in their respective new surroundings, both bear traces of the hand of the reformer. But in the private preparatory and secondary schools the light of the new gospel has yet to dawn, and we welcome very heartily the excellent efforts made by the College of Preceptors to bring it to the masters and mistresses engaged in those spheres by incorporating lectures by well-known teachers on such subjects as the care of school children's eyes, the hygiene of the ear and throat, and the training of the voice, into their meetings for teachers in the winter. The session of these vacation lectures has just closed, and we feel that the instruction therein given cannot but have a far-reaching effect. There is no reason why the upper classes should be "neglected" and we congratulate the College of Preceptors on its far-sighted wisdom in providing such courses. The principle is capable of almost indefinite extension.

Rough on Rats.

"AUTREFOIS le rat de ville,
Invita le rat des champs,"

we all learned in our youth from Lafontaine, but we did not realise all the dread potentialities of plague and other abominations which lay in that exchange of civilities. Time, however, has shown that the urban trend of the rat community has been as marked as that of the British population since the Cobdenite era, and that the rat flourishes amazingly on the off-scourings of human habitations. We have every sympathy with the Society for the Extermination of Vermin, which has lately inaugurated its existence by a public gathering under Sir James Crichton-Browne, and we wish them all success in their efforts, except, perhaps, that of distorting the English language to the extent of making the word "vermin" cover mammals. Nothing in the world is done without enthusiasm, and the task of exterminating rats, or reducing their number to any sensible degree, will make great demands on the amount of that valuable quality possessed by the members of the Society, so that we do not like to throw cold water on the scheme; but we cannot help feeling that the crusade is not without its Quixotic aspect, and that the rat-pursuers are in for a long job. Moreover, they may be in actual peril of prosecution, for the philthereutists who value the lives of animals above those of "humans," may find that rats cannot be pursued without torture or killed without torture, and the destroyer may be publicly pilloried to show what kind-hearted people the pro-ratters are.

Minus = Plus.

IT would certainly be a delicate question to decide as to whether a rat was *feræ naturæ* or not, for while the animal is not wanted for domestic purposes, he certainly makes himself very much at home when he attaches himself to a dwelling; but, happily, it is not necessary now to prove ferocity—have we not recently learned that eggs may be *feræ naturæ*?—and the ratter could probably be haled before the beak if he harried the "vermin." It is estimated, we do not know on what basis, that the London Docks contain six million rats, so that the field is large and the opportunities for distinction many, and we should suggest that Saturday afternoon rat hunts might provide a healthy and congenial pastime to oafs who do not become muddied, but sit watching others who do. However many victims are brought to the slaughter, it is disheartening to relate that no appreciable diminution of the pests is likely to occur, for Mr. Haffkine lately said that with regard to the anti-plague campaign at Tokio, that although nearly five million rats were killed, the slaughter only seemed to prepare more favourable conditions for the multiplication of survivors. Whereas, therefore, a campaign waged with all the panoply of sticks, guns and dogs would give amusement to many, and would result in thousands of casualties, the net effect would, on this analogy, merely lead to the survivors having a better time and more opportunity for breeding. Although we lend our blessing to the cause of extermination, we do so without any illusions about the nature of the task.

International Union of Medical Abstainers.

We have received from Dr. J. J. Ridge, President of the Council of the International Union of Medical Abstainers, a notice setting forth a scheme which that Union has prepared with the object of solving the value of alcohol in lobar pneumonia and enteric fever. "The statistical method can alone accomplish this, as it eliminates the personal element, and the fallacy inevitable *(sic)* due to small numbers and personal prejudice. A large number of cases must be collected, some treated with and some without alcohol." Let us say at once that we should cordially welcome the right solution of the use of alcohol in these diseases, and that we have no doubt that the International Union of Medical Abstainers are animated only by the highest motives. But is it not obvious that any such investigation must be conducted in an unbiassed and purely scientific atmosphere? That is, if it is to be accepted as authoritative by the profession, the work is not one for a partisan organisation to undertake. Everyone knows, *à priori*, how they wish the result to come out, and everybody knows the danger of accepting conclusions arrived at by well-wishers of one side. We may put a publican on a commission to inquire into the amount of drunkenness in the land, but we should be loth to accept the conclusions of a commission composed entirely of brewers. We should give great weight to representations made by the Society for the Prevention of Cruelty to Children in an inquiry as to infant neglect, but we should not, if we wished to make a full and complete inquiry, entrust it solely in the hands of the Society's officials. In a word, professionalism is too strong for even the best of us.

And its Scheme.

Now, although it is true that the question of the value of alcohol can only be settled by the statistical method, it is equally true that Queen Anne no longer exists. All questions can only be solved by the statistical method, that is, the method of collective experience. The difficulty is to get pure figures. Now, the plan laid down by the Union seems to us about as unlikely to obtain pure figures as any that could be devised, and as certain as possible to lead to hopelessly wrong conclusions. It is that the participants in the scheme shall bind themselves for a year to treat each case of pneumonia and typhoid fever in their practice alternately with and without alcohol! May we not take this as an example of the incapacity of any partisan body to arrive at correct conclusions? Every alternate case is to get alcohol, whether it needs it or not, apparently, and the others are to be treated without it, whether they need it or not, also apparently. We have no hesitation in describing an experiment conducted on these lines as opposed to the best traditions of the profession; no man who sets out to treat serious cases on a plan such as this can have the individual interest of the patient as his only motive. That consideration alone is enough to deter anyone from joining the investigation, and if it were not, the fact of having to give alcohol to patients who do not need it in order to keep to the alternate arrangement is a sufficient reason for showing how the results are stultified *ab initio.* We beg the International Union of Medical Abstainers to reconsider this ill-devised scheme.

LEADING ARTICLES.

LAW REFORMS AND THE MEDICAL PROFESSION.

The law of the British realm is a marvellous structure, which has grown by the slow additions of many centuries into a tangled congerie of precedents, statutes and procedure that in their entirety may well constitute the despair of the most expert legal student. For all that, its foundations are so solid and the national character so inherently conservative and law-abiding that the administration of justice in the United Kingdom compares favourably with that of any other country in the world. Signs are not wanting, however, that the day of legal reform is at hand. One of the chief complaints against our national system of judicature is its real costliness, an objection that is fatal to the ideal of justice, for it should be absolutely accessible to every subject in the realm, regardless of his position in society. Turning to medical testimony, with which our readers are more directly concerned, it is of some interest to inquire to what extent their interests are involved in the question of law reforms. The subject is far larger than might at first be anticipated. Medical evidence is required daily and universally in courts of law of all kinds, from the coroners' and police courts up to the King's Bench and Chancery. There are various points with regard to the nature and amount of fees, of the privileges of expert witnesses, of the exacting of gratuitous testimony, of the suppression of the rights of medical witnesses by coroners and by county councils acting through coroners, of the exclusion of medical testimony by unqualified persons, and many other apposite things that demand attention. But of all the coming reforms, there appears to be no single one of more direct and urgent importance than that which asks for some readjustment of the present system whereby opposing expert evidence is now tendered by both parties in a lawsuit. A more costly device for getting at the truth could hardly be imagined than that which brings into court on either side an imposing array of more or less eminent expert witnesses. As regards the status of the medical profession in the eyes of the public the present system is simply deplorable. No suitor need regard his case, however threadbare and forlorn to all appearances it may be, as hopeless, so far as the support that may be forthcoming from members of the medical profession is concerned. Some of the most notorious instances of the kind are to be found in the literature of "railway spine." It is no exaggeration of facts to say that any person who has been present in a railway collision may reckon with confidence on finding a certain number of prominent medical witnesses ready to come forward in court in support of his claim for damages. What wonder if the public looks on with cynical amusement at the spectacle of half a dozen bigwigs in the witness-box flatly contradicting half a dozen colleagues of equal standing upon matters of opinion. Worst of all is the commentary afforded by the lawyers' aphorism that the best treatment for "railway spine" is a swinging award of damages. The question of how so undesirable a position may be remedied is perhaps a little complicated, but it should not be above the wit of the average parliamentarian to suggest some way out of this particular tangle when the whole question of legal reform comes before the legislature. Why should not a body of experts be appointed to sit permanently and decide upon all medical points submitted to them for consideration? Their opinion would come to the courts concerned with the weight of unbiassed authority, a quality that is certainly wanting in the present rough and tumble conflict of expert witnesses who have been retained at great cost by the suitors on either side. Then, again, such an advisory body would naturally be under the control of a medical man of special skill and experience, who would, in point of fact, act as a specially skilled expert judge dealing with one class of evidence. It requires no labouring of the matter to show that his decisions would be infinitely more valuable than those of a judge who has had no medical training, and whose judgment, however clear and well-trained in legal matters, must inevitably fail in the complete and adequate grasp of such highly technical evidence as is necessarily involved in medico-legal issues. In former years the Medical Press and Circular has strongly advocated the institution of some kind of special assessment or judicial board to report upon and submit medical evidence to our courts of law. With the lapse of time the arguments in favour of that proposal have gathered strength, and it is to be hoped in the interests of a dignified and great profession like that of medicine that the matter has actually entered within the range of practical politics.

THE MEDICAL EXAMINATION OF SCHOOL CHILDREN.

The details of the administration of the Act relating to the medical examination of children in the public schools are not likely to be settled without considerable discussion in various parts of the kingdom. The main points around which differences of opinions seem to centre are, first, the cost of the machinery, and, secondly, as to whether the special duties should be performed by a staff of officials appointed *ad hoc* or by local medical practitioners. The County of Durham recently discussed the matter in a large representative meeting held at Durham to consider which of the two methods mentioned above would be preferable. One was that a special medical officer should be appointed to devote his whole time to the work, and the other was that it should be done by various medical men, who should give part of their time only to the work and be paid so much per head. The representatives of the county favoured a scheme by which the county would be divided into five districts, with a medical man appointed to give his whole time to the work in each of the districts. There were objections raised to this method on the ground that it would be too expensive and would mean an increase of officialism. In regard to Sunderland, a delegate suggested that the town should be divided into five districts, and that for each a doctor in ordinary practice should carry out the work and be paid according to his services, and that the whole of the work should be under the supervision of the Medical Officer of Health. This last point is considered an important one, owing to the power it would give to the Medical Officer to go into the homes of the people. There is, of course, something to be said in favour of each proposition. On the whole, that scheme would probably be most widely acceptable which engaged men who are kept in touch with the ailments of children by the contact of daily practice. In any case, the necessity of supervision by the Medical Officer of Health would seem to be an essential to smooth and efficient working of the system. A day or two after the Durham meeting the Stafford Town Council unanimously adopted a strong resolution, which advocated the appointment of local practitioners with no uncertain voice. The resolution ran: "That the Town Council of the Borough of Stafford are much concerned and alarmed at the ever-increasing expenditure of the Education Committee of the county, and hereby protest in the most emphatic manner against the proposal to appoint a staff of medical men to carry out the duties of the Act lately passed, necessitating the periodical medical inspection of school children; that in the opinion of this Council such appointments are extravagant, as they consider that the work can be done by the present medical men in the county quite as efficiently and at a much less cost." The arguments advanced by Alderman Wright, who proposed the motion, are worth reproducing as representing the last word on one side of the question. Local medical men, he submitted, would be far more likely to know the needs, the surroundings, and the probable health of the children. If other medical men were imported there would be a dual medical authority, and the result would be anything but satisfactory, as they would come in conflict with the sanitary authorities, who were responsible for the health of the district. It seemed to him that the County Council had jumped to a conclusion, with their well-known love of luxury and expenditure, of dealing with the matter in the most expensive way. The costs would amount to thousands of pounds per annum. The education rate was formerly 8d. in the pound, and it was now 1s. 5½d. in the pound, and that amount represented an expenditure of £6,000. If the Pottery towns became federated it would mean a large ratepaying area being taken from the county, and the probability was that it would have the effect of largely increasing the education rate. He came to the conclusion that unless the public authority took steps to curb the expenditure and the love of throwing money away lavishly by the Education Committee, they would go on until the rates were unbearable in the town, and residents would have to follow the example set by the tradespeople of Wolverhampton by going out of the town to avoid the heavy rates. From the point of view of the general practitioner it would seem advisable that they should take immediate steps not only to grasp the facts of the situation, but also to communicate them to the fellow-ratepayers of the district in which they reside. Otherwise they may find themselves deprived of the enjoyment of a number of lucrative posts to which they seem *primâ facie* to have some sort of claim. In any case, it seems fairly evident that the ultimate issue will depend to a great extent upon general practitioners themselves. It would be difficult to imagine a practical issue that is more pertinent to the ends and aims of collective defence and advancement of bodies than the disposition of a vast number of public appointments of the kind that must inevitably be created on a large scale within the next few months.

CURRENT TOPICS.

The Ancient Philistines and Rat-borne Plague.

MODERN science is constantly reminded of the ancient saw which asserts that there is nothing new under the sun. If there be one discovery more than another upon which the medical man of to-day plumes himself, it is that which traces the spread of Asiatic plague to the agency of rats. It appears, however, that the connection was recognised by the Philistines of Biblical history. It is recorded, for instance, that they were in the habit of offering in their temples golden boats and golden mice in order to celebrate recovery from the plague. The "mice" of the English translators is used as a generic term, and includes the black rat. A correspondent to the *Manchester Guardian* has drawn attention to the fact that, as was pointed out by a writer in a theological magazine a year or two ago, there is apparently a record of plague in the fifth and sixth chapters of the First Book of Samuel. The mortality among the Philistines was very heavy, and both those who died and who survived had the emerods or swellings. These were evidently the "buboes." The Philistines coupled the emerods and the mice together, taking the connection for granted. "One plague was on you all." Some interesting points on the bibliography of this point will be found in our Notices to Correspondents column.

Quis Custodiet?

THE question of members of the medical profession writing signed letters and articles to lay publications has become more than a mere troubling of the domestic waters. It has strayed into the wider field of public controversy, as many matters of ethical interest are wont to do. The first point raised by extramural journalists is why the general practitioner of Slocum-cum-Podger, who happens to administer first aid to a boy run over by the local butcher's cart, runs the risk of being "solemnly censured and grievously manhandled by the grave and heavy seigneurs who preside over the councils of the British Medical Council?" (*vide Onlooker*, 11th January), while Harley Street Magnates may contribute two signed columns on any medical subject they choose and go unscathed. Is there any truth in this flowery and sarcastic rhetoric? As a matter of fact, many signed articles by leaders of the profession, titled and otherwise, appear in the *Times* and other lay newspapers, and so far from condemning the practice, the Presidents of some of our Royal Colleges now and then join in the fray. Under these circumstances it is difficult to say what is the established ethical law upon the point. If the rule be to abstain from publishing signed communications on professional topics in non-medical journals, it certainly appears to be more honoured in the breach than the observance. If there is to be a law its application should clearly be universal.

"British Journal of Tuberculosis."

THE January number of the *British Journal of Tuberculosis*, which lies before us, maintains the high standard of its predecessors. Its "feature" consists of a series of articles on tuberculosis in the various military services, each written by a responsible and well-informed officer. Fleet-Surgeon Wenmoth Pryn, D.P.H., discusses "Tuberculosis in the Navy, 1860—1906," and completes his article by a very practical series of suggestions as to the construction and ventilation of ships. The idea that the sea is a good calling for the tuberculously-inclined is only true if the conditions of living on board a ship are at least as hygienic as those on land. "Tuberculosis in the Army, 1860—1906," is dealt with by Lieut.-Col. Charles Melville, M.B., D.P.H., who shows that there has been a great and practically continuous fall in the wastage due to tuberculosis in the period under notice, and notices the conditions responsible for the welcome change. Lieut.-Coloned R. J. S. Simpson, C.B., Professor of Tropical Medicine at the R.A.M.C. College, London, gives an analysis of the tuberculosis returns at various foreign stations in his paper on "Tuberculosis in the British Army on Foreign Service"; and Major C. A. Johnson, M.B., D.P.H., writes at some length on "Tuberculosis in the Indian Army." The same subject, as applied to the Egyptian Army, is dealt with by Captain Stevenson L. Cummins, M.B., and some most significant facts about the presence and absence of tuberculosis among native tribes are given. Several original articles by various authors also appear, and the "Health Station" described is Madeira and the Canary Islands. There are also many reviews of books on tuberculosis and preparations suitable for its treatment. Altogether, no one who is interested in the subject (and which of us is not?) can afford to neglect this interesting magazine.

Medical Fees in Probate Actions.

A JUDGMENT deciding a matter of some importance in regard to medical fees was given by the Court of Appeal in Dublin last week. It appears that an action had been heard arising out of a disputed will, and the executors in their table of costs had included two items of four guineas each paid to two medical men for consultation and report on the mental condition of the testator prior to the making of the will. The medical men had not been called on to give evidence in court, and the Taxing Master had disallowed the payments on the grounds that the reports were unnecessary, and "did not appear to have been of any benefit for the case." The executors appealed, and the court unanimously refused the appeal. Of course, the decision may rest on some special circumstances which characterised the case, but from the arguments used it would seem to have been influenced by general considerations. It was stated that neither of the gentlemen was an "expert," and that their relation to the case could only have been as testifying witnesses, speaking in regard to matters of fact which came under their notice. They had been brought into close relation with the testator by the fact that he had been in their hands for surgical operation shortly before his death, and they therefore had good opportunity for judging of his mental capacity. We entirely fail to see how knowledge gained by a professional relation of this sort is to be regarded as that of an ordinary witness, and we do not know why the report is not to be classed as the work of experts. As compared with the public, all medical men are "expert" in matters of their professional knowledge, whether they are specialists or not in the particular subject on which information is sought. The lesson to be learnt from the case is that medical men should insist on getting their fees in advance in all medico-legal cases.

Admission of Women to the London Royal College of Physicians.

An interesting departure was made in the history of the Royal College of Physicians of London on Friday last, under the presidency of Sir Douglas Powell, Bart. After considerable discussion, by a large majority it was determined to admit women to the examinations for the licentiateship and the membership. The matter, however, is not, perhaps, so simple as it looks upon this bare announcement. Under existing conditions the licence cannot be given apart from the membership of the Royal College of Surgeons of England, as the two qualifications are now conjoint and indivisible. The conferring of the licence of the Physicians is therefore conditional upon the co-operation of the sister body in Lincoln's Inn Fields. As a matter of fact, the attitude of the Royal College of Surgeons appears to be by no means favourable to the admission of women. We understand that a circular letter has been sent to members in order to ascertain their views upon the matter. At present there are practically two avenues of approach to the membership, one being through the licence. Supposing that to be blocked by the Royal College of Surgeons, the remaining avenue, namely, that which throws open the membership examination to graduates of a recognised university, is now open to women. The avenue to fellowship is solely by election. A fresh complication is here introduced, inasmuch as the Fellows exercise some kind of disciplinary function over licentiates and members, and no women have been hitherto admitted to any body possessing powers of that kind. On the whole the only definite issue so far of last week's committee is that the membership is now thrown open to women who are graduates of a recognised university.

Lucidity and Scientific Teaching.

The discussion which took place a few weeks ago in the *Times* on the relation of the man of science to the public was one of considerable importance to all who hold that science should have an interest for the many, and not only for the few. The accusation that has been brought against the English mind of being slow to apply scientific knowledge to practical affairs seems to have some justification. In the realms of public health, of education, and even of industry, other countries have been more rapid in applying the results of scientific research. This is not due to any poverty of scientific intellect in these countries, for our men of science—as men of science—stand as high as those of any country. There are various grounds for it, but one, which seems capable of alteration, is the lack of interest shown by the public in matters of science. For this lack of interest men of science are to some extent to blame, for they often act and speak as if science were something esoteric, and not to be communicated to the vulgar. As a nation we have peculiarly few scientific teachers possessed of the gift of lucidity in exposition. A comparison of our leading reviews with those of France will show how poor in scientific articles are the former, and how deficient in literary grace are the articles which appear. We require more teachers like Tyndall and Huxley, men who were not merely leaders of scientific thought, but are also great writers and expositors. Even in the past few decades we seem to see a falling-off in the literary abilities of writers on scientific subjects, and there are few medical men, for instance, writing in English at the present day possessed of the style of Paget, of Wendell Holmes, or, to mention one still with us, of Weir Mitchell. The power of lucid exposition will have to be cultivated if science is to take its rightful place in the practical affairs of the nation.

PERSONAL.

Dr. Joseph Beard has been appointed School Medical Officer to the Bootle Town Council.

Dr. A. K. Chalmers has been appointed Examiner in Vital Statistics to the University of Glasgow.

Mr. T. H. Bickerton has been elected President of the Liverpool Medical Institution, and Dr. John Hay Editor of its journal.

Mr. Robert E. Kelly has been appointed Assistant-Surgeon to the Liverpool Royal Infirmary, in place of Mr. R. A. Bickersteth.

Col. David Bruce, C.B., D.Sc., F.R.S., will lecture at the Royal Institution next Friday on "The Extinction of Malta Fever."

Dr. T. G. Nasmyth has resigned his position as Medical Officer of Health of the Counties of Fife, Kinross, and Clackmannan.

Professor Kleine, for many years assistant to Professor Koch, is being sent by the German Government to East Africa to study sleeping sickness.

Dr. F. J. Henry, on leaving Glasgow to take up the post of Medical Superintendent to the Highfield Infirmary, Liverpool, has been presented by his colleagues with a gold watch and chain.

The President of the Local Government Board has appointed Dr. Arthur Newsholme, F.R.C.P.Lond., as Medical Officer to the Board, on the retirement from that office of Mr. W. H. Power, C.B., F.R.S.

The annual dinner of the Royal College of Surgeons in Ireland will take place on Saturday, February 1st. Tickets, one guinea each, may be obtained of Mr. G. F. Blake, Registrar.

Yesterday the Lord Mayor of Liverpool, on behalf of the Royal Humane Society, presented Dr. Peters with a medal for pluckily saving a person from drowning last summer at Amlwch, Anglesey.

The Secretary of State for the Colonies has appointed Dr. W. J. Simpson, Professor of Hygiene at King's College, London, and Lecturer in Tropical Hygiene at the London School of Tropical Medicine, to proceed to the Gold Coast to assist in combating the present outbreak of bubonic plague at Accra.

A CLINICAL LECTURE
ON
EMBOLISM CONSEQUENT UPON LESIONS OF THE LEFT HEART.

By PROFESSOR PAUL CLAISSE, M.D.,
Physician to the Pitie Hospital, Paris.

[Specially Reported for this Journal.]

A person has an attack of rheumatic endocarditis somewhere about the fifteenth year, inflicting permanent, incurable damage, and since that time there has been shortness of breath on exertion. Ten years later he has fugitive hemiplegia, which clears up in a few hours. Then, more recently, there is another attack of right hemiplegia, with aphasia.

These few words sum up the history of one of our patients whom you have just seen. On examining her, we find well-marked mitral stenosis, and we are driven to the conclusion: cerebral embolism following mitral stenosis. With a few differences, much the same condition of things obtains in the patient in the next bed, and only a day or two since another one succumbed under much the same circumstances, the pathological specimens whereof are before me.

You see, then, that in a single ward, within a few weeks, we have had three cases of embolism following mitral lesions.

This is consequently a clinical fact of, so to speak, daily occurrence, one with which we ought to be perfectly familiar. Everyone ought to have very clear ideas as to its origin, the mechanism of its production, and its consequences, in order to be in a position to formulate rational prognosis and treatment.

Yet, when we go into the question rather more deeply, we find that the text-books only give very brief details concerning it, and we are fain to glean our information from various publications, among which I may mention the recent theses of Grabias, Gireaux (1904), Guillaumin (1905), Boutin (1907), Ginsburg's work (a), and an excellent article by Barié (b).

Lesions of the left heart are frequently the source of emboli, and Ginsburg, who investigated a large number of heart cases from the point of view of embolism, estimates the proportion at something like 34 per cent. of all cases of embolism. It must, therefore, be regarded as a very important clinical circumstance with which we must familiarise ourselves in all its phases, in the striking cases of large arterial obstructions as well as in its occasionally more discrete manifestations in the form of visceral localisations.

This complication is not equally common in all forms of heart disease, and the same statistician tabulates the following figures: mitral stenosis, 43 cases; regurgitation, 11; double mitral lesion, 6; aortic lesion, 5.

To what must we attribute the preponderating part played by mitral stenosis? In order to understand this, let us inquire into the origin of the embolus.

Sources of the Embolus.

The solid mass, the embolus, which is about to be thrown into the arterial circulation, is sometimes formed of endocarditic vegetations, pathological products more or less of old standing, of variable size, torn from the ventricular walls by the blood current. This endocarditic embolus is common to all forms of heart disease, and is met with just as well in mitral as in aortic lesions. As a rule it is rather small, and is not the cause of the grand syndrome of arterial obstruction. The latter results usually from the migration of a cruoric or fibrinous clot of uncertain age. Now the formation of clots is a very complex phenomenon, and is the outcome of three different sets of conditions.

1. *Coagulability of the Blood.*—This varies within wide limits in different subjects, and even in the same individual under changing conditions (inter-current disease, influenza, typhoid fever, etc., the action of drugs, such as chloride of calcium, gelatine, etc.). I do not propose on this occasion to tackle this big subject. I will merely remark that in a subject who is predisposed by heart disease such circumstances may decide the matter, and pave the way to the formation of a clot. We may draw one practical conclusion therefrom—viz., that in the event of hæmorrhage in a cardiac subject we must avoid all measures for the arrest of the bleeding, which would have for effect to exaggerate the coagulability of the blood, consequently we shall not prescribe either gelatine or chloride of calcium.

2. *Changes in the Walls.*—Experiment has proved that blood coagulates more readily if, instead of running over a smooth surface, it comes into contact with a rough wall that has been damaged by previous changes.

3. *Blood Stasis* is the true determining cause of clot formation, the causes just mentioned, after all, only predisposing thereto.

Now these three conditions are not equally fulfilled in all forms of heart disease. The first two, which comprise changes in the fluids and walls, are not specially associated with this or that structural change, and may exist just as well in connection with mitral as with aortic lesions. Blood stasis, on the other hand, is hardly likely to be present save in mitral stenosis. We know as a fact that any diminution of the calibre of the mitral valve has for immediate effect to provoke dilatation of the left auricle, the pouch thus formed not being able to empty itself at each presystole. Eddies take place in the mass of blood in the axis of the orifices and the peripheral parts of this sphere of blood, which are not properly renewed, are in a state of comparative stasis. Very different is the state of the blood within the ventricle in the subjects of mitral or aortic regurgitation. Here, on the contrary, in addition to the natural propulsion, there is a to-and-fro movement that increases the churning of the blood. The blood stasis caused by mitral stenosis is therefore the principal cause of the tendency to clot formation, and thus we get the relationship of cause and effect between mitral stenosis and embolism in the aortic domain.

Migration of the Embolus.—The clot thus formed may be expelled forthwith, or, on the contrary, it may become adherent to the walls; attached for a time to endocarditic vegetations, it may become organised and fibrinous. This distinction between recent cruoric clots and old fibrinous clots is not without its importance, as will be shown later.

Well, then, the clot leaves the heart, becomes an embolus, and wends its way into the aortic territory. Its size will decide the distance it is to travel. If of very large size it will be caught by the spur of the first bifurcation—that is to say, in the abdominal aorta. If of less dimensions it will take up its residence in the carotids, the brachial or the femoral artery. Small clots will plug the Sylvian artery, the arteries of the forearm or leg, or some visceral artery. Lastly, there are extremely minute capillary emboli which also call for notice.

I need not dilate on the symptomatology of massive obstructions of the large arteries of limbs, which are fully described in text-books. We are familiar with the syndrome characterised by sudden pain, which may be of agonising severity, associated with tingling, a sensation of cold, functional impotence, and abolition of the pulse in the affected area.

(a) *Deutsch. Archiv. fur Klin. Med.*, 1901.
(b) *Presse Medicale.* Feb. 3rd. 1906.

We are also familiar with the common clinical picture of rapidly fatal cerebral ictus, or, as in this case, of hemiplegia, usually on the right side, with aphasia, or, again, with sensory disturbances corresponding to arterial obstruction in the centres or in the organ of sight or hearing.

In short, embolic obstructions of the arteries of limbs and also of the brain are, as a rule, easy enough to diagnose.

This is by no means the case in visceral embolism, which may readily be overlooked or be mistaken for something else.

Renal embolism, for instance, which is by far the commonest form, is very often overlooked, and provides us with a surprise post-mortem. Sometimes it is ushered in by a violent feeling of something giving way in the lumbar region, like the pain of nephritic colic, but it often happens that the pain is altogether wanting. Albuminuria, hæmaturia, and anuria are also inconstant signs.

Whatever renal symptom may be observed, the only thing we can rely upon for the diagnosis is the suddenness of its occurrence in a cardiac subject. No one sign possesses a pathognomonic value, and we are often reduced to hypothesis.

The same remark applies to splenic embolism. Sometimes it is quite latent; sometimes, on the other hand, it gives rise to intense organic reaction. Boutin records a case of splenic embolism characterised by severe abdominal pain, tympanites, vomiting, and rapid pulse, which was diagnosed as peritonitis.

Large emboli of the liver or stomach are of rare occurrence. As to small emboli, they, no doubt, play their part in the digestive pathology of cardiac subjects; but it is difficult to specify what part they play in view of the predominance of hepatic, venous congestion, which may mask all secondary lesions of minor importance.

Mesenteric embolism gives rise to striking clinical phenomena, and I can recall a very interesting example thereof in this ward. A woman, suffering from mitral stenosis, had been admitted a few days previously, when "she was suddenly seized with extremely severe symptoms, complained of intolerable pain in the belly in the middle line, near the umbilicus, which radiated into the iliac fossæ and even into the lower limbs. It was so severe that the patient, bent double and incapable of the slightest movement, positively howled with the pain. After a time the patient passed a diarrhœic motion, floating on which were shreds of intestinal blood-stained mucous membrane. There was tympanites, she broke out in cold sweats, the extremities became cyanosed, and she died in the afternoon."

This sudden, violent abdominal pain, followed by glairy hæmorrhagic diarrhœa, is usually met with in cases of mesenteric embolism, and enable us to arrive at the diagnosis when the victim is the subject of heart disease.

Results of the Embolism.—Embolism is followed either by total, permanent obliteration of a whole arterial territory (if it be a terminal or very big vessel), or merely by interference with the local circulation, should there be collateral vessels capable of relieving the results of vascular obstruction. In the first case we get dry or moist gangrene, by a combination of aseptic necrosis and secondary infection, a process which I recently discussed in connection with diabetic gangrene. Secondary infection of the embolised territory by surface microbes explains the enormous differences that obtain between various kinds of embolism. Let us take the kidney and spleen, for example, these being aseptic organs without any natural communication, with a possibly microbial focus. If any one of their arterial areas is obstructed by an embolus, degenerative lesions will follow: simple necrosis or infarctus, which then passes through the usual stages of retrogression. Then let us consider an arterial area bounded on one side by an infected surface (skin or intestinal mucosa). Here the transformation of the infarctus into a putrefactive area is the rule, because these areas, cut off from the circulation (and consequently from oxygen), constitute an excellent culture medium for the anaerobic microbes of putrefaction.

In some cases gangrene supervenes forthwith with remarkable promptness, and appears to be the direct consequence of the embolism by the migration of septic organisms. These septic emboli, too, explain certain cases of deep suppuration, of visceral abscess of the kidney, or perirenal connective tissue, etc. We may be able occasionally to detect them, so to speak, in the act, in certain cases of infective purpura in which pneumococcal or streptococcal endocarditis gives rise to small microbial metastases which can be distinguished in sections of the skin after biopsia.

The *Prognosis* depends on the size of the embolus, its seat, and, lastly, on its nature. It is obvious that the gravity of the disturbance will be proportional to the extent of the obstructed area, and that a big clot is more formidable than a small one. But the *seat* of the embolism has an important bearing on the prognosis. Even a very small clot may quickly cause death; medullary embolism, for instance, is lightning-like. The course is not quite so rapid in the case of the intestine, but is pretty certain to culminate in gangrene of the walls. Renal and splenic embolism, on the other hand, if not too extensive, may be tolerated, possibly, indeed, without much reaction. In embolism of the limbs several things may happen. If the obstruction is situated at the root of the limb, gangrene is unavoidable, and will carry off the patient sooner or later, or necessitate a major operation. If lower down, below the junction with a collateral vessel, if, for instance, it leaves the deep femoral intact, the situation is not so grave, and a complementary circulation may be set up in time.

Then, too, the *nature* of the clot has a bearing on the prognosis. You must not suppose that every arterial obstruction is for good and all. This may be the case in respect of obstructions due to endocarditic vegetations and old fibrinous clots, but recent, freshly-formed clots may merely cause temporary blockage, subsequently breaking up and disappearing. This explains how it is that we see the blood current re-established in a limb that has become cold, numb, and inert, and why total hemiplegia suddenly disappears. This favourable termination is frequent. The patient we examined had had total hemiplegia some months since, which only lasted a few hours. These ephemeral obstructions, indeed, are tolerably common. Obviously no such result is to be anticipated if the embolism be of some standing, but in recent cases we must bear this capital fact in mind in respect of both prognosis and treatment.

Treatment.—Treatment can only be palliative in embolism of the viscera. Much more can be done in embolism of the limbs. If the lesion be recent, aware, as we are, of the possibility of absorption, we must do our best to promote the process, acting as rapidly and as energetically as may be possible. We may hesitate to move or massage a limb with a damaged artery, just because we are in the habit of enjoining strict immobility in a limb afflicted with phlebitis. But you will perceive, on reflection, that the two things are quite different. The venous clot, a centripetal embolus, if mobilised, passes into the right heart, and will give rise to the ofttimes grave disturbances of pulmonary embolism. The loosening of an arterial clot, which, on the contrary, is a centrifugal embolus, can only have good effects, since it will free the lumen of the large artery, and the fragments of clot can, after all, not go further than the capillary barrier.

In cases of recent embolism, therefore, energetic massage is strictly indicated. Giraux relates a case in which Gautru, in Merklen's wards, was enabled to re-establish the circulation in the femoral artery by several hours' massage.

If the embolism be of old standing, such measures are useless, and all we can do is to watch the progress of the lesions in order to decide at what moment and at what spot surgical intervention is necessary.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Robert Hutchinson, M.D., F.R.C.P. Lond., Physician to the London Hospital, Assistant Physician to the Hospital for Sick Children, Gt. Ormond Street. Subject: "Modern Theories of Diet in their Relation to Practice."*

ORIGINAL PAPERS.

THE SURGERY OF THE HEART AND PERICARDIUM.

BY R. REHN, M.D.,

Professor of Surgery, Frankfort-on-Main.

1. Diagnosis of Wounds of the Heart.—If after an injury of any kind the pericardium fills rapidly and becomes tense with symptoms of cardiac pressure, the diagnosis of wound of the heart is certain. The symptoms of tension are pains in the left arm, a feeling of oppression, precordial pain, especially on expiration, which is made worse by pressure over the heart. Often there are violent, especially left-sided, pains in the abdomen, pronounced reflex muscular tension of the upper abdominal muscles, and shortness of breath, although the lungs are free. The pressure on the heart causes cyanosis from the slightest to the most extreme degree, the cervical veins being more or less filled. The pulse is thin, sometimes even to vanishing. Face and extremities are cold. The shortness of breath gets worse, and becomes dyspnœa. The patient at last becomes soporose, or falls into a deep faint.

Free continued hæmorrhage from an external wound in the cardiac region points to extra-pleural wound of the heart, whilst a stream of frothy blood only points to hæmorrhage from the interior of the chest.

If the results of percussion in the early stages of filling-up of the pericardium are uncertain, Röntgen illumination, especially the stereoscopic, may lead to decisive conclusions. It distinctly shows the enlarged area of cardiac dulness and the presence of foreign bodies.

We may assume a wound of the heart with great probability when the external wound corresponds and the kind and direction of it allow such a conclusion, when, along with a hæmo- or hæmo-pneumo-thorax, abnormal sounds can be heard.

The sounds may originate extra- as well as intra-pericardially; even the signs of a pneumo-pericardium are not a proof of a wound of the heart. The diagnosis gains in certainty the more the precordial wound approaches the sternum—*i.e.*, the more fixed portion of the heart, or when the sternum is penetrated. A systolic rushing sound is of great diagnostic value, but is not heard too frequently.

2. The condition under the various wounds, and, above all, when foreign bodies remain sticking in the heart.

Injuries of the heart by needles are not without danger. A needle penetrating from without should be extracted as quickly as possible, and if one has broken off in the wound an attempt should certainly be made to extract it. But, on the other hand, a broken-off knife tip, or dagger, or other similar weapon, should be left undisturbed until the operator has exposed the parts sufficiently, as violent hæmorrhage immediately follows the extraction, and this may be fatal. Even in deep unconsciousness—without narcosis—the heart should be exposed, as on the pericardium being emptied of blood it usually begins to act well, and the faint passes off.

All injuries with symptoms of severe cardiac pressure demand at least pericardiotomy. The chief indication is the arrest of the hæmorrhage. In case of threatening internal hæmorrhage, even if there is no cardiac pressure, the pericardium should be exposed and an attempt be made to arrest the hæmorrhage, whatever the kind of wound may be.

There are a number of injuries where a wound of the heart is probable, without there being any urgent indication for operation. It is always better, however, to do an exploratory pericardiotomy, even if useless, than to overlook a wound of the heart.

Spontaneous recovery may take place in a certain percentage of cases. Wounds from needles afford a better prognosis than punctured wounds, the latter better than gunshot wounds; non-perforating wounds heal better than perforating ones. Nevertheless, a wound of the heart left to itself entails many dangers (purulent and non-purulent pericarditis, extensive adhesions, the danger of secondary hæmorrhage, bad, yielding cicatrices of the healed wound, so that it may break down or an aneurysm may form). A man whose heart has been sutured is therefore in a more favourable position than one whose wound has healed spontaneously.

The operation must be approached, however, with the greatest caution. In operations for gunshot wounds of the heart, it should be borne in mind that considerable injuries of the heart take place without perforation of the pericardium.

3. Exposing the heart and exploratory pericardiotomy.

Our procedure in exposing the heart is influenced by:—

1. The greater or lesser state of danger in which the patient happens to be.
2. The kind of wound and the position of the external one, whether right or left on the sternum, or at the side, at the back, or through the abdomen, or the absence of wounds and only contusions.
3. The accompanying hæmo-pneumothorax, or tension pneumothorax.
4. Elasticity or stiff rigidity of the thoracic walls, wide or narrow rib spaces.
5. Regard to the retention of a bony covering for the heart; this must stand in the front line.

It is of the greatest advantage to be able to perform the operation in a Sauerbruch's chamber or on a Brauer's table.

The ruling principle, however, must be to expose the heart in the most sparing manner possible. The use of the bone flap method should be restricted as much as possible. Bone flaps take it out of patients so much, and expose to great risk of infection. We should always try to attain our object at the least expense to the patient's safety, and nothing should be attempted at the expense of safe arrest of the hæmorrhage.

In other cases we must proceed more cautiously still. In a not inconsiderable number of cases the diagnosis is not quite certain. In a case, for example, where the external wound lies at a distance from the heart, exploratory pericardiotomy must be performed in such a way as will afford the greatest safety to the pleura, as well as for satisfactory evacuation of the pericardium.

The following plan fulfils these conditions:—

A crescentic incision runs along the lower border of the seventh left rib, about 6 cm. in length, towards the base of the ensiform cartilage and across it. The incision is deepened so that the costal cartilage of the seventh rib can be cut through just at its sternal insertion. The mammary artery is left untouched. Pushing the soft tissues aside, the finger is passed under the rib, and so between the musculus triangularis sterni and the sternal part of the diaphragm. The sterno-pericardial ligament is a good guide. With the cutting forceps a piece of the sternum and the cartilage of the seventh rib are resected. If, drawing back the rib and the sternum, the finger is passed directly upwards into the cellular tissue, the finger comes upon the pericardium, lying under a more or less thick layer of fat, and at a point where it is most likely to be free of diaphragmatic tissue. The more the pericardium is distended the easier the operation. But the operator must pass on upwards underneath the sternum in order to avoid opening the peritoneal cavity. It is extraordinarily easy to open the pericardium here, examine its contents, and thoroughly drain. The cavity may be emptied either to the right or the left, as from the same incision a drainage tube may be inserted from the right to left over the inferior vena cava. In this way the pericardium will also have been opened at its lowest part.

If whilst performing the pericardiotomy the operator has gained the impression that the heart itself has been wounded, he can proceed at once to lay open the heart by resecting the sixth rib at its cartilaginous origin.

Of the numerous methods of exposing the heart, I prefer the following:—First, an incision between the ribs, carefully observing the course of the external wound, passing from the sternum outwards. In case of a distant external wound, or of contusions, the incision may be made in the fifth internal costal space. In case of hæmo- or tense pneumothorax, the incision passes into the pleural cavity at once, the lung is grasped and drawn outwards, the ribs being drawn widely apart. The incision may be extended outwardly at pleasure. It will then be seen whether resection of one or more ribs will suffice, or whether partial resection of the sternum will be required. If it is found that the heart must be made still more accessible, as through free hæmorrhage from a wound below the sternum, then a longitudinal incision must be made in the sternum, and the soft parts freed. According to circumstances, the incision begins at the level of the upper border of the third rib, and ends at the upper border of the sixth. The costal cartilages of the ribs affected are cut through close to the sternum, and the bony flaps, along with the soft parts, are drawn forcibly upwards and downwards. The mammary artery need not be touched. If the pericardium is now opened by a vertical or a crucial incision, a good view will be obtained, and may be made more extensive by cutting off the border of the sternum. The heart can now be drawn so far forwards that the greater part of the right auricle, the coronary sulcus, the large arteries, the ventricles of both sides, and also the left auricle in part may be got at. If it is the intention to spare the pleura, the incision at the margin of the sternum must be made deeper, and the costal pleura and that of the pericardium must be separated step by step, the ribs separated from the sternum, and, if need be, resected. The pleura must be separated from the pericardium with the greatest caution, and in this way, in favourable cases, wounding of the pleura may be avoided.

4. Arrest of hæmorrhage in large wounds of the heart and suture of the heart.

When the heart has been exposed, in whatever way it may have been done, on opening the pericardium free bleeding may be expected. For the purpose of recognising the conditions that may be met with, the wound in the heart, a possible foreign body, and for passing the sutures properly, the parts should, if possible, be bloodless. In many cases where the bleeding is slight, it can be controlled by the finger; in other cases it may be so severe that there is danger of the patient bleeding to death, or of infection taking place. The possibility of being able to operate with but little or no blood in the way depends on the behaviour of the cardiac muscles, and the most sensitive nerve centres on diminished or entirely arrested blood supply. Experiments performed on dogs in the Pharmacological Institute, Heidelberg, have given the following results in regard to this:—

1. The bleeding from any wound of the heart may be arrested by compression of the right auricle, and by incomplete compression it may be mastered so that the sutures will pass through nearly bloodless tissues.

2. The dog's heart bears incomplete compression for four minutes with certainty, probably still longer; it bears complete compression for a minute and a half with certainty, but not longer than that.

3. The human heart will doubtless bear much more. In the dog's heart the flickering tremor is the deleterious feature, a sign of muscular insufficiency that can scarcely ever be recovered from in dogs; in rabbits and cats it is only fleeting.

Animal experiment, therefore, as well as experiences in treating the human heart, justify us in compressing the right atrium venosum in moments of extreme danger from hæmorrhage. It is best done by the finger. Whilst the heart is gently raised out of the pericardium with the right hand, the left hand is passed into the pericardium below it. The inferior vena cava, and its opening into the right auricle, are at once felt. It can be easily compressed between the ring and index fingers. By pushing up the finger the opening of the superior vena cava is closed. It is best, in passing the finger upwards, to go close to the inferior vena cava, so as not to close the vena magna cordis.

We have now the power of limiting or of completely arresting the blood current, and by means of this compression we can control the most rapid bleedings from the heart at once.

As regards suture of the heart, we can demand a good deal, but we must proceed as sparingly as possible. To grasp it with clamps or forceps would be serious. To bring the heart up to the chest wall by drawing on the pericardium is the most sparing method of bringing the heart into position for suturing. Too little of the side walls should not be grasped in doing so. If the heart is brittle the pericardium must be sutured along with it. Neither continuous suture nor wire should be made use of. The best is the interrupted suture with fine silk. A pause for rest should be given to a heart that is beating irregularly from exhaustion.

5. Statistics.—Of 124 cases of suture of the heart, 49 recovered, 75 died. Besides these, operations were performed on the heart without suturing in 10 cases, 6 for gunshot wounds, 4 for stabs, eight times with a favourable result, twice with a fatal one. Punctured and bullet wounds gave almost the same results. Wounds of the left ventricle were rather more frequent, and gave a rather higher percentage of recoveries; 16 patients had two wounds of the heart; in 1 case there were eight punctured wounds of the left ventricle, two of which were penetrating ones; in 12 cases the wounds did not penetrate, or it was not certain that they did so. The pleura escaped injury both from the wound and the operation in 9 cases (3 recoveries). The left coronary artery was ligatured or acupressed twice; both patients died of infection. If the case requires it, ligature of the main stem of the coronary artery must be attempted. A wound of the vena magna cordis must be treated by suture of its wall.

In regard to the question of drainage, the 90 available cases afford no distinct conclusion. The cases operated on extra-pleurally with drainage of the pericardium were the worst (all died); drainage of both cavities gave the best results.

It is always best to close the pleural cavity primarily, so long as bleeding that cannot be arrested does not call for tamponade. Before closing, the pleural cavity must be carefully emptied; during the first few days any air or fluid that has not been absorbed should be removed by aspiration.

The pericardium was closed in 50 cases (24 recovered, 26 died). It was drained in 40 cases (20 died and 20 recovered). In three of the cases of primary closure, the pericardium had to be opened and drained later on. Drainage by tampons led several times to retention of secretion, and once to strangulation of the heart with threatening symptoms. Rubber tubing is therefore best for drainage. The question to be weighed in each case after opening the pericardium is whether it will be better to close up or drain. If closure is decided on, the pericardium and the xyphoid cartilage should be sutured together so that the parts can be opened up and drained at any time. Complete closure of the pericardium with the pleura open is very dangerous on account of extension of infection.

As regards the complications in the cases that recovered (49), the after-treatment was more or less troublesome. Recoveries in 10 or 12 days are rare. The complications are pericarditis, which is very frequent, serous pleuritis, which occurred in several cases, pneumonia, empyæma in 6 cases, several times requiring puncture, resection of ribs and pleurotomy, delirium, psychoses, convulsive attacks, and pulmonary infarcts; secondary suture of the external wound, and a plastic operation on the chest wall, were each performed twice. As regards the complications and causes of death in the fatal cases, out of 75 patients, 16 died on the operating table, or within a few hours of the operation; 17 from within a few hours to two days after, from loss of blood and collapse, equalling 44 per cent.; 30 died from infection, or 40 per cent. The total mortality was therefore 84 per cent. In the future, infection will be avoided better by the use of Sauerbruch's process. The complications of pericarditis and pleurisy occurred in nearly 30 cases; in 12 of these the pericardium was closed primarily. Other complications were abscesses of the lungs, with pleuritis purulenta, pericardial adhesions, pulmonary infarcts with empyæma, phlebitis, purulent meningitis, five months after the operation, following cerebral abscess and encapsuled purulent pleuritic collection; partial subphrenic purulent peritonitis with purulent mediastinitis, commencing sero-fibrinous pericarditis, broncho-pneumonia, pneumonia, chronic myocarditis. Wounds were further found in the inter-ventricular space, and division of a thick papillary muscle of the tricuspid valve. In one case death took place suddenly, as from pulmonary embolism, although the patient appeared to be quite well on the morning after the operation. In another case there was embolism of the shot in the right subclavian artery, and ischæmic paralysis in the right forearm. In one case the projectile had passed through a vein of the lungs, had passed the heart, and been driven into the crural artery. One patient died on the eleventh day from tamponade of the heart, from a blood clot that had formed over a spot where a suture had been inserted; another one on the fifty-third day in consequence of unexpected hæmorrhage. On inquiry from other surgeons regarding the results in cases of suture of the heart, it was found that some patients could not be traced; some were dead from inter-current diseases. A post-mortem examination in one case showed almost complete adhesion of the pericardium to the heart; in another there were no adhesions at all. In a number of cases the patients were found, on later examination, to be perfectly strong and healthy. In one case examined ten months after operation it was ascertained that palpitation and occasional pain were complained of over the cardiac region, and the cardiac dulness was slightly extended on both sides. In another case a diastolic murmur was heard, and a partial aneurysm of the heart diagnosed two months after the operation.

As a casuistic contribution, the following case is given: A man stabbed himself in the region of the heart with a knife, 2 cm. of the tip of the blade being broken off. The conditions observed intra and post-vitam were the following: Extensive bleeding into the left pleural cavity, with compression of the left lung in connection with wound of the anterior wall and septum of the right ventricle at the commencement of the conus pulmonalis. The heart was sutured. There was slight thrombotic deposit over the inner surface of the right ventricle, acute sero-fibrinous pericarditis with left-sided pleurisy. The pericardium was sutured. The fourth and fifth costal cartilages were divided, with secondary reunion of the fourth afterwards. Excessive meteorism of both stomach and intestines, œdema of the lungs, commencing inflammatory œdema in the left lower lobe, circumscribed atelektasis of the right lower lobe, caseous tuberculous patches and cicatrices of the right apex of the lung, anæmia of all organs.

LUMBAR PUNCTURE IN AFFECTIONS OF THE NERVOUS SYSTEM.

By ALFRED S. GUBB, M.D.Paris, M.R.C.S.Eng.,

Of Algiers and Aix-les-Bains.

[Specially Reported for this Journal.]

Introduced for therapeutical purposes, lumbar puncture has become a means of diagnosis capable of rendering very great service in many affections of the nervous system. It enables us to establish the existence and the nature of attacks of meningitis, and it reveals the slightest disturbance of the cerebro-spinal axis and its membranes. It is now in constant use, and the *modus operandi* should be familiar to every practitioner. To Quincke, a Kiel practitioner, is due the credit of having first practised lumbar puncture, in 1890. Between the terminal cone of the spinal cord, covered by the pia mater, which stops opposite the second lumbar vertebra, and the cul-de-sac of the dura mater which ends behind the second sacral vertebra, there is a sort of reservoir, measuring from 20 to 25 centimetres in length, and 2 centimetres in width, filled with cerebro-spinal fluid in which float the nerves of the cauda equina. A trocar introduced through the third, fourth, or fifth lumbar spaces may be pushed into this cavity without any risk of injuring the cord. Quincke used to withdraw a certain quantity of fluid in cases of hydrocephalus in order to reduce the intra-ventricular pressure, and thereby abolish the symptoms to which this pressure gave rise. As a mode of cure this intervention was soon found to be of [illegible] value, and applicable in comparatively few [illegible] lumbar puncture would no doubt have been given up had not certain observers (Furbinger, Stadellmann, Bonome, Netter, Widal, Sicard and Ravaut), in the course of investigations on the normal properties of cerebro-spinal fluid and pathological modifications of the same, converted it into a means of diagnosis in affections of the nerve axis and its membranes. It has since been rendered an easy and trustworthy method of investigation which has come into daily use.

Technique.

The technical procedure is simple enough. With the patient in the sitting posture and slightly bent forward, or lying on his side with his head on a cushion, the thighs well flexed on the abdomen and the body bent forwards, the spinal processes are separated from each other, leaving a space of about half an inch. The sitting posture, recommended by some observers, is objected to by others on the ground that it allows of the too rapid escape of the fluid, fatigues the patient, and tends to set up muscular contraction. All that is required is an iridio-platinum needle, 3½ to 4 inches long, and 1-30th of an inch in thickness. One end is bevel-pointed, and the other fits on to the nozzle of a hypodermic syringe. The needle is sterilised by boiling or in the autoclave, and the skin over the selected spot is carefully disinfected by washing with soap and water, followed by ether and alcohol. The operator, placing his first finger as a guide over the fourth lumbar spinal process, which is just below a line drawn from between the two iliac crests, plunges the needle into the fourth space, just below the left index, about a fifth of an inch from the middle line, directing it slightly upwards and inwards. It successively pierces the sacro-lumbar muscles, the ligamentum sub-flavum, the vertebral canal, and the dura mater, entering the sub-arachnoid space.

The operation is peculiarly easy in the child, whose spinal column is more flexible, the ligaments less resistant, and the intervals between the vertebral arches comparatively much wider than in the adult. All we have to do is to plunge the needle boldly in the middle line, bearing in mind that in the child the cord comes down to the third lumbar vertebra. Even in the adult the median puncture is feasible, and is now often resorted to. The liquid having been allowed to escape, the needle is quickly withdrawn and the small orifice closed with a collodion dressing.

Should the needle butt against the wing or the base of the spinal process, all we have to do is to turn the point somewhat downwards and outwards, when it will go in readily enough. Should it strike the body of the vertebra, it must be withdrawn a little way, when we shall fall into the cavity. Should it get blocked, the lumen may be cleared by running a sterilised piece of wire through it. The first few drops of liquid are often tinged with blood, but the liquid soon becomes clear again. If it does not, the needle should be withdrawn and introduced afresh.

The patient may complain of sharp pain in one or both sides due to traction on some fibres of the cauda equina, but it soon passes off. If we take the precaution to place the patient on his back and to allow the escape of only a small quantity of fluid, we avoid the risk of possibly fatal syncope or other troublesome manifestation. Under ordinary circumstances slight headache is the worst that happens, and in bed this is not long in passing off.

Persons suffering from meningitis and, in general, those with excessive pressure of cerebro-spinal fluid, bear lumbar puncture better than the others, and complications are very rare with them. On the contrary, their symptoms are *pro tanto* improved. By modifying the intra-cranial pressure, lumbar puncture obviates its effects. Comatose patients regain consciousness and ask for food, convulsions cease, and actual aphasia may disappear completely and at once. In meningitis lumbar puncture does not act exclusively by relieving pressure, for the withdrawal of even a small quantity of the fluid, whatever its actual virulence, diminishes the infection and promotes organic resistance.

But the therapeutical action of lumbar puncture, whether palliative or curative, is insignificant compared with its diagnostic importance. Under the influence of bacteriological research, there has been a return to humoral views. Investigators have studied the composition of the various fluids of the organism in order to determine their normal properties and their morbid reactions, and they have obtained some highly valuable diagnostic data. The study of the cerebro-spinal fluid in particular has yielded a whole series of means of investigation of the greatest utility in the observation of meningeal lesions, and especially in tuberculous meningitis.

Normally, the cerebro-spinal fluid is alkaline, clear as crystal, containing but a small proportion of saline constituents, and not spontaneously coagulable; sp. grav., 1,003 to 1,004. Wolff gives the following analysis:—

Water, 985.64; chlorides of soda and potash, 8.01; albumen, 0.88; osmazone, 4.74; mineral salts and free phosphate of lime, 0.36; carbonate of soda and phosphate of lime, 0.17.

It contains no cellular elements. It is hypertonic compared with blood serum. Its freezing point varies from 0.58° to 0.75°. Quincke estimates its pressure at 40 to 60 millimetres of water; Leukowicz at from 20 to 25 m.m. of mercury. The physical and chemical characters of cerebro-spinal fluid vary in different pathological states.

Macroscopical Appearances.

The liquid may remain clear; this is usually the case in tuberculous meningitis, sometimes even in acute meningitis, almost always so in the meningeal processes associated with tabes, general paralysis, etc. It is often turbid and even purulent, as in most instances of acute meningitis. Lastly, it may be yellow or blood-stained. Apart from the presence of blood due to puncture of a cutaneous, muscular, or rhachidian vein, the presence of red corpuscles in the cerebro-spinal fluid is indicative of intra-meningeal hæmorrhage, the source of which may be elicited by inquiry—fractured skull, cerebral hæmorrhage, etc. In cases of hemiplegia the existence of this blood-stained fluid enables us to discard the hypothesis of softening, which is not accompanied by meningeal hæmorrhage. Simple yellow colouration does not justify a diagnosis of hæmorrhage of the neuraxis or its adnexa, for it is also met with in jaundice and in certain cases of meningitis.

Permeability of the Meninges.

Certain substances, when ingested or injected beneath the skin (iodide of potassium, methylene blue, salicylate of soda, etc.), only find their way into the cerebro-spinal fluid in certain meningeal inflammations. Widal, Sicard, and Monod have discovered iodide of potassium in the cerebro-spinal fluid in the course of acute meningitis, while Griffon and others have failed to find it in cerebro-spinal meningitis. In reality this permeability of the meninges, according to the theory of the earlier writers, does not possess any absolute diagnostic value. When it exists it indicates a meningeal reaction, probably, but not certainly, tuberculous, for it has also been met with in acute syphilitic meningitis. Its absence does not prove anything, for it is only present in half the cases of tuberculous meningitis.

Cryoscopy.—The cerebro-spinal fluid is often hypotonic compared with blood serum in acute meningitis, and especially in tuberculous meningitis. This hypotonicity is inconstant, and varies from day to day even in the same subject.

Tension.—The pressure of the cerebro-spinal fluid is measured by the manometer, or, roughly, by the jet when punctured. It is increased in certain meningeal irritations (acute meningitis and syphilitic meningitis), and in affections such as cerebral uræmia, secondary syphilitic headache, cerebral tumour, hydrocephalus, etc. The relief afforded by puncture to the headache suggests that the excessive pressure was the underlying cause of the latter. In short, the pressure of the fluid possesses a pathogenic and therapeutical rather than a semiological interest.

Chemical Composition.—The proportion of chlorides may be reduced in cases of meningitis. The proportion of albumen increases in presence of inflammation, especially of the meninges. It consists in that case principally of serine, whereas normally it is *mostly* globuline. The fibrin is increased in meningitis, urea in uræmia, and sugar has been found in the cerebro-spinal fluid of diabetics.

Cytoscopy.—The cytoscopic examination of the cerebro-spinal fluid affords valuable information. The presence of leucocytes in great numbers (50 to 100 and upwards per cubic millimetre) constitutes anatomical evidence of a meningeal lesion—(*a*) acute—when the infection that has set up the meningeal reaction is massive and brutal in its action, there is an outpouring of leucocytes which are the fighting cells; when it is sub-acute from the onset, or when it is retrogressing towards recovery, there is lymphocytosis. In tuberculous meningitis lymphocytosis is usually present, sometimes associated with polynucleosis, due, no doubt, to its microbial associations. Moreover, if we stain the preparations by Ziehl's method, in about half the cases one discovers a few tubercle bacilli, and that, of course, establishes the diagnosis.

In acute non-tuberculous meningitis there is usually polynucleosis, while in meningitis tending towards recovery, in acute syphilitic meningitis and in typhoid meningitis we may find lymphocytosis. It will be seen, then, that lumbar puncture allows us to distinguish meningitis from the nervous phenomena of uræmia, from tetanus, from meningeal hæmorrhage, and from cerebral tumours. It enables us, moreover, to diagnose tuberculous meningitis, which is accompanied by lymphocytosis when fully established, and from cerebro-spinal meningitis, which is characterised by polynucleosis, except during the periods of remission. We also meet with cells in the cerebro-spinal fluid when cerebral complications supervene in the course of suppurating otorrhœa, from typhoid fever, from mumps, pneumonia, broncho-pneumonia, etc. Lastly, cells have been met with in the cerebro-spinal fluid in various infectious diseases—infantile paralysis, zona, herpes, etc., etc.

Sub-Acute and Chronic Attacks.

Lumbar puncture, a genuine bioscopy of the meninges, renders great service in the diagnosis of tabes. We are familiar with the protean aspects of this disease, which is apt to run an irregular or abortive course. When we suspect tabes in the victim of syphilis of old standing, and on examination we find evidence of meningeal lymphocytosis, we may unhesitatingly affirm the existence of sclerosis of the posterior columns. This lymphocytosis proves the existence of a meningitis which, far from being the consequence of the parenchymatous lesions of tabes, precedes the latter, and in a sense determines their supervention (Nageotte).

In general paralysis we sometimes meet with lymphocytosis, and this reaction, though inconstant, permits us to distinguish general paralysis from alcoholism, neurasthenia, and brain softening. Should polynucleosis occur, we may suspect the existence of a secondary affection.

An inconstant lypmhocytosis has also been observed in the secondary stage of syphilis parallel with the intensity of the secondary cutaneous symptoms. Syphilitic hemiplegia is also associated with copious lymphocytosis, which distinguishes it from hysterical hemiplegia and the organic forms due to hæmorrhage and softening of the brain. It will be seen from what precedes the valuable assistance that examination of the cerebro-spinal fluid may render in the diagnosis of affections of the nervous system.

But lumbar puncture is also available therapeutically. It is methodically had recourse to in the treatment of cerebro-spinal meningitis. The withdrawal every two or three days of from 5 to 15 cubic centimetres of the purulent liquid surrounding the neuraxis mitigates the symptoms due to cerebro-spinal hypertension, and reduces the meningeal infection. Hot baths, local counter-irritation, and the administration of antispasmodics complete the treatment.

In cases of cerebral tumour lumbar puncture attenuates or relieves the vomiting, headache, and pupillary stasis due to the pressure of the cerebro-spinal fluid in hypertension. In the same way it diminishes the intense headache of the secondary period of syphilis, and Babinski and Boisseau state that it cures urinary incontinence. It was Babinski who, having been induced by observations of voltaic vertigo to practise rhachicentesis in cases of Menière's disease, erected this procedure into a remarkable method of treatment. A single puncture often suffices to quiet all the symptoms, the vertigo disappearing altogether. The noises in the ears are, as a rule, only attenuated, and not abolished, but the symptom on which the operation appears to exert least effect is the deafness.

A Note on the Rôle of

CONSERVATIVE VITAL REACTION IN PATHOLOGICAL ANATOMY,

Particularly in regard to certain Chronic Rheumatoid and Gouty Changes.

By F. PARKES WEBER, M.D., F.R.C.P.,

Physician to the German Hospital, London, and to the Mount Vernon Hospital for Chest Diseases, Hampstead.

It is now generally admitted that the limiting fibrosis about old tuberculous lesions in the lungs and elsewhere, is to be regarded as conservative in nature, but it is not quite so obvious that the same explanation applies likewise to the keloid-like scars resulting from tuberculous glandular abscesses in the neck and elsewhere, and to the scar tissue in ordinary fibro-caseous forms of chronic pulmonary tuberculosis. So also, whilst everyone agrees that the fibrosis about old tertiary syphilitic lesions in the liver is evidence of a conservative vital reaction, many will not readily consent to the view that the fibrosis in all cases of hepatic cirrhosis is likewise of essentially the same nature. (*a*)

In the same way, I believe it is not yet generally admitted that the lipping, synovial overgrowth, and capsular or periarticular fibrous thickening of chronic rheumatoid and gouty joints, and the development of subcutaneous fibrous nodules (with or without tophaceous deposit in them), are essentially manifestations of conservative vital reaction.

In order to make myself clear, I shall first have to explain what I mean by "action" and "vital reaction." The words action, reaction, agent and re-agent are employed in chemistry, physical geography, etc., but in all non-vital processes and phenomena there seems to be very little difference between action and reaction, one reaction serving as, or producing, an agent which provokes another reaction, and so on. Moreover, "vital reactions," which, in the broadest sense of the term, include all those manifestations of irritability which distinguish living from non-living bodies, often (perhaps always) differ from non-vital reactions in being useful (*i.e.*, beneficial for the organism manifesting them), or "conservative" in nature, as if they were purposeful.

In regard to human life and human pathology, I would divide all vital reactions into:—

(1) Mental or voluntary nervous reactions.

(2) Reflex or involuntary nervous reactions.

(3) Vital reactions other than nervous reactions.

Reactions of the third class may manifest themselves (a) by chemical changes, etc., *e.g.*, production of antitoxins, and (b) by anatomical (macroscopic and microscopic) changes. It is only with reactions of this second division of the third class that we are now concerned.

Typical examples of anatomical conservative or compensatory reactions are: (1) the increase of the polymorphonuclear leucocytes in the blood consequent on streptoccocal infections, etc.; (2) the increase of the red blood-cells connected with imperfect oxygenation of the blood in chronic cardiac and pulmonary diseases; (3) growth of skeletal muscles consequent on increased functional activity; (4) myocardial hypertrophy in conditions throwing abnormal work on the whole or a portion of the heart musculature; (5) thickening of the skin and subcutaneous tissue from intermittent pressure or friction; (6) hypertrophy of one kidney after removal or disease of the other kidney; (7) the phenomena of the healing of a wound caused by chemical, physical or mechanical agents, with or without infective (microbic) complications. In all such cases, the "agent" (whether chemical, physical, mechanical or "functional") provoking the reaction, and the conservative or compensatory nature of the reaction are obvious, and no difficulties in teleological interpretation can arise.

Difficulties in interpretation, when they arise, are chiefly due to:—

(1) Uncertainty as to the nature of the morbid agent or agents. For instance, in tuberculous affections, before the tubercle bacillus was discovered by Koch as the exciting cause of tuberculosis, the conservative nature of the fibrosis around chronic lesions could of course be but imperfectly guessed at.

(2) Multiplicity of the agents. For instance, in the case of wounds, the reactive processes necessary for aseptic healing were formerly generally associated with the processes due to the infection of the wound with pathogenic microbes, and before the nature of septic inflammation was thoroughly recognised, the phenomena of healing were necessarily confused with those of reaction towards septic infection.

(3) Confusion between the phenomena of the action with those of the reaction. (*a*) For instance, in chronic tuberculosis, the process of cell-necrosis due to the agent (*i.e.*, to the local presence of the tubercle bacillus) proceeds side by side in the infected animal with reactive attempts at local repair and limitation.

(4) Differences in reaction due to differences of "soil." In human beings, as doubtless in other animals, there are differences in reaction due to individual peculiarity ("idiosyncrasy"), race, sex, age, previous habits, and general nutrition. Children offer a "virgin soil" for the growth of pathogenic microbes. They are infected easily, and the struggle between the morbid agent (the invading microbes) and the infected organism is acute, but usually relatively short. In elderly persons the tissues have, from previous practice, acquired the power of at once resisting many infections, or of yielding less suddenly than the tissues of young persons to certain diseases, such as tuberculosis. It is especially in chronic tuberculosis in adults, where the battle has been very slow and prolonged, that the anatomical results of morbid action are most intimately mingled with the conservative changes due to reaction.

I will now return to the question of the subcutaneous fibrous nodules occasionally met with in rheumatoid conditions in adults. These differ from the well-known "rheumatic" nodules" met with in children suffering from true articular rheumatism, chorea, or rheumatic endocarditis. They are sometimes larger and disappear less readily. The "rheumatic nodules" of children, at least the central portions of the nodules, seem to consist of a more fluid, less organised exudate (*b*), and can, therefore, be more readily absorbed. These differences may, however, be due to differences in re-

---

(*a*) The hypertrophic adenoma-like nodules of the hepatic parenchyma in hob-nail livers are of course to be regarded as an attempt at compensatory over-growth, and are therefore likewise the result of a "conservative" reaction.

(*a*) Cf. F. P. Weber, "A Note on Action and Reaction in Pathology and Therapeutics," "St. Bart's. Hospital Reports," vol. 39 p. 139.

(*b*) See F. J. Poynton and G. F. Still, "The Histology of the Rheumatic Nodule." "Transactions of the Pathological Society," London, 1899, vol. 50, p. 324.

action towards irritation, that is to say, whatever the nature of the local irritation may be (microbes of rheumatism, necrotic foci, etc.), and irrespective of the question whether there are one or several different causes for the irritation, the tissues of adults may react in a more persistent and "fibrous" manner than those of children. The local reaction resulting in the development of the subcutaneous nodules might in both instances be supposed to be "conservative" in nature, that in adults, however, more nearly resembling the local "fibrous" reaction so often seen about chronic tuberculous foci. One might further suppose that many gouty tophaceous nodules are really of the same nature, the only difference being that, owing to some peculiar local or general chemical state, more or less uratic deposit has occurred into the devitalised tissue of the nodule.

It seems to me also that the lipping, synovial overgrowth, and capsular or periarticular fibrous thickening met with in chronic rheumatoid and gouty joints are to be explained in essentially the same way, that is to say, as representing a chronic vital reaction (of a "conservative" nature) towards various more or less unknown sources of local irritation. Amongst the local sources of irritation (probably chiefly microbic or toxæmic), I should certainly include the wearing away of articular cartilages owing to devitalisation from old age (in senile osteo-arthritis) and debilitating illnesses, or owing to relatively excessive use. I would consider wear of the articular surfaces as a "source of local irritation" whenever, by reason of devitalisation or excessive function, it exceeds repair. No doubt, however, the disorderly overgrowth sometimes met with is due to nervous influences, and is analogous to the new-bone-formation which sometimes occurs about and in the neighbourhood of joints in cases of spinal arthropathies (*i.e.*, in tabes and syringomyelia).

OPERATING THEATRES.

PADDINGTON-GREEN CHILDREN'S HOSPITAL.

SINUS THROMBOSIS SECONDARY TO MASTOID ABSCESS.—**MR. ARTHUR EDMUNDS** operated on a child, æt. 5, who had been suffering for several months from a discharge from the right ear. Her adenoids had been removed with a view of relieving this discharge, but this object had not been obtained. Three weeks after the operation for the adenoids the child was admitted with all the signs and symptoms of an acute mastoid abscess. The temperature was especially high, namely, 106.4°, otherwise the case presented nothing of unusual importance. The ear was still discharging, and there was tenderness over the McEwen triangle, but there was no thrombosis or tenderness along the jugular vein. Accordingly, an incision was made behind the ear, the pinna turned forward, and the bone over the mastoid exposed. There are, Mr. Edmunds said, many ways of opening the mastoid. Some surgeons employ a hammer and chisel; others prefer an electrically driven burr; while a third section, apparently a small minority, use a hand gouge. The present operation was practically performed entirely with the latter instrument, which he contended was the simplest and safest method of operating. To perform any bone operation, especially a mastoid, with a gouge, it is necessary for the surgeon to be able to use both hands. The gouge must be of appropriate shape and size, and should be fairly sharp; the best way to obtain such an instrument was to go to the instrument makers and to select a gouge whose handle fits comfortably into the surgeon's palm; the forefinger is laid along the blade of the gouge, which is then cut off level with the tip of the forefinger and re-sharpened. With such an instrument it is possible to perform a complete mastoid operation in about half an hour, and, moreover, to remove all overhanging portions of bone so that the mastoid antrum becomes simply a depression on the side of the head. It is sometimes a little difficult to remove the bridge of bone between the antrum and the middle ear, but this is easily cut through with a couple of strokes of the chisel. The employment of a hammer and chisel very commonly produces concussion, which sometimes lasts two or three days. It is not surprising that this should occur; indeed, it is remarkable that patients are able to stand the prolonged hammering over the side of the head to which they are so commonly subjected during this operation. The electric burr is not, it is true, open to this objection, but all such complicated and elaborate mechanical devices have disadvantages inseparable from their construction. The gouge is held in the hand with the finger pulp resting over its cutting edge; the tip of the finger is laid upon the bone, and, by a sort of rocking movement, the bone is shaved away, the shavings of bone being held between the finger and the tool. The present operation was completed in the usual way, a large flap being cut from the pinna to fill up the upper portion of the bony cavity. All drainage was conducted through the external auditory meatus, the wound behind the ear being completely sutured. The next morning the temperature had fallen to normal, and the general condition of the child was much improved. Towards evening, however, the temperature again rose, and for the next four days oscillated between 100° and 105°. In spite of this, the child remained perfectly comfortable, and took her food well. At the end of this period, it was decided to operate again, and search for further mischief; but on arriving at the hospital prepared to operate, Mr. Edmunds found that the temperature had again sunk to normal, and, moreover, that the pulse, which previously had not followed the temperature, had dropped also much lower than it had been since the operation. Operation was accordingly postponed for another 48 hours, but then, as the temperature had again gone up, it was decided to reopen the wound and remove some more bone. The wound behind the ear was accordingly re-opened, and on shaving away more bone towards the posterior aspect, a small extra dural abscess containing a few drops of pus was opened. This abscess lay between the posterior wall of the antrum and the lateral sinus, and its contents were under considerable pressure. The lateral sinus did not seem to be in any way affected. The abscess was drained behind the ear, and the patient put back to bed. The operation, however, did not improve the child's condition in the very least. The temperature continued to swing as before, but the girl still remained comparatively comfortable. Three days later the jugular vein was tied, and the lateral sinus opened up. There was a small amount of thrombosis in the sinus, and the thrombi were removed until the upper portion of the vein bled freely. Hæmorrhage was then arrested by packing. This operation was again disappointing; the temperature remained as before, but the patient was, if anything, a little weaker, and was becoming distinctly drowsy. There was no optic neuritis and no symptoms of intracranial pressure. The wound was dressed next day under an anæsthetic, and from this time onwards the child's strength began to fail. The next day slight optic neuritis was noticed, and shortly after this the eye on the affected side became slightly prominent. A diagnosis of thrombosis of the cavernous sinus was then made, and it was decided that the case was beyond further operative treatment. The symptoms progressed, and the child died about 48 hours later.

At the post-mortem it was found that thrombosis had extended very little from the lateral sinus on the affected side, but that there was thrombosis of both cavernous sinuses, which had affected the opposite lateral sinus; moreover, there was an area of the petrosal sinus on the affected side which was quite free from clots. There was no cerebral abscess. Mr. Edmunds said it was quite obvious in this case that the spread from the mastoid antrum was not due to any gross defect in the bony capsule of the ear, the organisms passing by lymphatic structures and by the small communicating veins, so that in all probability infection of the cavernous and other sinuses was present from the commencement. This theory explained the fact that, although at each operation pus was definitely found and evacuated, none of the operations afforded any relief to the patient.

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

Palmar Aneurysm.—**Mr. Newbolt** operated upon a case of palmar aneurysm in a male, æt. 32, who had noticed a swelling in the centre of the palm of his left hand for two months. This swelling was spherical, and about an inch in diameter, and had followed the wound caused by a chisel. On examination it was bluish in colour, and of elastic consistency, reducible on deep pressure, but filling rapidly when the pressure was released. Pulsation could only be stopped by compression of both radial and ulnar arteries. The veins of the hand and arm were not distended. There were pain and numbness of both index and middle fingers. Under ether, a tourniquet having been applied, a longitudinal incision was made over the swelling, the skin, palmaris brevis, and palmar fascia, were divided, and the sac was exposed. It was opened, a black, non-adherent clot turned out, and the sac wall dissected away from the superficial tendons and digital nerves. Three arteries were tied—*i.e.*, the superficialis volæ, the ulnar, and a communication with the deep arch. The wound was closed with deep sutures and silkworm gut. It healed soundly, and early movement of the fingers was practised. One month after operation movement of the fingers is perfect, but there is still some numbness of the two fingers at first involved. Mr. Newbolt said that these aneurysms were very rare —it was the only one he had seen in a surgical experience of 24 years. He considered that the best treatment was to deal directly, if possible, with the sac, and not to tie the ulnar and radial or ulnar alone above the wrist. Though the latter methods were efficacious, yet they occasionally left a hard matted nodule, which interfered with the free use of the flexor tendons or involved the digital nerves. The sac was formed by the matting of the surrounding tissues with the tendon sheaths and digital nerves. It was necessary to dissect the latter out very carefully, and for this purpose the use of the tourniquet to render the parts bloodless was essential. Considering how commonly the palm of the hand was wounded, it was surprising that aneurisms did not occur more frequently. In this case, in all probability, the vessel was only partially severed at the time of the accident. As the patient wished to be cured as speedily as possible, other methods of treatment, such as direct pressure, were not considered.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Obstetrical and Gynæcological Section.

Meeting held Thursday, January 9th, 1908.

The President, Dr. **Herbert Spencer**, in the Chair.

Dr. Herbert Williamson read a short communication on a case of enucleation, during the seventh month of pregnancy, of a uterine fibro-myoma weighing 17½ lbs., which was followed by premature labour two days later. The patient was a primigravida, æt. 32. When four months pregnant she suffered from repeated attacks of acute abdominal pain, and became emaciated with some fever and the distension of the abdomen was so great that she was unable to lie down in bed. At the time of the operation the tumour, which could be felt distinct from the gravid uterus, was thought to be a malignant growth of the ovary, but it was found to be a uterine fibro-myoma undergoing necrotic degeneration. The area of attachment of the tumour to the uterus was rather narrow, but required enucleation. A premature child was expelled three days later, but the patient made an uninterrupted recovery.

Norman C. Carver, M.B., and **John S. Fairbairn**, M.B., read a case of

HÆMORRHAGE INTO THE PONS VAROLII AS THE IMMEDIATE CAUSE OF DEATH IN THE ECLAMPSIA OF PREGNANCY, WITH ILLUSTRATIVE CASES.

The authors record the case of a primigravida, æt. 24, who, after exhibiting signs of impending eclampsia, was found unconscious and straightway admitted to hospital. In view of the history of the illness and the presence of œdema and a high degree of albuminuria, the case was thought to be one of eclampsia, and, as the patient was in a state of deep coma, with Cheyne-Stokes respiration, rapid dilatation of the cervix was done, followed by the extraction of a fœtus of between five and six months development. The patient died a few hours later, and at the autopsy death was found to be due to an extensive hæmorrhage into the pons varolii. The authors argue that although the immediate cause of death was a pontine hæmorrhage, the case was primarily one of eclampsia, and in support of this quote four recorded cases of a similar nature, in which an unsuspected cerebral hæmorrhage was found post-mortem. Details of these cases are given, and, from an analysis of the symptoms presented by them and the authors' case, attention is drawn to such features in them as may serve to arouse a suspicion of the occurrence of apoplexy in the course of an eclamptic attack. These are, briefly, deep coma, and cyanosis, with marked respiratory disturbance, occurring in a young patient presenting the urinary and other signs of eclampsia, and they are especially suggestive when the attack is unaccompanied by the usual eclamptic convulsions.

The **President** (Dr. Herbert Spencer) thanked the authors for the interesting paper. He had not met with a case of hæmorrhage into the pons varolii in eclampsia, but he could recall two cases of hæmorrhage into the substance of the brain, one observed at a post-mortem examination and the other in which hemiplegia occurred, from which the patient slowly recovered. He thought that apoplexy was a well-known cause of death in eclampsia, and was surprised that the authors had not found more cases recorded, although they did not claim that their paper was exhaustive. In view of the possibility of the occurrence of cerebral hæmorrhage in eclampsia, the intravenous injection of a large quantity of saline fluid would appear to be not unattended with risk.

Dr. **Macnaughton-Jones** recalled the fact that the "apoplectiform" was one of the old writers' division of eclampsia, and in which sanguineous and serous effusion occurred into the ventricles. The symptoms were such as described in this case. He dwelt on the importance of early anticipation of the eclampsia, especially through the ocular symptoms and signs which were often present, and in which an ophthalmoscopic examination afforded most valuable evidence of the approaching danger. One of the most valuable therapeutical means they possessed to control the increased blood pressure in these cases of threatening cerebral hæmorrhage he believed to be the employment of weak doses of pilocarpin, which was also useful in checking the convulsions. If necessary, its full physiological action might be neutralised by 1-100th of a grain of atropin. He had known eclampsia ending fatally occur as early as the fourth month of pregnancy.

Mr. A. **Lionel Smith** said he had seen three cases of cerebral hæmorrhage complicating eclampsia or toxæmia of pregnancy, in all of which the diagnosis was confirmed at the necropsy. In one of them the hæmorrhage occurred in association with eclamptic convulsions after delivery, but in the other two the patients were not in labour, and had only reached about the 30th week of pregnancy.

Dr. **Amand Routh** had not had an opportunity of seeing a post-mortem examination of any case dying of puerperal eclampsia where cerebral hæmorrhage had been found, but thought the authors had shown how often such hæmorrhage might supervene and be the immediate cause of death. He thought it unwise to increase arterial tension, as must have been done in the first case reported, when 10 oz. of blood were removed, and 40 oz. of saline infusion injected. This may well have increased the tendency to hæmorrhage. He presumed that saline infusion in these cases is given to dilute the toxines at each given point, and to increase the leucocytosis to combat the toxines; but it was doubtful if it should be given when it increased arterial pressure. On the other hand, he considered that the suggestion to give pilocarpin (at all events in the doses usually prescribed—viz., 1-5th gr.) was fraught with grave danger. He considered it should never be given in cases where apoplectic symptoms, or coma, was present, for he had seen patients under its influence suffocated by the enormous quantity of ropy mucus secreted by their salivary and broncho-pharyngeal glands. He was interested in the fact that epigastric pain had been mentioned as a precursor of eclampsia in some of these cases of albuminuria of pregnancy. He considered this sign, following ocular evidences of high arterial tension, increasing albuminuria, and diminishing excretion of urea, a valuable indication that eclampsia was impending, and that steps should be taken to induce labour without needless delay.

Dr. D. C. **Rayner** referred to a case of eclampsia under his care, in which a fatal termination was due to cerebral hæmorrhage. The patient was in the eighth month of her third pregnancy when convulsions set in. They were frequent, and seemed more marked on the right side. The pupils were also noticed to be unequal. The urine contained albumen, and the patient was not in labour. Coma deepened, and the patient died in a few hours. There was extensive hæmorrhage into the right corpus striatum and optic thalamus.

Dr. R. H. **Hodgson** said that he thought the lesson to be learnt from this instructive paper was, in all cases of eclampsia in pregnant women, empty the uterus. He had done so in six cases he had, and in all the women recovered, five very rapidly, and one in whom some slight convulsions continued for five days, was quite well after one injection of pilocarpin. Emptying the uterus causes the blood to flow to the portal system, and thus lessens the danger of cerebral hæmorrhage. He did not understand the object of the saline injection.

Dr. **Fairbairn**, in reply, said no attempt had been made to make an exhaustive collection of cases of apoplexy as the cause of death in eclampsia, and the cases collected were those of hæmorrhage into the pons or base of the brain without unilateral symptoms to suggest apoplexy. Large cerebral hæmorrhages were not frequent in eclampsia, as was shown by the statistics quoted in the paper. The cases recorded were undoubtedly rare, but the possibility of a deeply comatose and cyanosed eclamptic patient having also a cerebral hæmorrhage ought not to be lost sight of, especially in giving a prognosis.

The following specimens were shown:—

Dr. J. P. Hedley:—(1) Hydrosalpinx with torsion of the pedicle; (2) double hæmorrhagic cysts of ovaries.

Dr. Harold Sington:—Tumour of the fœtal head.

Dr. Lewers:—Cancer of the cervix (advanced); hysterectomy by Wertheim's method.

Alderman J. Rubie, Chairman, presided at the recent fortnightly meeting of the Bath Sanitary Committee held at the Guildhall on Monday. The Midwives Sub-Committee's recommendation was adopted as regards the appointment of Miss Hilda Lea as Lady Health Visitor, to act under the direction of the Medical Officer of Health, and generally to assist him in his duties, under the Midwives Act, 1902, and in preventing infantile mortality, in accordance with the schedule of duties already approved.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Pathology.

Meeting held Friday, January 10th, 1908.

The President, A. R. **Parsons**, M.D., in the Chair.

SEPTIC ENDOCARDITIS.

Dr. **Bewley** said the case was one of a young man born in 1885. In 1898 he had suffered from rheumatic fever, being laid up for six months, and his heart being, he believed, then affected. During the following three years he had further attacks. He came into hospital in February, 1905, suffering from breathlessness and palpitation. He was found to have a hypertrophied heart, double aortic disease, and mitral regurgitation. During the time the patient was under his care he never suffered from fever; the main clinical feature was the regurgitation. About the middle of October last he came to see him (Dr. Bewley), looking very ill, his heart beating 130 to 140 per minute. He was admitted to hospital on October 19th, and died on December 16th. His last illness had begun in the previous June with feverishness, occasional sweatings, and loss of strength. While in hospital his evening temperature ran to 101° and 102°, and his morning temperature varied from normal to 100°. The condition of the heart was much the same as before, and sometimes a presystolic thrill was felt. He had also a slight hemiplegic seizure, from which he recovered in a few days. The diagnosis was septic endocarditis. About the middle of November a tender spot came on one side of his head. For four or five days it was swollen, and gradually subsided. The temporal artery might be felt as far as the spot, but could not be traced beyond it. No abscess occurred, showing that the infection was very mild. The same symptoms occurred on the other side at the same spot. At the post-mortem the heart was found very much enlarged, and the pericardium was found to be universally adherent—a condition of which there was no clinical sign whatever. The right cavities of the heart were comparatively small, the left ventricle was enormous, and both the mitral and aortic valves were festooned with soft pink vegetations. The kidneys were enlarged; the spleen was very much enlarged, and there was an abscess in connection with an infarct in the spleen. Dr. Harvey made an examination of one of the vegetations, which showed enormous numbers of cocci of the streptococcus type. The case, then, was one of endocarditis, with an organism of extremely mild virulence; the sepsis had lasted fully six months.

The **Secretary** said that, considering no cultures had been made, it was difficult to tell from the section alone whether they were dealing with streptococci. He believed they were not streptococci, but were rather diplococci of the pneumococcus type.

The **President** asked Dr. Bewley if he thought the final attack was a separate and distinct infection, or did he consider that the patient was carrying the organisms in his system all the time, and they simply found a suitable opportunity to develop?

Dr. **Bewley**, in reply, said it seemed to him that the final infection was a distinct and new one, but, of course, he could not prove it to be so.

Dr. **Harvey** mentioned that he looked on the cocci as streptococci.

INTRA-THORACIC TUMOUR.

Dr. **Travers Smith** gave the main clinical facts of the case, of which Dr. Earl would show post-mortem specimens. The patient, a man, æt. 56, was admitted to hospital on April 23rd, 1907, and died in about six weeks. A few months before admission he received a heavy blow on the chest, but one could not say how much that had to do with the growth in his thorax and its extreme distribution. About two months before admission he noticed a swelling, which extended into his right arm and right side of his chest. About four weeks previously he noticed the veins of his chest getting prominent, and his right ear getting rather blue. On examination he found his right arm and neck, especially on the right side, œdematous, and not pitting on pressure. The enlargement of the veins of the chest on the right side did not extend below the thoracic margin. They came to the conclusion that there was something obstructing the blood return through the right innominate vein, and, perhaps, to a less degree, through the left, and that the obstruction was due to pressure from an intra-thoracic tumour. In about a week the same symptoms appeared on his left side. An effusion in the patient's right pleural sac accumulated rapidly, and on tapping it they found it had the character of a passive effusion, with poverty of albumen and cellular elements. He had to be tapped several times. Cyanosis was now very remarkable, and he began to breathe with a slight stridor. About a week before his death he became very œdematous in his lower extremities, and some fluid formed in the peritoneum. Examination of his heart and pulse prevented attributing the condition to general cardiac weakness. One day the patient complained of violent pain in his right axilla, and they concluded that a vein had burst. He was given a small hypodermic of morphia to relieve the pain, and died six or seven hours afterwards from respiratory embarrassment.

Dr. **Earl**, in exhibiting the post-morten specimen, said the tumour involved all the structures in the thorax. The whole of the superior vena cava was absolutely filled with it, and it grew high up and into the innominate vein. It projected into the right auricle of the heart, and filled it up, and projected into the ventricle. There were no growths elsewhere, and the tumour had the structure of a lympho-sarcoma.

INTRA-THORACIC LYMPHO-SARCOMA.

Dr. **Earl** exhibited a second specimen of extensive lympho-sarcoma in the upper parts of the thorax, but lying more in front of the structures than surrounding them. It grew down on to the pericardium, and the heart was covered all over with a thick layer of tumour. It extended to the left pleura, and from it into the lung. There were also several globular secondary growths in the liver of the same structure.

AORTIC ANEURYSM.

Dr. **Boxwell** exhibited a specimen taken from a male, æt. 33. He was admitted to the Meath Hospital on October 11th, 1907, with a provisional diagnosis of "paroxysmal asthma," with, possibly, "pneumonia." When seen, the patient was sitting up in bed. The face was livid, his head drooped between his shoulders, suffering from violent dyspnœa, and streaming with perspiration. The larynx was evidently obstructed above, and the loud stridor at the root of the neck pointed also to obstruction in this region. The pupils were regular. There was no œdema of the upper extremity, and the pulses, though extremely feeble, showed no perceptible difference. There was, however, a patch of dulness under the right sterno-clavicular articulation, and a heaving pulsation palpable just above this point at the root of the neck. *Diagnosis:* Innominate aneurysm. The relief given by morphia and amyl-nitrite was short-lived, and the patient died on the morning of October 13th, 1907. At the post-mortem examination, the aorta was found to be the seat of a saccular aneurysm, the size of a duck's egg. The innominate artery was involved in the aneurysm, while the left carotid and subclavian opened directly into the sac. The aneurysm lay directly under the right sterno-clavicular articulation, and caused a partial dislocation of the joint. The sac was crossed in front by the left innominate vein, which was incorporated in its wall, and nearly obliterated, its function having been taken on by an enlarged left superior intercostal. Both recurrent nerves must have been subjected to considerable pressure, as were also the trachea and œsophagus.

ANEURYSMS OF AORTA.

Dr. **Earl** showed (1) an aneurysm of the aorta. It was situated about the junction of the descending part of the arch, with the thoracic aorta, and was about one and a half inches in diameter. It projected to the left side, and was adherent to the periosteum of the vertebræ, and to the œsophagus, which it had flattened out somewhat. It also pressed on the left side of the trachea, and slightly flattened it. Its opening into the aorta was about ¾ in. in diameter. The aneurysm was almost filled by a firm clot. It was taken from the body of a man, æt. 40, who died of tuberculosis of the lungs. He had had syphilis 16 years before his death. The aorta was atheromatous, but not dilated.

(2) An aneurysm in same position with a wide opening into the aorta. The aorta was considerably dilated and atheromatous.

The wall of the aneurysm was adherent to the periosteum of the vertebræ and to the œsophagus. The part adherent to the œsophagus was deeply ulcerated, so that one ulcer had gone right through the wall, and had affected the muscular coat of the œsophagus.

BLOOD SLIDES SHOWING MARKED EOSINOPHILIA.

Dr. **Earl** said the blood was from a gentleman returned from somewhere on the West Coast of Africa. There was a strong suspicion that he had malarial disease. He was struck with the number of coarse granular cells in the blood. He selected a thick part of the film in order to get a good many leucocytes, and in the field there were three eosinophile cells and some of polynuclear and neutrophile cells. The condition was not very uncommon, but was more particularly noticed in cases of worms of different sorts, though it occurred in other conditions.

Dr. **Moorhead** said he had a case of simple endocarditis with rheumatic endocarditis, and every attack of rheumatism was accompanied by eosinophilia. He thought at first that there was some intestinal infection, but had not been able to detect any.

The **President** recalled a communicaion which he had made to the Medical Section of the Academy on two cases of enormous enlargement of the spleen, accompanied by marked eosinophilia.

Dr. **Earl** replied.

TWO CASES OF POISONING BY CRUDE PHENOL.

Dr. **Boxwell** showed two specimens. Case I.—Stomach and spleen of a girl, æt. 15, who was poisoned by drinking four ounces of crude carbolic. She was dead when brought to hospital, and the post-mortem was made about 24 hours after, no attempt having been made to counteract the poison. *Naked eye appearance.*—Stomach of leathery consistence; serous surface dull, and of a bright cherry-red colour. The same appearances were noticeable on the contiguous surface of the spleen. The mucosa of the stomach and œsophagus was hard and brittle, dull greyish-white in colour, with whiter points, resembling incrustations, as if roughly painted with white lead. There was no evidence of this necrosis on the tongue or fauces, although in the latter an œdematous condition of the mucous membrane was very remarkable. Case II.—Viscera, including tongue, pharynx and œsophagus, of a child, æt. 12 months, poisoned with crude phenol. In this case the amount of acid swallowed could not be accurately ascertained. The child was made to take a good drink of it, but was still alive when removed to hospital. The points emphasised here were:—(1) That about four ounces of whiskey were administered within a few minutes of the dose of acid, followed by a copious irrigation with whiskey and water. There was no other antidote used. And (2) whereas enough had been already absorbed to produce a fatal depression of the heart's action, the amount of coagulation necrosis was not great, the stomach bearing a marked contrast to that of the previous case. The condition of the pharynx and œsophagus in the two cases was much the same. Some details of a third case were also given, where a woman, æt. 27, had swallowed eight ounces of the crude acid. She also was treated with whiskey, whiskey and water, and glycerine and water given through a stomach tube. A considerable quantity of brown fluid smelling strongly of carbolic acid was syphoned off with the initial dose of whiskey, and, as a result of the treatment, the woman is doing well. It is a remarkable fact that within a few minutes of the administration of whiskey she recovered consciousness, and within an hour was vomiting naturally.

ROUND WORM IN LARYNX AND TRACHEA.

The **Secretary** exhibited an old museum specimen with a round worm doubled up in the trachea and larynx of a child.

The new wing which has been added to Stanley Hospital was formally opened on January 13th by Lord Derby.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

Meeting held January 17th, 1908.

The President, Dr. Walker Downie, in the Chair.

Dr. Alexander MacLennan showed two cases of "Congenital Dislocation of the Patella." The patients were sisters, and they had a brother who was the subject of a congenital dislocation of the hip. In the elder girl the dislocation affected both patellæ, but in the younger girl the deformity was unilateral. A skiagram of the elder girl's lower limbs showed the abnormal position of the patellæ and their relations with the bones entering into the formation of the knee-joint. In all cases the patella was displaced outwards, and caused considerable lameness. The occurrence of congenital dislocation in three members of the same family is interesting.

Dr. MacLennan hoped to show these cases after treatment had been carried out. This consists of an operation, the essential part of which is splitting the insertion of the semi-membranous muscle and attaching a part of this to the inner side of the patella. This he has found a very satisfactory method of getting rid of the deformity, and increasing the usefulness of the limb.

Dr. W. S. Syme showed a boy who had undergone the "Radical Mastoid Operation," and described the case. This was remarkable for the absence of pain and other symptoms till a very short time before operation was thought necessary. There was suppuration of the middle ear, which lead to thrombosis of the lateral sinus. Both of these conditions were treated, but their result was not satisfactory till the internal jugular vein was subsequently tied, and the contents of the lateral sinus again evacuated and the wound drained. The success attending this procedure has been very marked. Partial facial paralysis followed the operation, and is not yet recovered from; while optic neuritis, which accompanied the acute condition, is now passing off.

Dr. Syme then showed two cases in which he had operated for "Disease of the Frontal Sinus," and gave a description of the various methods employed in the treatment of the various accessory nasal sinuses. He laid emphasis on the importance of exhausting all intra-nasal methods of treatment before resorting to an external operation. The patients shown demonstrated the fact that the deformity resulting from the falling in of the anterior wall of the frontal sinus can be almost entirely removed by the injection of paraffin.

Another case was referred to by Dr. Syme, in which he removed the stump of a tooth from the maxillary antrum. Six years previously an attempt had been made to extract the tooth when the crown was broken off. The stump was presumably subsequently pushed into the antrum during efforts to remove the stump, which was supposed to be extracted as it had disappeared from the alveolus. After this time it lead to the symptoms which caused the patient to seek relief.

Dr. G. Burnside Buchanan read notes of a case of "Injury to the Motor Area of the Brain." The injury was caused by a block of wood, one square foot in thickness and three feet in length, falling on a dockyard worker's head. The result of this was a compound, depressed, and comminuted fracture of the skull in the region covering the right fissure of Rolando. The wound was cleansed, splinters of bone removed, and a considerable portion of the brain substance of the motor area destroyed. The recovery of the patient from the immediate effects of the operation was good; but the resulting paralysis of the left side shows no sign of improvement. The interest of this case centred round several conditions such as the absence of suppuration during the healing of the wound; the slight amount of damage to the patient's general condition caused by the loss of a large amount of brain substance. There is also an entire absence of Jacksonian epilepsy, though this condition usually does not supervene till the scar of the wound is old and much contracted. Dr. Buchanan pointed out that in spite of this the prognosis in such cases is not favourable, his patient being bedridden, suffering from insomnia, and the mental condition not so good as when the injury was recovered from.

Dr. A. N. MacGregor described a

NEW METHOD OF DETERMINING AND RECORDING THE EFFICIENT OUTFLOW OF URINE IN CASES OF STRICTURE OF THE URETHRA,

and exhibited by means of lantern slides several comparative charts of illustrative cases. Dr. MacGregor gave an account of the circumstances which led him to adopt this means of learning the condition of a stricture of the urethra. He showed that the condition of a stricture can be recorded graphically upon a chart by indicating the efficiency of the urethra as a channel for the passage of urine from the bladder. He then described the method, which is briefly thus:—The patient is provided with a watch, by which he can measure time in seconds, a glass vessel graduated in drachms for measuring the quantity of urine; and a chart ruled with vertical and horizontal lines like a clinical chart. The vertical lines divide the chart into periods of time, months, weeks, and days, which are counted from left to right. Horizontal lines represent drachms of urine passed in periods of five seconds, and the numbers increase from a zero line upwards from 1 to 30. The patient, while micturating without any special effort, allows the urine during a period of five seconds to fall into the graduated vessel. The number of drachms is then recorded, with the date of the observation, by placing a dot in the proper square on the chart. A line joining the dots thus made gives a graphic record of the efficiency of the urethra as a channel for the passage of urine during the time in which observations are made in this manner. Dr. MacGregor, when showing some charts that had been made in this way, expressed the opinion that this method had a greater amount of practical utility than any or all of the mechanical means at our disposal for the measurement of the patency of the urethra in cases of stricture, as the chart showed the effect of passing bougies through the stricture, and indicated the size of these instruments, and the frequency with which they should be used.

CENTRAL MIDWIVES BOARD.

Meeting held Thursday, January 16th.

The President, Dr. Champneys, in the Chair.

TRAINING SCHOOLS.—THE COOMBE HOSPITAL.

A deputation from the guardians and directors of the Coombe Hospital, consisting of Dr. M. J. Gibson, the Master, Mr. W. H. F. Verschoyle, a member of the Board of the Hospital, and Mr. G. Perry, the Honorary Secretary, attended and presented a memorial praying the Board to rescind its resolution of December 19th removing the name of the Coombe Hospital from the list of recognised training schools. The memorial was supported by letters from the Very Rev. Canon Scally, P.P., the Rev. J. D. Smylie, and Sir Charles A. Cameron, Medical Officer of Health for the City of Dublin, and by a statutory declaration made by the Registrar of the Coombe Hospital as to the circumstances under which the Board of the hospital first learned of the correspondence between the Secretary, Dr. Stevens, and the Registrar on December 30th.

The members of the deputation severally addressed the Board in support of the memorial.

Dr. M. J. Gibson made application in due form for approval as a teacher.

The deputation then withdrew and the Committee deliberated.

Having fully considered all the evidence and arguments submitted to them by the deputation, the Committee took no action on the memorial, but recommended that Dr. Gibson be approved as a teacher. This was carried.

Letters were read from Dr. Stevens, late Master of the Coombe Hospital, Dublin, and from Messrs. D. and T. Fitzgerald, his solicitors, asking the Board to reconsider its decision not to accept any certificate signed by him in future. The Board, however, declined to reconsider its decision.

A letter was read from the Registrar of the General Medical Council asking whether it was the intention of the Board to take proceedings under Section 12 of the Midwives Act against Dr. Stevens and Miss Myerscough. The recommendation of the Committee was adopted that the General Medical Council be informed that the Board does not contemplate taking proceedings in the above cases.

A letter was read from Dr. W. Arnold Evans, Medical Officer of Health for Bradford, as to advertising by midwives. It was agreed that Dr. Evans be informed that the Board has no power to prohibit advertising by midwives.

The names of four women were removed from the roll on the grounds of old age, ill-health, or inability to comply with the rules. Mildred M. Burgess, M.D., and W. Cunliffe, L.R.C.P., L.R.C.S., were approved as teachers.

A motion down on the agenda referring to the payment of fees to medical men was postponed, as Mr. Ward Cousins, who was to have proposed it, was absent on account of illness.

The Secretary's report of the December examination showed that a total number of 213 candidates entered, of whom 179 passed, the percentage of failures being considerably less than heretofore. The number of those intending to practice as midwives was 106, showing an increase in this division.

The financial report contained a statement from Mr. Fordham that the balance in hand was sufficient to cover the present year; but the Committee, after full deliberation, had come to the conclusion that, owing to the failure of many of the County or Borough Councils to comply with the rules of the Act, the present condition of affairs was unworkable and impossible to continue. It was decided to report this matter to the Privy Council, giving a list of the defaulters.

The date of the next meeting was fixed for February 13th.

CORRESPONDENCE

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Jan. 19th, 1908.

Serum Therapy.

Serum therapy in its various applications is destined to play an important rôle in the modern treatment of disease. The different saline solutions representing physiological serum, anti-diphtheritic, tetanic, streptococcic serums have long entered common practice, while that of Quinton or marine serum lays claim to be a panacea for many affections, although of dissimilar natures; eczema, varicose ulcers, psoriasis, enteritis, constipation troubles of the menopause, and tuberculosis (?).

Dr. Quinton has formulated precise rules that should govern the employ of his serum, and which may be of interest to mention.

In the first instance, the doses should not be too large as a too active reaction might follow, which, although without danger, might fatigue the patient uselessly. On the other hand if the dose was too small, the marine plasma would have no appreciable effect.

The injection should be repeated at least twice a week, and in some cases three times a week.

The dose employed for adults in every affection, except for eczema, is generally from one ounce and a half to three ounces. The first four injections, at the rate of three a week, should be of the smaller dose, and ten succeeding injections of the full dose given twice a week.

In *eczema* the dose for adults should never exceed one ounce, twice a week. Improvement is generally immediate (decrease of the itching, secretion, etc.). If after two or three injections no improvement is observed, the injections should be made three times a week or every two days.

For varicose ulcers accompanied with eczema the dose should be the same as for eczema, but in simple ulcers from one and a half to three ounces might be injected. The same may be said of psoriasis.

In all other affections: Muco-membranous enteritis, inveterate constipation, pulmonary tuberculosis, osseous and cutaneous, dysmenorrhœa, chlorosis, lymphatism, etc., the first four injections should be always of one ounce and a half, and afterwards increased to the maximum dose.

In infantile gastro-enteritis, the doses should not exceed one ounce every three days, except in very grave cases, when the injections should be repeated every two days.

In eczema of children, the dose should never exceed two drachms, repeated every two or three days.

The first injections of marine plasma may provoke a passing reaction manifested by either a great prostration or, on the contrary, by a period of excitation with a rise in the temperature; the phenomenon lasts a few hours. Far from being a cause of uneasiness a favourable prognosis should be drawn from this reaction. If, however, the reaction was too intense, it proved that the proper dose had been exceeded, and less should be given the next time.

As to the duration of the treatment, M. Quinton says that although the effect is immediate in many cases, especially in eczema and infantile gastro-enteritis, yet in order to effect a permanent cure from 12 to 15 injections should be given. In chronic affections, such as tuberculosis, there is no limit to the treatment. A series of 20 injections should be made, and the treatment interrupted during a month, when a new series might be repeated.

Paratoxine.

MM. Gérard and Lemoine, of Lille, made a communication at a recent meeting of the Académie de Médecine on a substance obtained by the action of ether of petroleum on the liver and the bile, to which they gave the name of paratoxine. Having made experiments on animals, they tried on man, and it seemed to them to possess a controlling action on tuberculous disease.

The results of nearly 300 cases were so favourable and so constant that they warranted publication.

We administer, they said, paratoxine in subcutaneous and intra-laryngeal injections, or by the mouth. The average dose is one cubic centimetre, but it might, if needs be, be increased to three or four cubic centimetres.

By the mouth the paratoxine is given either in the natural state, or in pills. From 5 to 20 cubic centimetres daily may be given in urgent cases, such as profuse diarrhœa, with rapid results. The treatment by injection should be continued until the appetite was improved, weight regained and improvement in the physical signs was observed, that is to say, from two to three months.

Intra-laryngeal injections are indicated in tuberculous laryngitis at the dose of from two to five cubic centimetres, repeated every day or every two days.

Under the influence of the treatment the pain of deglutition disappears, the voice recovers its tonicity, and the ulcerations heal.

The general effects of paratoxine in the treatment of pulmonary consumption might be resumed as follows: Improvement in the general condition, the patient feels better, the appetite increases considerably as well as the weight of the patient; dyspnœa diminishes and frequently disappears, strength returns to a certain extent, while the cough, as well as the expectoration, becomes more rare and the temperature diminishes gradually, while the bacilli decrease in number in the expectoration. Patients in the third stage of the malady, however, derive no benefit from the treatment.

GERMANY.

Berlin, Jan. 19th, 1908.

At the Verein für Innere Medizin, Hr. v. Leyden communicated a note on

Hemisystole.

He had already, he said, published a number of observations on hemisystole, or, as he had called it in his earlier publications, non-simultaneous contractions of the two ventricles. The first case occurred in 1868. A lady of middle age suffered from cardiac mischief, and showed the above-named peculiarities. Before this she had suffered from acute rheumatism; there was then considerable cardiac hypertrophy, with systolic murmurs. The apical impulse was double, with a short distance between the two (the one a little farther out than the other). By auscultation a systolic murmur, a diastolic sound, and a systolic murmur were heard; with two contractions there was but one cardiac impulse and one pulse beat at the radius. From this the speaker concluded that the contractions of the two ventricles were not synchronous. The profession scarcely took notice of these observations at the time. In 1875 the speaker published two similar cases (Virchow's Archiv., Bd. 65), on one of which an autopsy was performed. There was considerable insufficiency of the mitral valve and excessive dilatation of both auricles. These cases also failed to obtain recognition at the hands of the profession. Fraentzel characterised the condition as "bigeminy," and Riegel followed him. Traube had seen the phenomenon several times, and also in animals who were dying. These observations did not fit V. Leyden's cases which were under observation for lengthened periods. The term "bigeminy" was simply a naming of the condition, and did not express any diagnosis of the cause. A discussion took place on the subject in that Society in 1903. Not long ago the speaker was in a position to publish a similar case which he had had under observation for over a year, and which he had examined repeatedly. It was the case of a man of about 30 years of age who came to the clinic in May, 1906, with cardiac symptoms. He had formerly suffered from acute rheumatism, and for some years some mitral insufficiency had been known to exist. The patient now lay almost altogether in bed, was difficult to move, had a good deal of dyspnœa, but neither cyanosis nor dropsy. There was very extensive cardiac dulness over the anterior thoracic wall that occupied almost all the other thoracic space. The other symptoms were not very pronounced; the urine was normal; the pulse normal, between 77-80. If the hand was placed over the cardiac region, however, a quick impulse was felt. Auscultation gave a re-duplication of the systolic sound, but the radial pulse responded to the first one only. By Röntgen illumination the form of the heart was seen to correspond to that shown by percussion. Diagnosis: mitral disease, from the systolic murmur and its relation to hemisystole, like the previous cases. The patient became gradually weaker; gastric spasms appeared, with much nausea and occasional vomiting. The speaker believed the vomiting to be due to compression of the œsophagus. Death took place in February last. The autopsy showed very considerable enlargement of the heart, considerable dilatation of the mitral orifice, so that it allowed the passage of several fingers; the mitral valves were contracted and hard. The aortic valves were sound, the left ventricle but little, the right ventricle and right auricle, on the other hand, very much dilated. As regarded the significance of the condition, the unusual degree of mitral insufficiency must be looked on as the cause, along with the excessive dilatation of the mitral orifice. The whole process must be looked on as a sort of compensating arrangement. With every systole, when there was mitral insufficiency, a backward wave was started in the pulmonary artery, and the right ventricle could not be completely emptied. At the succeeding diastole the right ventricle was immediately refilled and excited to a new contraction at a time when the left ventricle, on account of the exaggerated tension in the pulmonary region, was not yet quite filled. This, therefore, did not yet take part in the second contraction. The second contraction of the right ventricle was, however, more effective, and made up by a repeated contraction for the extra work thrown on it by the left.

The speaker then passed on to discuss the origin of systole. According to some authors, it had a myogenic origin. Engelmann had pronounced in favour of this view. According to this, the muscles of the heart did not contain any nerves, but they were excited to contraction from the auricle. According to other authors, nerves had been seen in the cardiac muscles and also ganglionic cells as centres for contraction. It was a matter of indifference whether the blood pressure in the ventricles acted on the muscles or the nerves.

AUSTRIA.

Vienna, Jan. 19th, 1908.

Pressure Treatment in Urology.

Kornfeld exhibited an instrument he has devised for the treatment of enlarged prostate, constriction in rectum, stricture in urethra, and effusions in perimetritis. The instrument is of a heart shape or fiddle form, "Kolpeurynter." The manner of using it in the rectum is to insert it like a pessary, and then fill it with air, water, or mercury, according to the resistance required. For an enlarged prostate a vibratory or shock movement can be obtained by applying greater force on the syringe. When used for a stricture a catheter is first inserted and allowed to remain two or three minutes and then withdrawn, and the instrument applied with a fine sound. After being placed in the required position, the air, water, or mercury is pressed into the fine "Kolpeurynter" and caught with a screw or clamp, which maintains the pressure. This pressure is kept up for ten or twenty minutes before it is released, which often leaves a free channel the next day. In cases of enuresis nocturna, Kornfeld has obtained excellent results in six cases on whom he had used the instrument. The treatment was simply mechanical. Care should be taken that too much shock should not be given, as it has a powerful effect on the system when carelessly applied. Frankl asked how the patient should lie when the "Kolpeurynter" was applied per rectum. If the patient were on the back, the pressure of the mercury would be downwards, and therefore not on the prostate. With this object in view it would be better if the patient lay on his face. Halben was of opinion that in cases of exudation from perimetritis the patient should not lie on her back, but on that side of the pelvis in which the exudation lay. Foges believed this distension was highly satisfactory in rectal strictures, and had used a similar instrument called a pneumatic proptoscope with great advantage.

Kornfeld replied that his method of using the instrument in prostatitis and perimetritis was to put the patient on the knees and elbows.

Ultra-Microscopic Blood.

Reicher showed specimens of blood taken from a narcotised dog to demonstrate his opinion given in a former paper. The dog was kept without food for a day and a half before the experiment, and specimens of the blood taken for confirmation. In the blood for demonstration fine particles with a distinct molecular movement were visible, which were rarely to be found before the animal was narcotised. In place of one or two in the field, as often occurs, an innumerable quantity could be seen moving about under the influence of the Brownian molecular movement.

Convulsions and Cramps.

Benedikt next gave a long rehearsal of convulsive and choreic movements, and affirmed that epilepsy was primarily a psychical disease. The epileptic attack commences with an irritability and terminates with a discharge, which acts as a shock, followed by choreic movements. In apoplexy of the brain these epileptic contractions also occur, which leads one to conclude that the attacks are due to a vasomotor shock. Beyond this hypothesis he thought it unwise to venture. During the period of repose the patient should have very little medicine given, but when symptoms of a storm are presaged the drug should be pushed energetically. In many cases the disease is located in the external coverings of the brain, and exists from childhood. Operative results are very disappointing, and not to be commended, as the attacks often continue after extirpation of the centre. In one of his cases hemiparesis followed the operation, but in others he has had recovery, which hardly compensates the labour and risk.

Frankl agreed with Benedikt in the treatment, but thought if the motor centre were proved to be in the brain it should be removed, although hemiparesis should supervene, as contractions and crampings are to be expected. The best case he had to record was one operated on 10 years after the first attack. After the operation the fits disappeared entirely, with no bad effects.

Eiselsberg thought that cases of epilepsy of the Jacksonian type were the only ones suitable for operation. Teleky suggested removing all tumours; though paresis did occur, it was better than the fits. Redlich brought up the poison theory, and could not see where operation would do any good in genuine epilepsy.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Small-pox in Leith.—During the past week 10 cases of small-pox have been notified in Leith, and 4 cases in Edinburgh. All the cases have been traced to a single source—a patient attacked about three weeks ago. He was a sailor who arrived in port on December 24th, and sickened three days later. For a time there was difficulty in tracing all contacts, but lately the Medical Officer of Health discovered that two lady canvassers visited the house two days before the patient was removed to hospital. These canvassers had afterwards made a number of business calls at different houses, and have evidently served as the carriers of infection, for all the persons attacked have either been visited by the canvassers or by some person with whom the canvassers had come in contact. The Edinburgh cases are traceable to the same source. Several cases of cerebro-spinal fever have also occurred in Edinburgh this week. It may be remembered that it was towards the end of January last year that the malady became prevalent.

Infectious Disease in Glasgow.—The Medical Officer of Health reports that during the past fortnight there have occurred 1,288 cases of measles, the number of cases of the disease in the hospital being greater than ever before. The localised epidemic of enteric fever traceable to infected milk from a Lanarkshire dairy has accounted for nearly 60 cases, of which several have proved fatal. From September to December inclusive, 13 cases of meningitis were bacteriologically investigated, with positive results in 5; during the same period 23 contacts were examined for the presence of the meningococcus in the nasopharynx, with 3 positive results. There were 6 cases of suspected plague, of which 2 were genuine, one a young woman who died on August 31st, and the other a boy, admitted to Belvidere Hospital in October. Of 94 rats examined, taken from the city and from shipboard, only one was found to be infected. The citizens of Glasgow have been greatly agitated over the dismissal of three medical assistants of Ruchill Fever Hospital, one of the Corporation hospitals for the treatment of infectious diseases. It appears that there has been considerable friction for some time past among the staff. The nurses say they have been overworked, and that the hospital is understaffed. The dismissed assistants are alleged to have disregarded some of the regulations relating to this office, drawn up some years ago. They, however, complain that: (1) there are "an insufficient number of nurses in certain wards"; (2) "an insufficient number of sisters or charge nurses"; (3) "inexperienced nurses in charge of wards"; (4) "inefficient ambulance administration." The Local Government Board have instituted a preliminary investigation into the conduct of the hospital by Professor Henry Littlejohn, of Edinburgh University.

Lord Rectorship of Glasgow University.—The Liberal candidate is the Prime Minister, the Right Hon. Sir Henry Campbell-Bannerman, while the Unionists have adopted Lord Curzon as their representative.

Lord Rectorship of Edinburgh University.—The names of the candidates cannot be definitely announced as yet. The Unionists are understood to be negotiating with Lord Milner, while the Liberals have met with a disappointment in the refusal of Mr. R. B. Haldane to allow himself to be nominated for a second term. It is understood that Mr. John Morley will now be approached, and, failing him, a selection may be made from among the names of Lord Loreburn, Sir Edward Grey, Mr. Asquith, and Mr. L. Harcourt. Sir Frederick Treves's name has also come up, but in selecting him there could be no political contest, which is regarded as undesirable.

Seaforth Sanatorium.—This sanatorium, gifted to the counties of Ross and Cromarty by Colonel and Mrs. Stewart Mackenzie, of Seaforth, who have not only built and equipped it, but endowed it for all time with a gift of £100,000, was formally opened on January 16th. The institution is for the treatment of early phthisis, and the tests for admission are inability to be treated in commercially conducted sanatoria, and residence in the county of Ross or Cromarty. Twenty-four cases can be treated, and there is a possibility of providing for 30 or 40 patients ultimately. The opening ceremony was performed by Mrs. Stewart Mackenzie, and Colonel Stewart Mackenzie, in a short speech, intimated he had appointed Dr. Maclean, Fortrose, as medical superintendent. He read a telegram from the King wishing the sanatorium all success, and another of congratulatory nature from the Local Government Board. The architect of the sanatorium was Mr. MacBeth, Inverness.

Students' Disturbance at Glasgow.—At the Glasgow University Court, a letter was read from the Students' Representative Council offering to repair the damage done at the recent graduation ceremony by a payment of £10 or £12. A long discussion followed, the outcome being that Dr. McVail's motion declining to reopen the matter was carried against a single vote that the offer be accepted. The feeling was, that it was unwise to create the impression that the students might do what damage they liked provided they paid for it.

BELFAST.

Medical Meeting at Downpatrick.—A meeting of medical men was held at Downpatrick last week to consider whether, and to what extent, they would identify themselves with the anti-tuberculosis movement. The chair was occupied by Dr. Wybrants Olpherts, and practically all the local members of the profession were present, or sent apologies. A resolution was passed agreeing to wait on the District Council and ask their co-operation in the matter, and also to ask the members of the veterinary profession to give their help. The meeting seems to have been a most harmonious one, and sets an excellent example to other districts, for there can be no doubt that the advent of tuberculosis exhibitions, meetings, etc., in many places has stirred up a good deal of jealousy and bad feeling, accusations of advertising and other unethical proceedings being freely made.

Medical Men and Municipal Politics.—The municipal elections last week resulted in the return of two more medical men, in addition to the already considerable number in the Corporation. Dr. Andrew Trimble was returned for Dock Ward as the nominee of the Citizens' and Conservative Associations, and Dr. Robert Thompson for Cromac Ward as an Independent. The recent Local Government Board inquiry into the health of the city has called attention to health matters in a way that has never been known before, and the health reformers have practically swept the board at these elections. A few more such elections would cleanse municipal politics of its worst elements, and would immensely improve the social conditions of the working classes of the city.

Public Health.—During the past week the death-rate has continued abnormally high, being 28 from all causes, and 3.8 from zymotic diseases. Measles and whooping-cough are specially prevalent.

LETTERS TO THE EDITOR.

THE *STAR* AND THE MEDICAL PROFESSION.

To the Editor of The Medical Press and Circular.

Sir,—I must thank the Editor of the *Star* for his courteous reply to my letter. It is evidently not necessary to continue a controversy in your pages. Everyone of your readers can now judge for himself, from what the Editor has written, how far he is qualified to speak with any authority on the question upon which he dogmatises. They will, I believe, all agree with me that the Editor displays that little knowledge of the subject which is so extremely dangerous a thing. The Editor's unfortunate bias against the profession is exemplified by his innuendo in relation to the vaccination of infants "before the reduced fees came into operation." It is perfectly absurd to suggest that the whole medical profession, having had the results of vaccination before them from the days of Jenner till now, should have failed to recognise any evil effects that the process could bring about. The Editor ignores the mass of bacteriological knowledge accumulated within recent years, which gives a solid foundation of science to the necessarily empirical observations of Jenner; and prefers to rely upon the opinions of the very rare anti-vaccinist practitioners, most of whom have no claim by pathological research or by clinical experience to any position of authority whatever. Professor Crookshank's work was discredited years ago. The quotation used by the Editor of the *Star* speaks of the "*futility* of the practice," not of its harmfulness. The *utility* of the operation has been demonstrated on the biggest scale a million times, and sufficiently in small-pox hospitals, where vaccinated attendants never take the disease, whilst the unprotected mostly do. In the old days of arm-to-arm vaccination the number of cases followed by any untoward result was so small as to be almost negligible; since the introduction of the calf lymph system the danger has been entirely done away with. Small-pox is extinguished wherever vaccination is effectively carried out; and even had the operation been attended by the remote dangers imputed to it by its reasonable opponents, the risk would have been well worth incurring, in view of the incalculable benefits Jenner's discovery has conferred upon mankind.

I am, Sir, yours truly,
January 16th, 1908. A Surrey Doctor.

To the Editor of The Medical Press and Circular.

Sir,—The astounding reply in your last issue from the Editor of the *Star* to a Surrey doctor's letter almost recalls the nursery rhyme, "Twinkle, twinkle, little star, how I wonder what you are." However, as the Editor appears to treat the matter seriously, and thinks the reason why the majority of medical men have heir own children vaccinated can be accounted for as due to "ignorance" on their part, may I ask what evidence he can produce to support his idea that ignorance on the subject prevails amongst the vast majority? In a case reported in the *Daily Telegraph* (January 10th, 1905) in which a "conscientious objector claimed exemption on the ground that the profession were not unanimous," and as it might enlighten your correspondent as to a judicial opinion on the weight of evidence on the question I venture to reproduce it.

The Magistrate's Argument.

An applicant for a vaccination exemption certificate at Westminster repeated the usual formula, "I conscientiously believe that vaccination will be prejudicial to the health of my child."

Mr. Curtis Bennett: On what do you base that statement?

Applicant: On the fact that the medical opinion of the country is divided as to the efficacy of the operation.

Mr. Curtis Bennett: I do not think so. Doctors are nearly all agreed. If ninety-nine out of one hundred say that a thing is right they are more likely to be correct than the one who differs. Have you any other ground?

Applicant: You refuse a certificate?

Mr. Curtis Bennett: I do.

I am, Sir, yours truly,
Brighton, January 18th, 1908. C. H. S.

INHERITED SYPHILIS.

To the Editor of The Medical Press and Circular.

Sir.—Dr. Walsh must kindly be satisfied with the assurance that my name would add no weight to my facts; and as it could not strengthen my arguments, I prefer to remain unknown. The opinions which I put forth years ago in your pages, and have reiterated at intervals since, have been strengthened by accumulating experience—the experience of an average practitioner, not closely engaged in the treatment of syphilis; merely one who has kept eyes and ears open to receive the knowledge of that disease which is thrust upon everyone engaged in any department of practice. Laymen do not read medical papers, and I do not think—as Dr. Walsh seems to fear—that any practitioner would abate his zeal in the treatment of a syphilitic patient because of a doubt about the danger of conveyance of infection to wife and progeny. With regard to treatment, I believe the only cases that come to grief are those who do not undergo systematic and sufficiently prolonged mercurial treatment, those with bad constitutions, and those who lead intemperate and dissolute lives. I believe that syphilis is virtually a curable disease in patients of sound constitutions who will submit in every way and throughout to the guidance and treatment of their medical adviser. I have never seen syphilitic children begotten of fathers of this type after lapse of sufficient time. There cannot be the least doubt that large numbers of children among the poor are labelled syphilitic who have no valid claim to such a vile distinction. Rickets, tuberculosis, and malnutrition, alone or combined, often produce a type closely resembling the syphilitic. The teeth are often honeycombed or spinous, and are mistaken for the typical syphilitic teeth of Hutchinson. The teeth of Hutchinson are not present even in 5 per cent. of children with other unequivocal signs of the inherited taint. So with eye diseases and diseases of the bones. Syphilitic keratitis is rare, and simple necrosis and tubercular disease are often mistaken for syphilitic affections of the bones.

I am, Sir, yours truly,
An Average Practitioner.
January 16th, 1908.

THE BROWN DOG INCIDENT

To the Editor of The Medical Press and Circular.

Sir,—Will you very kindly allow me to reply to "A Surrey Doctor," who has vehemently and bitterly attacked my letter on "Medical Students and Vivisection"? It is easy, but not courteous, to shower abuse and make accusations of "false statements"; but, while heartily welcoming the evident horror and indignation with which "A Surrey Doctor" repudiates the possibility of scientists and doctors being guilty of cruelty to animals, I refer him to the *Journal of Physiology* and other professional journals, in which he will find recorded by the vivisectors themselves the most "terrible and revolting" tortures inflicted by them upon dogs and other animals.

With regard to the humanity of physiologists, I may point out that the absolute callousness and refined cruelty of many noted vivisectors is so well known as to be beyond dispute; that an eminent vivisector stated before the Royal Commission on Vivisection in 1876 that he only used anæsthetics for his own convenience, and that he had "no regard at all" for the sufferings of his victims; also that it has been said by a prominent licensed vivisector before the present Royal Commission on Vivisection that experimenters who should operate *without anæsthetics* would be worthy of all praise and admiration! (Question 4,160, Blue Book, Minutes of Evidence).

It is, of course, impossible for a man with humane feelings to become a vivisector. That vivisection is to the last degree demoralising in its effects no reasonable, unprejudiced person can doubt. Dr. S. Haughton stated to the Commission of 1876 that to accustom medical students to witnessing vivisection would be to let loose upon the world "a set of young devils." How far that prognostication has been verified by the recent riotous, insulting and ungentlemanly behaviour of certain medical students I leave the public to judge. Unquestionably no other class of young men would be capable of such conduct.

Those medical men who desire to help to cleanse their profession from the stain of inhumanity should follow the excellent, noble, and *manly* example of the

1,250 doctors who have signed a petition praying that dogs may not be vivisected; join the ranks of the many doctors who are making a determined stand against vivisection in any shape or form, and enrol themselves in the newly-formed International Medical Anti-Vivisection Association.

Public opinion will not much longer sanction experimentation upon living animals—torture. The Paris Faculty of Medicine has grandly led the way by rejecting the offer of a chair for vivisection. England, ever in the forefront of humane movements, *cannot*, without crushing shame, tolerate what another nation denounces as immoral and inhuman. England must now go on even beyond the lead given by France, and must at once sweep the vile and horrible practice out of her Universities and abolish it altogether, or be for ever disgraced before the whole world.

I am, Sir, yours truly,
C. A. M. Bailey,
Hon. Secretary National Canine Defence League.
London, S.W., January 17th.

OBITUARY.

C. J. WRIGHT, M.R.C.S., L.S.A.

A well-known Leeds surgeon has passed away through the death of Professor Charles James Wright. He had been seriously ill for only a few days, though visibly failing in health for some time past.

Obstetrics and gynæcology were the two branches of the healing art to which Mr. Wright particularly applied himself. From 1884 up to the summer of last year he had been Professor of Obstetrics at the Yorkshire College, and so continued when the College emerged into a University, and he sat on the Court of Governors. In the first batch of honorary degrees conferred by the new University upon local medical men of distinction, Mr. Wright was accorded that of a Master of Science. He was a member of the Royal College of Surgeons, England (1864), and licentiate of the Society of Apothecaries (Leeds and Guy's Hospital) (1865), and also a Fellow of the Obstetrical Society, London. When, about six months ago, Mr. Wright placed his resignation in the hands of the Council of the University, after 41 years of continuous service on the teaching staff of the School of Medicine, it was accepted with deep regret, and the Board of the Faculty of Medicine likewise placed on record their sense of obligation to him for his long and sincere work.

Mr. Wright was a native of Wakefield. He was sent to the Leeds School of Medicine, and to Guy's Hospital. It was Mr. Wright's destiny to become closely associated with this establishment, first as Demonstrator of Anatomy, from 1865 to 1870, next as Lecturer on Physiology from 1870 to 1884, and finally as Lecturer on Midwifery.

He had a large influence on the destinies of the Leeds Hospital for Women and Children, to which he was senior honorary surgeon for many years. On the whole, this may well be considered as his most valuable work, for although he had of late years been obliged to limit his service to that of a consulting surgeon, he did much to promote the growth and efficiency of the institution. He had been with it during all its changes and developments, and it must have been very gratifying to him to see it move from a poorly equipped into a thoroughly up-to-date establishment. Genial and kind-hearted, Mr. Wright was much liked by the other officials and the patients, and, even when not in very robust health himself, he sacrificed much of his time in ministering to the needs of others.

DR. PATRICK CANNING.

We regret to record the death of Dr. Patrick Canning, which took place in Dublin during the past week. Dr. Canning, who was only 35, had been ailing only a couple of days. He visited Dublin to undergo a slight operation, but was attacked with pneumonia, and died after a brief illness. At the Royal University, Dr. Canning had a distinguished career, and the ability which marked his subsequent career was shown at an early stage at the Mater Hospital and the Catholic University Medical School. Some years ago he was appointed Physician to Maynooth College.

Medical News in Brief.

Royal College of Surgeons of England.

A quarterly meeting of the Council of the College was held on Thursday last, Mr. Henry Morris, President, in the chair.

Members and Hospital Appointments.—A report from the committee on the annual report of the Council was read with reference to the resolutions carried at the recent meeting of fellows and members. With regard to the resolution asking the Council to use their moral influence with hospital authorities to recognise members of the college as having equal rights with Provincial, Scotch, and Irish Graduates to become candidates for hospital appointments, the Council decided to refer back the recommendations of the committee for further consideration.

Members on the Council.—Regarding the question of the representation of members on the Council, it was decided to inform the mover and seconder that the resolution had been laid before the Council, and that the views of the Council upon the question referred to would be found in the last annual report of the Council. The suggestion that a poll of fellows and members should be taken upon the proposal for the direct representation of members upon the Council was also considered, and the Council saw no reason to adopt the suggestion.

Question of Hoods.—The Council also decided not to comply with the request contained in the resolution regarding the addition of a hood to the gown already worn by fellows and members. The committee reported on this subject as follows:—"The committee believe that the hood is generally understood to be distinctive of a degree. In this sense it forms part of the academic costume of a University, but would not be appropriate for a college. For this reason, and as hoods do not appear to be in general use among colleges of similar standing to the Royal College of Surgeons of England, the committee recommend the Council not to comply with the request."

With reference to the resolution asking the Council to report as to their willingness to join the Royal College of Surgeons and its work with the University of London, the Council determined to inform the mover and seconder that the matter had been much discussed in the past, and still occupies their attention.

The President reported that he had given evidence on behalf of the College before the Home Office Committee on the London Street Ambulance, and a vote of thanks was given to the President for the able and efficient manner in which he had represented the College in the matter, and for the valuable information obtained and submitted by him regarding the ambulance systems in Paris, Berlin and Boston.

The revised standing rules relating to the office of conservator of the museum were approved, and it was determined to proceed to the election of a conservator in the vacancy occasioned by the death of Professor Stewart, at the next meeting of the Council on February 13th.

Mr. Henry Morris was appointed Hunterian Orator for the year 1909, and Mr. Thomas Bryant, ex-President, was re-elected the representative of the College upon the Council of Queen Victoria's Jubilee Institute for Nurses.

A committee was appointed to prepare a circular to the fellows and members upon the question as to whether women should be admitted to examination for the diplomas of the college. A suggestion that arrangements should be made for serving tea to readers in the library was adopted.

Mr. J. L. Graham-Jones, B.A., Cambridge and St. Thomas's Hospital, and Mr. C. H. Smith, Liverpool, having passed the required examinations and conformed to the by-laws, were admitted members of the College. Diplomas of the license in dental surgery were granted to Mr. S. S. Parkinson and Mr. Wilton Thew, of Charing Cross and Royal Dental Hospitals.

Society for Relief of Widows and Orphans of Medical Men.

A QUARTERLY Court of Directors of the above Society was held on Wednesday, January 8th, at 5.30 p.m., at 11, Chandos Street, Cavendish Square, Dr. Blandford (President) in the chair. Twelve members of the Court were present. Applications for membership were received from five medical men, and they were duly elected members of the Society. Since the last Court, one of the annuitants of the Society, æt. 91, had died. She had been in receipt of grants since 1866, and had received £2,824 from the Society. Her husband had paid in subscriptions £27 6s. Three letters had been received from the widows of medical men, asking for relief, but this had to be refused, as their husbands had not been members of the Society. £534 was distributed as a special Christmas present amongst the annuitants of the charity in December, each widow receiving £10, each orphan £3, and those in receipt of grants under the Copeland Fund, £5 each. The sum of £1,257 10s. was voted for the payment of the half-yearly grants to the 48 widows and 16 orphans at present on the books of the Society. Relief is only given to the widows or orphans of deceased members. Membership is open to any registered medical practitioner who at the time of his election is residing within a 20-mile radius of Charing Cross. Full particulars of the work of this valuable Society, and application forms, may be obtained from the Secretary at the offices of the Society, 11, Chandos Street, Cavendish Square, W.

Sleeping Sickness in Rhodesia.

A REPORT just received in Liverpool from the expedition of the Liverpool School of Tropical Medicine despatched to Rhodesia for the purpose of endeavouring to check the spread of sleeping sickness in Central Africa, of studying the disease, and of investigating the distribution of biting flies, says that the fly Glossina palpalis is found along both banks of the Luapula from a point near Kapwepwi's village. Glossina palpalis (possibly another species) is found scattered over practically the whole of the Luapula division. "Only one case of human trypanosomiasis has been found as yet. The neck glands are very decidedly enlarged, and trypanosomes are present in fairly large numbers in the gland juice. It presents no symptoms of the disease whatever. It is interesting to note that this case is the only one in the village, a fairly large one, although Glossina morsitans is found plentifully in the village and surrounding country. A fair percentage of the natives have distinctly palpable neck glands, but on puncture these are found not to harbour trypanosomes. This means that the recognition of the disease by palpation is one which a medical man alone can apply satisfactorily. The Administration considers the advisability of appointing special travelling medical officers, whose duty it will be to travel constantly through the threatened districts at least—*i.e.*, along the Luapula and along the northern border, looking for cases.

Action Against "Tooth Extractors.

THE extraction of a molar tooth was the basis of an action concluded at the Birmingham County Court on January 10th. The plaintiff, Annie Barlow, domestic servant, claimed damages against Messrs. Cargill and Smith, who described themselves as tooth extractors and adaptors, for personal injuries sustained through the alleged unskilful pulling of a tooth. The operation complained of was performed by Mr Cargill, who was not a registered dentist, but who claimed to have had a long experience both in the service of qualified dentists and in practice on his own account.

Dr. Emery, who saw her four days after the extraction, found bad septic poisoning, which he attributed to the use of unclean forceps. He also stated that the jaw was badly lacerated, and that he had to remove three detached pieces of dead bone.

Experts who examined the patient some time later said the appearances were consistent with a perfectly skilful extraction. The septic poisoning might have been due to other causes than unclean forceps, they declared, and one witness described the mouth as the home of germs. Defendant stated that he carefully sterilised his forceps after operating on a patient.

The jury found for the defendant, and judgment was entered accordingly.

Great Northern Central Hospital—Clinical Lectures.

IT is announced that the attendance at the course of lectures given at the Great Northern Central Hospital, London, has fully justified the action of the medical staff in their attempt to utilise the clinical material at their disposal for teaching purposes. It is therefore proposed to continue the series of lectures and demonstrations during the remainder of the winter months, and it is hoped that it will be possible to arrange them more on the lines of actual clinical lectures than of set addresses. The time of the lectures has been altered from 3 o'clock to 3.30, in order to meet the wishes of those who attend these demonstrations.

The Coombe Hospital and the Central Midwives Board.

WE are glad to learn that the Central Midwives Board has adopted the unanimous report of their Standing Committee recommending that the newly-appointed Master of the Coombe Hospital should be recognised as a teacher of midwives under the rules of the Board. Dr. Gibson's name has accordingly been added to the list of recognised teachers, and pupil midwives can be again trained at the Coombe Hospital in accordance with the rules of the Central Midwives Board. This decision is manifestly in accordance with the dictates of strict justice, as it would have been most unfair to have punished Dr. Gibson for errors committed before he had anything to say to the management of the hospital.

Royal College of Physicians and Surgeons.

AT the First Professional Examination, held on January 7th, 8th, 9th, and 10th, 1908, the following gentlemen were approved in the subjects indicated, viz.:—

Chemistry and Physics.—Gilbert Bailey, Basil F. Beatson, William H. Broughton, Frederick W. Campbell, Rowland B. Campion, Nai Cheune, Henry D. S. Close, Edward P. Drabble, Charles A. R. Gatley, John L. D. Lewis, Victor A. Luna, Leonard R. Pickett, Henry C. Rigg, William A. Thompson, Claude de B. Thomson, Claude W. Treherne, Arnold Viney, and Sydney Wilkinson.

Chemistry.—Ahmed Abdel-Al, Frank C. Cowtan, Alexander R. Esler, Maberly S. Esler, Hassell D. Field, Meredydd Foulkes, Francis H. Guppy, Frank M. Hughes, Gerald N. Martin, David Scott, Ivan L. Waddell, and William N. P. Williams.

Physics.—Allan S. Coalbank, William T. Flooks, Owen Gwatkin, William F. Mason, Eugene A. J. Murphy, Edmund U. Russell, Charles P. C. Sargent, and Henry S. Young.

Biology.—Ramrao Belcrushma Agaskar, George Aspinall-Stivala, Gilbert Bailey, William S. Birch, Herbert Chorley, Arthur G. B. Fenwick, Geoffrey Garland, Charles A. R. Gatley, William E. Hallinan, Leslie P. Harris, John R. Hayman, George B. H. Jones, Edmund T. H. Lea, David Lewis, Victor A. Luna, Alexander Macrae, Reginald V. Martin, Arthur G. Morris, Eugene A. J. Murphy, Frank A. M. Nelson, Jorabhai Bhaibabhai Patel, Montague Pern, George B. Pritchard, Walter A. Reynolds, Henry C. Rigg, Charles P. C. Sargent, Jelal Moochool Shah, Cuthbert Shaw-Crisp, William A. Thompson, Chunilal Bhimbhai Vakil, William C. Whitworth, William N. P. Williams, and William Wörger.

At the Preliminary Science Examination for the Licence in Dental Surgery held this month, the following gentlemen were approved in the subjects indicated, viz.:—

Chemistry and Physics.—Robert R. Adams, Edwin R. Bailey, Henry L. Bailey, Stanley M. Gardner, Robert J. Herley-Mason, Guy W. E. Holloway, Sidney W. Ingram, William H. Keay, Sidney Saxton, Herbert Thornton, and Thomas R. Trounce.

Chemistry.—Ernest W. Bacon, Arthur R. Goddard, Cyril A. Pollard, James S. Robinson, George W. Royle, and James Sharp.

Physics.—Charles R. Faulkner, Thomas L. Fiddick, Roy W. List, William M. Potter, and Frank P. Sturdee.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT PATHOLOGICAL LITERATURE.

Pathology of the Cerebro-Spinal Fluid.—Forbes reports the results obtained from bacteriological and cytological examination of the cerebro-spinal fluid from 140 cases of sick children (*Quarterly Journal of Medicine*, vol. i., No. 2, page 1). The series included 57 cases of tuberculous meningitis, 6 of meningo-coccal meningitis, 16 cases in which other organisms, the pneumococcus, streptococcus, staphylococcus, and bacillus coli communis, were found, 3 cases of syphilitic meningitis, 14 cases in which other cerebral conditions, such as abscess, were present, and 14 cases with meningeal symptoms due to such diseases as pertussis and broncho-pneumonia. In the tuberculous cases the bacilli were found in the cerebro-spinal fluid in 27 cases by staining the lymph clot, which formed on standing. Cytological examination showed an excess of lymphocytes in 31 cases, in some of which a differential count showed as much as 97.5 per cent. In severe meningo-coccal cases the cerebro-spinal fluid was found to be turbid with an excess of polynuclear neutrophiles, and to contain a considerable quantity of albumin. Meningococci were obtained from the fluid in all severe cases. In less acute cases the fluid is clear with a faint trace of albumin, and a scanty cell deposit chiefly of neutrophile cells, while in chronic cases no albumin is present, and the only cells found are a few degenerated lymphocytes. The pneumococcus was found in 9 cases, in most of which an excess of neutrophiles was present. In four cases out of five of streptococcal meningitis streptococci were obtained from the fluid during life, and in one case a pure culture of the colon bacillus was found, abundant polynuclear cells being also present in this case. In syphilitic cases the lymphocytes predominated, reaching as high as 92 per cent. of all cells present in one case, while the fluid proved sterile in all cases examined. In eight cases of cerebral symptoms occurring in different diseases the fluid after centrefugalising and evaporation yielded numerous minute colourless rhomboid crystals, but the nature of these and their pathological significance has not been determined. M.

A Ten Years' Study of the Cupar Water Supply.—Dr. Douglas gives an account of his study of the Cupar water supply, and the results are of interest, not only locally, but also from their bearing upon water supplies and water analysis generally (*Edin. Med. Journal*, January, 1908, p. 42). The supply is an upland surface water obtained from numerous feeders from the neighbouring higher levels, the land being cultivated, some of it arable, the rest pasture land. The soil is of limestone formation, and the natural springs in the neighbourhood are of very hard water. It is not so, however, with the water under examination, as repeated analyses over a period of 13 years have shown only about 12 degrees of total hardness. The water is filtered through sand, and then passes through a 7-inch pipe to a small reservoir near Cupar. The pipe, after a series of years, became so narrowed by incrustation as to suggest the necessity of laying down a new pipe. Before doing so, however, the Glenfield patent scraping process was applied, and proved a complete success. Bacteriological examinations were made almost every month, and special attention was paid to the effect of filtration upon the germ content. These observations confirmed the opinion already held that a filter does not act as such until the slime layer of organic deposit has been formed. When this layer is complete, usually over 90 per cent. of organisms were found to be removed by the filtering process. The germ content of the water at the point of delivery was, however, found to be much greater than at the place where it issued from the filter bed, probably owing to the increase in number of organisms in geometrical progression when allowed to stand for a few hours in the pipes. The range of alkalinity of the water was also tested, and appeared to be rather greater in the winter than in the summer, but the difference did not appear to have any effect upon the germ content. The mean germ content of the water as first collected was found to be from 900—1,000 organisms per c.c. M.

Persistent Ductus Arteriosus Associated with Sudden Death.—A woman, æt. 28, who had never previously been ill, and who had passed through a first pregnancy without any symptoms of dyspnœa or cyanosis, died suddenly, just after a second successful delivery (*Bulletin de la Soc. Anat. de Paris*, Feb., 1907). She got an acute attack of dyspnœa, with a sensation of choking and severe cardiac palpitation. Her face became blanched and drawn, the pulse rose to 104, her respirations to 40, and a trace of albumin appeared in the urine, but there was no cyanosis. The apex beat was found in the sixth intercostal space just inside the nipple line; there was no increase of cardiac dulness; no murmur was heard, and though the sounds resembled those of the fœtal heart, there was no arrhythmia. The blood pressure was 160 m.m. Hg. The patient was bled, and 300 c.c. of blood were withdrawn, but without relief to symptoms, and death ensued after an illness of 12 days. At the autopsy the only abnormality found was a persistent ductus arteriosus, 10 m.m. in width, and surrounded at its base with a strong fibrous ring. The aortic and pulmonary walls were of about the same thickness throughout. M.

Changes in Body Temperature Produced in Dogs by Morphia and Ether.—Mills (*Johns Hopkins Hosp. Bulletin*, Dec., 1907, p. 470) reports observations on the following points:—(1) The temperature curves of dogs taken during operations after injection of morphia and anæsthetisation with ether; (2) the effect on temperature of morphia alone; (3) the effect on temperature of ether alone; (4) the variations of morphia and ether temperature curves caused by the application of external heat. The conclusions arrived at were as follows:—(1) The normal temperature of the dog is between 102° F. and 103° F.; (2) injection of ¼ gr. of morphia causes a fall of temperature of from 3° to 5°, the lowest point being reached in about two hours, and the temperature gradually returning to normal as the effects of the drug pass off; (3) ether alone causes a fall of temperature, but the effect rapidly passes off when the drug is discontinued; (4) morphia and ether in combination cause a fall of 6° on the average; (5) if heat be applied externally to dogs under morphia or ether, the fall in temperature is much less, and the temperature may soon return to normal; (6) the amount of fall of temperature does not seem to affect the prognosis; (7) the nature of the operation has no definite bearing on the temperature curve. M.

Opsonic and Agglutinative Reactions in Cerebro-Spinal Fever.—Houston and Rankin publish (*British Medical Journal*, Nov. 16th, 1907) an account of researches made into the opsonic and agglutinative powers of the blood-serum in cerebro-spinal fever as observed during the recent epidemic in Belfast. The following points are brought out:—(1) Opsonic estimation is of value in the diagnosis of suspected cases of cerebro-spinal meningitis. Of the cases examined within the first four days of the disease, only a low percentage gave positive results; on the fifth day, 3 out of 5 gave positive results; from the 6th to the 133rd day, 125 out of 130, or 96.1 per cent., gave positive

results. (2) The opsonic power of normal blood for the meningococcus is extremely low. A mere glance at the preparation was usually sufficient to distinguish the serum of a genuine case of the disease from normal serum. (3) The meningococcus may lose its power of reaction by prolonged growth on artificial media. This result is compared with the observation of Flexner that the meningococcus, under such conditions, may lose its pathogenic properties. (4) The cerebro-spinal fluid has always lower opsonic and agglutinative properties than the blood. (5) In convalescent cases the reaction disappears quickly. (6) The serum of cerebro-spinal fever, when exposed to heat, or kept for some time, loses its opsonic power, but retains its agglutinative power. (7) The opsonic method should prove of value in estimating the potency of proposed therapeutic sera. (8) True cases of epidemic cerebro-spinal fever are always due to a meningococcus having the same agglutinative and opsonic reactions. On the other hand, there is probably a distinct organism for posterior basic meningitis, differing from the meningococcus in its opsonic and agglutinative reactions. The authors obtained and examined cocci obtained from London, Edinburgh, Glasgow, New York, and Hamburg, before coming to these last conclusions. The paper is one of interest and importance, and well repays perusal.
R.

Blood Cultures.—Rhea and Emmons report (*Boston Med. and Surg. Journal*, Dec. 19, 1907) the results of 91 consecutive blood cultures made in the Boston City Hospital as part of the routine of the Pathological Department. Of the 91 cultures, 36 were positive, 55 negative. The following organisms were recovered: streptococcus pyogenes in 13 cases; pneumococcus in 6; staphylococcus pyogenes aureus in 7; gonococcus in 2; staphylococcus pyogenes albus in 2; bacillus mallei in 1; bacillus mucosus capsulatus in 1; bacillus anthracis in 1; bacillus paratyphosus in 1; bacillus aërogenes capsulatus in 1; staphylococcus citreus in 1; bacillus typhosus in 1. Of the 13 patients with streptococcal infection, 8 died; of the 7 patients infected with staphylococcus aureus, 6 died; the 2 patients with gonococcal infection recovered. All the cases of pneumococcal infection were consequent on lobar pneumonia; 5 out of 6 died, 1 recovered. The authors add to the value of their paper by giving notes of the autopsies of many of the fatal cases. R.

Verrucæ Plantaris.—Bowen publishes (*Boston Med. and Surg. Journal*, Dec. 12th, 1907) a careful description of the histology of verrucæ plantaris, which he states to be very common among boys and young men in his practice. He regards the condition as probably infective, slight lesions from irritation offering a path of entrance to the infecting organism. The tumour is most commonly multiple, and may occur either on the palm or on the sole of the foot. Histologically, the growth shows at its periphery the ordinary structure of a wart—papillary enlargement, with downgrowths of the rete, and a marked hyper-keratosis. The granular layer is much increased in thickness. In the centre of the tumour, however, is the characteristic lesion. This is a vacuolation of some of the rete cells, which causes them to assume a rounded form and a larger size than the neighbouring cells. Concurrent with the vacuolation is keratosis round the periphery of the cell. As the vacuolation becomes more marked, the cells fuse together, and an irregular network results, strewn with masses of kerato-hyaline. In many of the cell nuclei bodies were found, whose appearance aroused the suspicion that they might be some form of protozoa. They were small, round bodies, highly refracting, and in some instances apparently concave or crescentic. They were stained by acid reagents, and were easily distinguishable from the nuclei in which they lay. It was, of course, possible that they were the results of some form of cell degeneration. R.

Lice and Relapsing Fever.—Mackie, who has recently investigated an outbreak of relapsing fever in the Basik Mission Settlement, brings forward (*British Medical Journal*, December 14th, 1907) reasons to believe that the body-louse is an important agent in the transmission of the disease. Practically all the boys in the settlement suffered from the disease, while very few of the girls were affected. On examining the conditions under which the two sexes lived, Mackie was astonished to find that whereas the boys' bodies were infested with lice, the girls were almost free. On the other hand the girls' quarters were infested with bugs, from which the boys' quarters were almost free. On dissection of lice taken from the infected wards Mackie found that their bodies contained plentiful living and multiplying spirilla. The stomach of the louse was the chief seat of multiplication, and this was carried on in the face of active digestion, and after the disappearance of all other cellular elements. Other organs became secondarily infected. The secretions expressed from the mouths of infected lice contained numbers of living spirilla. The ovary was frequently infected, but spirilla were not found in deposited ova. As the epidemic subsided the number of infected lice diminished. Attempts were made to infect a monkey by means of lice, but they failed. Dissection of bugs revealed the presence of spirilla in the alimentary tract in small numbers, and only in the presence of fresh blood. They were scarcely more numerous than in the human blood, when allowance was made for the concentration of the blood by absorption of the fluid parts. There was never any sign of multiplication, and no organ, other than the recently filled stomach, was found to contain spirilla.
R.

Nature of the Parathyroids.—Forsyth (*British Medical Journal*, November 23rd, 1907) discusses the nature of the parathyroid glands and their probable relation to the thyroids. (1) He combats the view that the parathyroids are to be regarded as essential to life, as the only evidence in favour of it is inconclusive. It has not been shown, as claimed, that removal of the parathyroids is fatal, while that of the thyroids alone is comparatively harmless; the difficulty of discovering and separating the parathyroids prevents any conclusive proof of this sort. (2) He rejects Sandström's theory that parathyroid tissue is embryonic thyroid tissue. It is a pure assumption. Welsh, Verdner and others distinguished these tissues histologically with ease. Neither has it been shown that parathyroid tissue can develop into thyroid. (3) He puts forward the hypothesis that the parathyroids and thyroids are functionally identical, and that the histological differences are due to differences in the vigour of secretion, and in the lymphatic drainage of the two tissues. In support of this doctrine he points out that the recognisable differences depend on the varying proportions in which epithelial cells and secreted material are present. In both mammals and birds he has met thyroids which possessed parathyroid properties, and intermediate types are comparatively common. These statements are borne out by micro-photographs. R.

The Physiological Relation of the Uterus and Ovaries.—Carmichael and Marshall (*British Medical Journal*, November 30th, 1907) publish the results of experiments performed in order to observe the effects on the uterus of removal of the ovaries, and on the ovaries of removal of the uterus. They came to the following conclusions:—(1) The removal of the ovaries in young animals (rodents) prevents the development of the uterus and Fallopian tubes, which remain in an infantile condition. The subsequent growth of the animal seems to be unaffected. (2) The removal of the ovaries in adult animals leads to fibrous degeneration of the uterus and Fallopian tubes, most marked in the mucous membrane. The animals' health remained good. (3) The removal of the uterus in a young animal has no influence in preventing the further development of the ovaries. (4) The removal of the uterus in an adult animal does not give rise to any degenerative changes in the ovaries if the vascular supply of the latter remains unaffected. It will be seen that the conclusions agree with those drawn from the results of surgical operations on the human subject. R.

NOTICES TO CORRESPONDENTS, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

N. E.—The course has already begun. The lectures are given on Thursdays, at 5 p.m., at the Mount Vernon Hospital, in Fitzroy Square, and are free to medical men. The next lecture is to-morrow, and it is given at Fitzroy Square by Dr. G. F. Johnston, on "Pneumococcal Infection."

J. P.—We cannot consider the matter in the light you put it, as the other circumstances put a different complexion upon it. We have not the full details, but our judgment, for what it is worth, would be that active steps can and should be taken.

Surgeon, N.B.—It is a matter for private arrangement before an arbitrator. We cannot possibly deal with it in our columns. It is essentially private, and it would never do to discuss such a matter *coram publico*.

THE CRUSADE AGAINST VERMIN. WHO SAID RATS?

To the Editor of The Medical Press and Circular.

Sir,—

Cancer we think an awful curse,
Tuberculosis tenfold worse,
But cancer sometimes brings a fee
To someone else (if not to thee).
(Our blessings in disguise we see.)
A mine of wealth Appendicitis,
Adenoid growths and Prostatitis.
Now plague produced by rats and vermin
Will form the text for many a sermon.
If everybody lived in flats,
And kept a cat, there'd be no rats;
They'd find such policy to pay,
And all the rats would "flee" away.
But if all rats and mice were dead,
Some other plague would start instead;
Try and get *that* into your head.

Yours, etc.,

London, W. A. D.

DR. SALEEBY AND THE TREATMENT OF CANCER.

A letter of considerable length reached us as we were "at Press" from the pen of Dr. Saleeby, in response to the challenge contained in previous issues of this journal. The length of this communication, and its late arrival, precludes our being able to find space for it in our present number, but we hope to publish it in our next.

M.D. (Motors for Medical Men).—Your letter is unfortunately crowded out "at press"; it will appear in our next.

Dr. O. C. Gruner (Leeds).—See reply to M.D.

Biblical References to the Plague.—A recent correspondent to the *Manchester Guardian* has pointed out these are numerous, and may be found, as indicated by Dr. George Adam Smith in his "Historical Geography of the Holy Land" (published in 1894), in conjunction not only with the Philistines and their offerings of golden boils and golden mice, but with the destruction of the army of Sennacherib (II. Kings, xix. 35) and the "pestilence after the manner of Egypt" (Amos iv. 10), and elsewhere. These are detailed on pp. 157 of the fourth edition of Dr. Smith's book.

Meetings of the Societies, Lectures, &c.

Wednesday, January 22nd.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. A. H. Tubby: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. A. E. Giles: Displacement of the Pelvic Organs.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Cliniques: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

Great Northern Central Hospital (Holloway Road, N.).—2.30 p.m.: Surgical In-patients (Mr. Stabb); Medical Out-patients (Dr. Horder); Gynæcological (Dr. Lockyer); Skin (Dr. Whitfield); Teeth (Mr. Baly); Operations (Mr. Stabb).

Thursday, January 23rd.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.)

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Lecture:—Dr. T. R. Whipham: Pneumonia in Childhood.

Great Northern Central Hospital (Holloway Road, N.).—2.30 p.m.: Medical In-patients (Dr. Morison).

St. John's Hospital for Diseases of the Skin (Leicester Square, W.C.).—6 p.m.: Lecture:—Dr. M. Dockrell: Paratuberculides (due to Tuberculous Toxins): I., Macular; II., Papular; III., Pustular; IV., Pigmentary.

Friday, January 24th.

Royal Society of Medicine (Epidemiological Section) (20, Hanover Square, W.).—8.30 p.m.: Dr. E. W. Goodall and Dr. H. E. Corbin: Rubella.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. W. Stuart-Low: Clinique. (Throat.) 5.15 p.m.: Lecture:—Dr. G. H. Savage: Mental Disorders of Childhood.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques: Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. M. Leslie).

Great Northern Central Hospital (Holloway Road, N.).—3.30 p.m.: Lecture:—Dr. J. H. Horder: Residual Symptoms after Cerebro-spinal Fever.

Tuesday, January 28th.

Royal Society of Medicine (Therapeutical and Pharmacological Section) (Apothecaries' Hall, Blackfriars, E.C.).—4.30 p.m.: Prof. W. E. Dixon: Arterio-sclerosis and its Causation. Prof. A. R. Cushny: Nutmeg Poisoning.

Appointments.

Girvan, Hugh, M.D.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Maybole District of the county of Ayr.

Harker, T. H., M.D.Lond., Certifying Surgeon under the Factory and Workshop Act for the Harwich District of the county of Essex.

Hudson, Bernard, M.D.Cantab., M.R.C.P.Lond., M.R.C.S., Pathologist and Registrar to the East London Hospital for Children, Shadwell, E.

Hutchinson, J. R., M.B., Ch.B., D.P.H.Vict., Assistant Medical Officer of Health of Manchester.

James, William Morgan, B.A.Cantab., L.R.C.P.Lond., M.R.C.S., Medical Officer for the St. Woolos District

Lapage, C. P., M.D.Vict., Medical Registrar to the Manchester Royal Infirmary.

Price, Ernest Henry, L.S.A.Lond., Resident Assistant Medical Officer to the Cardill Workhouse.

Vacancies.

Lurgan Union (Ireland).—Resident Medical Officer. Salary, £80 per annum, with apartments, laundry, and first-class rations. Applications to James Calvert (Clerk of Union), Workhouse, Lurgan. (See Advert.)

Royal City of Dublin Hospital.—Annual Election of Resident Medical Officer. Immediate application to the Hon. Sec., Medical Board.

Berry Wood Asylum, Northampton.—Junior Assistant Medical Officer. Salary, £150 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent.

Cambridgeshire, etc., Asylum.—Second Assistant Medical Officer. Salary, £120 per annum, with board, lodging, and attendance in the Asylum. Applications to T. Musgrave Francis, Clerk to the Visitors, Cambridge.

London Fever Hospital, Liverpool Road, N.—Resident Medical Officer. Salary, £250 per annum, with board and residence. Applications to the Secretary.

Staffordshire Education Committee.—Medical Inspection of School Children.—Senior School Medical Officer. Salary, £300 per annum. Applications to the Director, County Education Offices, Stafford.

Joint Counties Lunatic Asylum, Carmarthen.—Assistant Medical Officer. Salary, £200 per annum, with board, lodging, washing, and attendance. Applications to W. Morgan Griffiths (Solicitor), Carmarthen.

Borough of Eastbourne.—Assistant to the Medical Officer of Health. Salary, £150 per annum. Applications to H. W. Foyargue, Town Clerk, Town Hall, Eastbourne.

Births.

Nathan.—On Jan. 15th, at 50, Harrington Gardens, London, the wife of Sidney Nathan, M.D., of a son.

Deaths.

Chaplin.—On Jan. 15th, at 65, Wellington Road, London, Joan, the wife of Arnold Chaplin, M.D., aged 43.

Humble.—On Jan. 15th, at his residence, Corfe Castle, William Edward Humble, M.D., aged 87 years.

Simpson.—On Jan. 16th, suddenly, at Sandy Bank, Sidmouth, James Tracy Simpson, M.D. (Major R.A.M.C. Militia), late of Farnborough, Hants, in his 47th year.

Stevenson.—On Jan. 17th, at Sandhurst Lodge, Streatham, Dame Agnes Stevenson, wife of Sir Thomas Stevenson, M.D., F.R.C.P., aged 68.

COPYRIGHT

Thirty years of Supremacy.

Ever since PARKE, DAVIS & CO. introduced CASCARA SAGRADA to the medical profession in 1877, their preparations of the drug have been preferred because of **uniform activity and greater therapeutic efficiency.**

The preparation which is recognised as the standard, the world over, is the original, bitter

FL. EXT. CASCARA SAGRADA (P., D. & Co.)

DOSE :—As a tonic laxative, three to fifteen minims three times a day.

The most efficient and popular of the palatable preparations of Cascara is

CASCARA EVACUANT (P., D. & Co.)

DOSE :—Ten to thirty minims three times a day.

In the course of their investigations, P., D. & Co. discovered that the laxative effect of cascara sagrada was not alone due to its bitter glucoside, but also to the action of a glucoside free from bitterness.

By an original process the latter is separated in a wholly unimpaired condition and constitutes the basis of CASCARA EVACUANT. This bitterless principle stimulates the functions of the liver and the intestinal glands, and gently increases peristalsis, while it differs from other laxatives and cathartics in that its long-continued use is less likely to give rise to ill effects.

The *British Pharmaceutical Codex* (p. 221) states that the conversion of the bitter principle into less bitter salts by treatment with alkalies is the basis of most "tasteless" liquid extracts, and adds—"but simultaneous loss of activity occurs." *No* alkalies are employed in the preparation of Cascara Evacuant.

Other "P., D. & Co." preparations of CASCARA SAGRADA are:

FLUID PREPARATIONS.

FLUID EXTRACT CASCARA SAGRADA (No. 117).
Formula of 1887, almost free from bitterness.
FLUID CASCARA SAGRADA AROMATIC (No. 536).
FLUID CASCARA SAGRADA COMPOUND (No. 552).
CASCARA CORDIAL.
ELIXIR CASCARA SAGRADA (No. 35).
ELIXIR CASCARA SAGRADA COMPOUND (No. 36).
ELIXIR CATHARTIC COMPOUND (No. 38).

PILLS.

CASCARA SAGRADA EXTRACT.
1 grain, 2 grains, and 3 grains in each.
ALOIN, STRYCHNINE and BELLADONNA CO. (No. 29).
ANTI-CONSTIPATION (Nos. 49 & 50).
CASCARA SAGRADA and NUX VOMICA (No. 154).
CASCARA, NUX VOMICA and BELLADONNA (No. 155).
CASCARA COMPOUND PELLETS (No. 150).
FERROUS CARBONATE and CASCARA (No. 888 & 889).

TABLETS.

CASCARA SAGRADA EXTRACT, 1 grain, 2 grains, 3 grains, and 5 grains in each.
ALOIN, BELLADONNA, STRYCHNINE and CASCARA (Chocolate-coated, No. 13.)
ANTI-CONSTIPATION (Sugar-coated, No. 9; or Chocolate-coated, No. 19).

Also POWDERED EXTRACT OF CASCARA SAGRADA—CASCARIN—CASCARIN GRANULES—CASCARIN TABLETS.

For formulae and other particulars, see Current Price List.

VOL. CXXXVI. WEDNESDAY, JAN. 29, 1908. No. 5.

NOTES AND COMMENTS.

The *Lancet* Libel Action.

WE need hardly say that the *Lancet* has no sympathetic condolences in the issue of the libel action brought against it by Mr. A. Q. Tucker. We fear that the probability of an adverse verdict was increased by the fact that the writer of the comment did not speak "by the card," for he assumed that Tucker's Specific was advertised in the usual quack manner, whereas it was asserted in court that this was not so. A tempting argument would have been that "if it was not Homer, it was another fellow of the same name," but that of course could not be admitted in the case where a particular person was challenged. We do not attach any importance to the string of "cures" that appeared in court, for as was shown in Dakhyl *v.* Labouchere, no one argues that irregular practitioners do not benefit somebody; the objection to them is that they injure an undue number in the process of getting a few "cures." A qualified man may be a "quack of the rankest species," as we know, so that a mere procession of believers in a remedy is not in point. In the Tucker case, beside the advantage gained by the fact that he did not adopt the quack practice of advertising, the plaintiff had a number of medical witnesses to prove that they used the "specific" in their practices, and such being the case, it became exceedingly difficult to maintain the original accusation in a way likely to convince the court. Indeed, those two points mainly made the difference between a quack and a drug-trader countenanced and protected by the law, even if indiscriminately selling such poisons as cocaine and atropine.

Medical Reform and Medical Practice.

IT is hopeless for medical reformers and the medical Press to attempt to regularise the sale of remedies if medical practitioners do not support them. It is claimed by every second nostrum-seller that his remedy is approved or prescribed by the medical profession, and there seems to be in some cases this germ of truth in the assertion, namely, that a proportion of medical men are too lazy, or careless, or wanting in therapeutic resource, or principle, to bar nostrums from their practice. What can be thought of a medical man's qualifications if instead of prescribing cocaine and atropine for an asthmatic patient, he gives them A.'s fluid or B.'s extract, containing those commonplace drugs? And what good is it for medical men to prescribe it instead of using the ingredients from which it is made? so far as practitioners are concerned, it should be made perfectly clear that a seller of specifics cannot serve God and Mammon. If he appeals to the public who cannot discriminate between good and evil in the matter of drugs, he should forfeit for ever the countenance of the profession. There is nothing vindictive in that. A drug-seller cannot cheat a medical man—at least, he should find it hard to—by claiming undue merits for his wares; he can cheat the public, and it follows almost inevitably, if he appeals to them, that he does so because his stuff will not stand the critical scrutiny of the medical profession; in other words, that it is valueless, or over-rated, or too high-priced, and probably all three.

Sense and Sensibility.

To revert to the *Lancet* case again, we cannot forbear quoting the exceedingly apropos remarks that appeared in the *Pall Mall.* Said that journal, after arguing the legal question, "At the same time, we feel that the public need to be defended from an enormous number of useless and even mischievous concoctions, and much lighter damages would have sufficed to mark the fact that the *Lancet* had gone astray in this case. If there had been malice in the comment, or if it had caused actual loss to the plaintiff, the question of damages would have stood on quite a different basis. All we can say is that the penalty seems to be unduly severe for errors made in the course of an honest attempt to save the public." It is instructive to place alongside that quotation one from the journal which we have described as "perhaps the most persistent reviler of the medical profession that we have to contend with," and which has repudiated the charge. In a leader on the subject, the *Star* observes: "If the case reduces to more modest proportions the affectations of moral superiority displayed by the medical journals in their lecturings to the lay Press, or convinces the public that curative wisdom does not reside wholly and solely in the medical profession, then it will not have occupied the court in vain." The *Star* is what Mr. Chamberlain would call "a good judge" of libel actions, but it has not sufficient generosity to forgive its brother penman an unfortunate slip; it prefers to take an unsportsmanlike advantage of it to attack the medical profession and to defend its own blatant advertisers.

Unfortunate Bonesetting.

THE extraordinary success in the treatment of injuries which we are accustomed to associate with bonesetters and their "bloodless surgery" has, like its poorer and more legitimate sister, surgery, occasional exceptions. Happily for the art which depends for its continued existence entirely on the self-puffs of its exhibitors, the dissatisfaction which occasionally is experienced by sufferers who have resorted to it seldom finds its way into the Press, and the general public have an idea that the bonesetter's career is a triumphant procession from cure to cure. One of these exceedingly rare instances of disappointment came to light last week, and it has a particular interest for us in that we commented on it in these columns at the time it was first in the public eye. The case was that of Birch, a jockey, who sustained at Gatwick an injury to his back, reported to be a fracture of the spine, and who was under the care of a local practitioner and a well-known London surgeon. As in all such cases the illness was long drawn out, and Birch apparently got tired of his inactivity, and being urged by a judicious friend to place himself in the hands of a bonesetter, finally yielded. Two gentlemen of the craft were eager for the opportunity of restoring him to health, Mr. Rabey and Mr. Barker, and eventually victory lay with the former, who captured his prize, and, strongly against medical advice, moved the patient to his "Home" at Highbury. We remember wondering how long it would be before the "cure" was announced, and after fretting our soul with impatience for some months, we had settled down for a long wait.

Double-edged "Advertisement."

UNEXPECTEDLY the denouement came last week in the shape of the report of an appeal against a decision of the Bloomsbury County Court judge, who had tried an action brought by Rabey against Birch, and dismissed it. The point in dispute was whether Birch was liable for £72 for the benefits he had received at the hands of the bonesetter, and the judge said he was not. This view was upheld in the High Court. Although it is not specifically stated, the presumption is that Birch was not cured of his complaint, and the plea put forward by his counsel to the effect that there was no contract because the appellant undertook to treat the defendant to get an advertisement out of the case, is interesting and instructive. At any rate, the parties seem not to have hit it off, and the world now knows that it is not in bonesetters to command success, even if they do all they know to deserve it. On the point of law we should have thought, apart altogether from the defence put up, that it could have been successfully pleaded that the bonesetter had no *locus standi* to bring a case into court to recover fees for medical attendance, although in the ordinary way he might recover for board, lodgings, and so on. It is rather odd that this defence is not raised in cases where irregular practitioners sue for fees, as no other should be necessary where it is relied upon. One of the blessings attaching to registration under the Medical Acts is supposed to be that the practitioner can sue for fees, whereas otherwise he could not. However, Mr. Rabey seems in this case to have burned his fingers, and with his rivals advertising for all they are worth, he will have some lee-way to make up.

Battalion Chiropodists.

THE luxuries of to-day are the necessities of to-morrow, and modern life has an insatiable maw whose appetite seems to grow by what it feeds on. Manicure and chiropody have hitherto been regarded as luxuries for the wealthy who wished to be relieved of the trouble of trimming their nails and cutting their corns, but now the latter art has been placed by a generous War Minister at the disposal of the private soldier, and a class for instruction of non-commissioned officers and men in chiropody has been formed at Queen Alexandra's Military Hospital, Millbank. As the course is to last twenty-four days we fancy that there must be more in the mystery of chiropody than meets the mere surgical eye, that is, unless chiropody is an innocent sounding name for the surgery of the foot, and the instructed soldiers are to go forth to remove hammer-toes and ingrowing toe-nails from the feet of their less fortunate brethren in the ranks. Perhaps after twenty-four days they will be capable of even more heroic procedures. But it is a little puzzling to consider what rank the chiropodists will hold. We understand they are to be called "Battalion chiropodists," but do not gather if this carries with it a definite status. Perhaps they will remain in the ranks, and their chiropody will be merely an extra accomplishment, like marksmanship or riding, leading to a badge and an increase in pay; or perhaps they will become "specialists," and when they leave the service set up as "Foot- hygienists" or corn-curers, or in some similar line. We know, of course, the trouble that officers have with men who suffer from sore feet, but, after all, is not the boot-contractor the person to reform—or perhaps the system of contracting for boots in bulk? One cannot help wondering if the Tommy of the future is to have his nails polished for review day by the battalion manicurist, his moustache waxed by the battalion hair-dresser, and his teeth scaled by the battalion dentist.

LEADING ARTICLES.

THE LEGAL POSITION OF UNQUALIFIED MEDICAL PRACTICE.

VARIOUS recent decisions in the Law Courts have brought the matter of qualified medical practice into prominence. In some ways the mulcting of the *Lancet* for castigating an American proprietary article for the "cure" of asthma, bronchitis and consumption is the most notable. Medical men, who are wont to regard most forms of asthma and bronchitis as purely sympathetic, will learn with consternation that a man without medical training may now advertise with impunity a single nostrum to cure the maladies mentioned. The verdict is to be appealed against, so that further comment on the case at this stage is undesirable. At the same time, it may be remarked that the evidence brought forward at the trial to the effect that many medical men in the United Kingdom recommend the asthma "specific" to their patients reveals a deplorable lack of ordinary wisdom and prudence on the part of the profession. If these gentlemen were not actually aware of the composition of the nostrum, they may now learn through the medium of the newspaper reports that they have been ordering their patients a strong solution of sulphate of atropine, together with a little cocaine, some antispasmodic of the nitrate group, and other apparently more or less sweet substances. The unhappy persons who acquire a passion for the use of the remedy are probably in the grip of a drug habit. Quite apart from the merits of this particular case, the indiscriminate sale of deadly drugs under the disguise of a patent medicine label can hardly be depended on as conducive to the best interests of the public. The plaintiff, who is styled in the *Times* report under the extraordinary description of an "osteologist," which we take is used as a synonym for "bonesetter," appealed in the King's Bench Division against a nonsuit in the County Court rejecting his claim for £72 2s. alleged to be due to him for attendance and nursing. The plaintiff, a jockey, resisted the appeal successfully. The point as to whether recovery could legally be made by a medically-qualified person for medical attendance does not appear to have been seriously raised, and the case was settled upon the question of the presence or absence of a proper contract. This seems an anomalous position when we reflect that even a duly-qualified man has not the power to receive fees in court unless he has been registered as well as qualified. Far less, then, would it be imagined that an unqualified person should be able to recover fees for practice which he is legally not qualified to perform. Possibly it is legal for any unqualified person to enter into a contract to render certain specified services to a second party on certain terms, even though those services be of such a nature that only registered medical practitioners, acting as such, would be able to recover by legal process. In any event the situation appears farcical, and the sooner the defence unions take steps to get a clear judicial utterance upon the point the better for the medical profession. It is intolerable that an unqualified person be permitted to recover payment for medical attendance where a properly qualified (but unregistered) practitioner would be debarred from any such action. The importance of this matter to the medical profession is considerable, inasmuch as there is hardly any branch of practice which is not encroached upon by the unqualified pretender. Finally we come to a death which is alleged to have taken place after the injection of cocaine into the gum of a patient by a dentist who had no legal professional status in the United Kingdom. The particular case is still under investigation, and we can therefore offer no opinion. At the same time, a few remarks may be made upon the general question involved. We have before now pointed out the extreme danger incurred by any person who, not being medically qualified, administers a local or a general anæsthetic. The occurrence of death under an anæsthetic is at any time an extremely grave affair. Its circumstances, however, become infinitely more complicated when the medical skill of the administrator is not vouched for by the tests demanded by the State for the protection of its subjects. Humanely speaking, it is hard to understand the temerity of mind of any unqualified person who, under such circumstances, is prepared to risk a charge of manslaughter by the administration of an anæsthetic.

CURRENT TOPICS.

The New Medical Officer of Health to the Local Government Board.

The appointment of Dr. Arthur Newsholme to the Medical Officership of the Local Government Board in place of Mr. William Henry Power, marks a new departure in that particular branch of the Civil Service. For many years past the new Chief Officer has been known as the energetic Medical Officer of Health of Brighton, and as a distinguished worker in many branches of State medicine. Mr. John Burns has doubtless reasons satisfactory to himself for going outside the many distinguished men who are at the present moment to be found on the medical staff of the Local Government Board. In the natural order of things the successor to Mr. Power would have been chosen from among the existing staff. As things go, there is little doubt that Dr. Newsholme will find himself received with that spirit of loyal and unselfish co-operation that has always been a special characteristic of the department. Indeed, it is only with a full conviction of the existence of such loyalty that one could view the situation without some qualms as to the future. As it is, a brilliant career may be anticipated for Dr. Newsholme in the office that has been rendered illustrious by the labours of such men as Simon, Buchanan, Thorne Thorne and Power, who have done much to render the department one of the most important in the State.

Medical Men and the Births Notification Act.

The medical men of Aberdeen are up in arms against the Notification of Births Act. Last week they sent a deputation to explain their views to the Town Council, and to ask them to delay their adoption of the matter until an opportunity had been afforded for the amendment of the Act. Their spokesman was Dr. Williamson, President of the Aberdeen Medico-Chirurgical Society. He said the medical profession was ready now, as it had always been, to support the Public Health Department in everything where they thought it was for the benefit of the community, but they objected to being coerced under the threat of a penalty to do anything which they believed was not only unnecessary, but which they thought would be of absolutely no gain to the public, and which would be certainly contrary to the strongly-expressed desire of a section of their patients. The memorandum submitted with the unanimous approval of the Society will be found elsewhere (page 134) in the present issue. The chief objections raised were that the proper person to notify was the husband or the friends of the patient; that the Public Health Department would gain nothing by having their information from medical men; that to notify births would be to betray professional secrecy; and, finally, that the service was unremunerated.

The Fees of Friendly Societies.

The dispute between the Alfreton medical men and the local friendly societies is worthy the attention of the profession. At present there does not appear much probability of a settlement of the matter on one side or the other. The medical men at first demanded four shillings all round for medical attendance on the lodge members, but we understand that they have modified their terms by offering to accept 3s. per head for juveniles. The clubs considered those fees too high, and suggested three shillings and sixpence for adults and three shillings for juveniles where the members are not provided for from other sources; three shillings for adults who are provided for in other clubs; juveniles free up to thirteen years, and two shillings per head from thirteen to the years when they are provided for. It is stated in the local newspapers that the clubs are determined; if there be no settlement, they will proceed to establish a medical aid association and employ their own medical officer. In arriving at that decision it is to be presumed they have made themselves acquainted with the pros and cons of the case from the legal, social, ethical and professional points of view. The fact that the members of a learned profession should be forced to accept such paltry fees as those in question is in itself an unmistakable evidence of the great lack of organisation in their ranks. However, the fact that they have taken a determined stand is reassuring, and with the help of the profession generally, not to mention the medical journals and the General Medical Council, there may yet be a happy issue out of present troubles.

Is Dublin Dirty?

We understand that certain members of the Dublin Municipal Corporation have taken exception to an editorial note which appeared in our issue for Dec. 4th, on the dirty condition of the streets in Dublin. We further understand that the article in question has been referred to a committe for report. We may say at once that we shall be most pleased if our comments are proved to be inaccurate, because it is a most unpleasant thing to live in a city which merits such a description. It is, however, equally unpleasant to live in a fool's paradise, in which we see dirt through the rosiest of glasses. It is bad to be dirty, but it is worse not to know that we are dirty. Knowledge of our faults tends to promote reform; ignorance of them to promote their perpetuation. If Dublin is a clean city, how is it that it possesses an abnormally high death-rate, and how is it that almost every stranger who comes into it is struck by its dirt? We are afraid that no one outside the Corporation of Dublin will disagree with the view of such visitors. At the same time we do not suggest that the Corporation do not spend a large amount of time and an immense amount of money in trying to promote cleanliness, although for some reason or other their efforts do not bear the fruit which might reasonably be expected from the cost. It may be suggested that a large number of the workmen in the City Cleansing Department are physically unable to do what is usually considered a full day's work? We have seen many such at work in the streets who gave us this impression, but if these have not passed their work, then it is time that they were dismissed for laziness.

Sentiment, Sleeping Sickness, and Influenza.

It is curious to note how the human mind is apt to be swayed by sentiment even in the most direct issues of life and death. Tell them of sleeping sickness, that remote malady with the attractive name, or malaria, or any other far-away tropical scourge, and straightway they become filled with the strong wine of human philanthropy, and fit out expeditions and send off the cream of our scientific mankind to fight the foe in his native lair. Yet we have bacterial diseases no less deadly killing our fellow-countrymen here at home. Take influenza, which, for years past, has killed scores of thousands, and which is now sweeping over the country in a fresh epidemic wave. Why not endow our laboratories and employ our best medical brains to stamp out influenza, the microbe of which was recognised a dozen years or more ago? Would it not be a good investment for the Government to spend, say, a million pounds—a sum less than the cost of an ironclad —to find out a cure for influenza, or at least some method of prevention? Let the good folk who give their money to treat the natives of foreign countries be reminded that charity begins at home, and that there are scores of deadly home diseases, such as measles, scarlatina, whooping cough, and influenza, which could be most assuredly vanquished by a properly-endowed system of national scientific research.

The Prevention of Hospital Abuse.

The Board of Management of the Royal Victoria Hospital, Belfast, has just concluded a series of conferences with their medical staff on the subject of the treatment of patients in the extern department of the hospital, with the object of preventing hospital abuse. The first result has been an alteration of the by-laws governing the privileges of subscribers as to the admission of patients. Annual subscribers of a pound can now recommend one intern and two extern necessitous patients for admission. Formerly the word "necessitous" did not appear. The second result is the alteration of the rules for the admission of patients by inserting the words "of the working classes" after the word "patients." Thirdly, a circular has been issued to the working men and women of the city and neighbourhood inviting them to contribute regularly to the funds of the hospital, and offering certain advantages to works from which regular contributions come. These are as follows:—(1) Every subscriber of the working classes employed in the works will be admitted free as an intern patient; (2) any member of a family (not being a wage earner) whose father is a subscriber will be admitted free; (3) any youth who is a subscriber, and who is the support of his mother or other members of the family, will be entitled to the same advantages for them as if he were the head of the family; and (4) every subscriber (of the working classes) or member of his family (not being a wage earner) will be eligible for extern medical advice or surgical treatment free of charge. Lastly, a notice is to be hung in the extern department stating that advice is only for those who are unable to pay for it elsewhere. Whilst quite recognising the importance of this effort to prevent hospital abuse, we are afraid that the proposal relating to regular contributions will entirely vitiate the effect of the other proposals. The fact that a contribution of pennies has been made by an individual to the funds of the hospital under certain conditions will, we fear, render it impossible to prevent his or her admission subsequently on the ground that they are not necessitous.

Inconsistency in Medical Practice.

We are accustomed to flatter ourselves as a profession on our knowledge of modern hygiene, and on the progress which the community is making under our instruction. We all believe in the virtues of cleanliness, of fresh air, and of exercise. In the treatment of our patients we carefully regulate these matters, and a physician who in these days would treat a case of phthisis by the "close" method of a generation ago would rightly be regarded by his fellows as little short of a criminal. It is often said, however, that a doctor makes a bad patient. And in regard to preventive medicine as to curative, the medical man often fails to apply his own precepts to himself. In an article in the current number of the *British Journal of Tuberculosis*, Dr. Leonard Williams rightly calls attention to our inconsistencies in this respect. The physician who instructs his patient carefully in the virtues of fresh air, often furnishes a shocking example by his stuffy consulting-rooms, with its heavy hangings and closed windows. We have often looked at the rows of bedroom windows in a street of professional residences, to see them hermetically sealed, or showing a chink of a few inches. Which of us has not observed the thick and uncomfortable atmosphere which so commonly prevails at medical meetings, and the horror created at the opening of a window by some one of bolder spirit than the rest? These matters are of considerable importance, for until medical men show the way by example as well as by precept, they can hardly wonder if the public is inclined to look with suspicion on their advice.

Medical Incomes.

Nothing is more certain than that the possession of the highest standard medical degrees and qualifications does not necessarily pave the way to fortune. So far from that, many a man who has had a brilliant university career is doomed to spend his life in the drudgery of poorly-remunerated labour and mean and sordid surroundings. It would be well if medical aspirants recognised more generally than is at present the case that in all cases it is desirable to have a certain sum of money wherewith to purchase a practice, or otherwise to enable him to tide over the years of inevitable waiting. The newly-qualified medical man, who has spent all available funds in an expensive training, may look forward, as a rule, to a prolonged encounter with hard times. A settled income of £500 a year is so much of a prize as to cause the keenest competition amongst a large number of candidates. The rush of men bearing distinguished credentials for any fairly-paid post, such as that of medical officer of health, or the superintendency of a lunatic asylum, is simply pathetic. When will the public awaken to the injustice they are doing to the body of honourable, hard-working, highly-skilled men in their midst, whom they are deserting for the quack and the charlatan, for the bonesetter and the herbalist, for the dispensing chemist and the patent medicine vendor. As against the poverty of the learned man of medicine may be placed in sharp contrast the huge fortunes piled up by nostrum vendors who are ignorant of the medical art in any true or extended sense. Only a short while ago it was stated publicly in court that the profits arising from a single so-called "*cure*" for a symptomatic complaint amounted to no less than £17,000 a year. That represents just forty-two medical practitioners at an average of £400 per annum. The irony of the situation is, that the formulæ of the nostrums are derived from medical research, while the sale is begotten of brazen advertisement.

Poison in Cough Lozenges.

The trade in proprietary medicines is capable of being controlled in various directions, were existing laws put into action by the authorities. Not long ago the City of London Coroner called attention to a case in which a person was in the habit of taking certain cough lozenges. It was stated by a medical witness that they probably contained opium, and the foreman of the jury added that those particular lozenges were sold in every street in the City. Now, if that were the fact, every vendor of lozenges containing opium is liable to a prosecution under the Sale of Poisons Act. A common ingredient of cough lozenges is chlorodyne, which contains, among other drugs, chloroform and morphia. Chlorodyne is a proprietary medicine containing one or more of the scheduled poisons, and not being a "patent" medicine, falls within the Act. Lozenges containing chlorodyne must accordingly also fall within the statutory regulations, and any person selling that preparation except under the label "poison," and without an entry in a properly kept book of the name and address and signature of the purchaser, and the purpose for which the poison is required, is liable to penalty. It is most desirable that all cough medicines of any kind whatever should be analysed, and if found to contain scheduled poisons, that they should be brought at once under the control of the Sale of Poisons Act. Many infants and children are killed year by year by the administration of "soothing" nostrums containing deadly narcotic drugs. It is simply farcical to endeavour to protect infant life by a Notification of Births Act while we permit the young of the nation to be decimated by poisons vended under the spurious guise of curative medicines. A little vigorous co-operation between the police and the local sanitary authorities would soon put an end to a good deal of the mischief. Even the most ignorant mother would hesitate before she dosed her baby from a bottle decorated with a red poison label.

PERSONAL.

Sir William Ramsay, F.R.S., will open a discussion on "River Pollution" at the Royal Sanitary Institute, on Wednesday, February 12th, at 8 p.m.

Dr. Lewis C. Bruce is delivering the Morison Lectures at the Royal College of Physicians of Edinburgh on the alternate days of this week.

Sir George T. Beatson, K.C.B., was entertained at a complimentary banquet on January 10th at Glasgow, to celebrate his recent honour. The Duke of Montrose was in the chair.

The annual dinner of the West London Medico-Chirurgical Society will be held at 7.30 p.m., Friday, February 13th, at the Hotel Great Central, the President, Mr. R. Lake, F.R.C.S., in the chair.

Dr. Frederick Rose will read a paper on "The Physical and Educational Aspects of the Open-Air School" at a meeting of the Medical Officers of Schools Association on January 30th, at 3.45 p.m.

Mr. Gerald E. Friend, B.A., Oxon., M.R.C.S., late House Surgeon and House Physician to St. George's Hospital, Hyde Park, has been appointed Superintendent and Resident Medical Officer to that hospital.

Mr. John W. Dowden, F.R.C.S.Ed., has been asked to take charge of the late Professor Annandale's wards at the Royal Infirmary, Edinburgh, and to carry on the lectures of the Chair of Clinical Surgery till the close of the winter session.

Sir Dyce Duckworth and Mr. Thomas Bryant have been re-elected to represent the Royal College of Physicians of London and the Royal College of Surgeons of England respectively on the Council of Queen Victoria's Jubilee Institute for Nurses.

The Finchley District Council have appointed Dr. G. C. Taylor, the Medical Officer of Health, to carry out the medical inspection of school children, at a salary of 100 guineas per annum. They also adopted the Notification of Births Act, and agreed to appoint a lady health visitor, at a salary of £80 per annum.

A CLINICAL LECTURE

ON

MODERN THEORIES OF DIET IN THEIR RELATION TO PRACTICE. (a)

By ROBERT HUTCHISON, M.D., F.R.C.P.Lond.,

Physician to the London Hospital, Assistant Physician to the Hospital for Sick Children, Great Ormond Street.

[Specially Reported for this Journal.]

Gentlemen,—I have chosen this subject to-day because it is one in which I have, for some time, taken considerable interest, and partly because I feel that we still, as a profession, do not attach as much importance to diet as a method of treatment as we ought. That is attributable to various causes, one of which probably is that the medical student is not taught it; consequently men, when entering practice, do not regard it as so important as, for instance, drug treatment. But probably there never was a time when more interest was taken by the laity—especially the educated laity—in the question of dietary, so that almost every patient one sees, in certain classes of society, has his own views on the matter; and it is important that we should be able to meet these people on their own ground, to discuss with them, if necessary, dietetic theories in which they are apt to be posted, owing to the fact that the daily Press devotes so much space to questions of that sort. And one cannot do that without having a physiological basis to go upon, and so I must ask you to allow me to be rather theoretical at the outset, to consider the physiological basis to which all diet theories must be referred, and to which they must conform if they are to hold good.

The physiological basis of diet depends upon two great objects—(1) the conservation of body energy; (2) the conservation of body substance. Food is the income side of the balance-sheet, and therefore the material for the conservation of body substance must come out of the food. These two lines have to be kept clearly apart in discussing dietetic theories, because some theories refer to material, and some to energy. The total expenditure of energy in the body means the amount of food required to maintain the body in a state of balance. On that point we have, from physiology, fairly definite lines to go upon. Calculated in heat units, and taking the ordinary individual, 3,000 calories is the amount of energy contained in the diet of an ordinary individual of average weight and height who is doing an average amount of work. That is easily determined, as it is merely a physical question. There are some people who would have you believe that the principle of the conservation of energy is suspended in the body, and that people can do work on an insufficient amount of food. They cannot have grasped the fact that the amount of energy taken in must correspond to the amount given out. The number of calories varies with individuals and with circumstances; and those circumstances are important, because they make it impossible for a doctor to know exactly how much any individual ought to eat. There are many people who are dissatisfied if you cannot tell them how much, to an ounce or two, they or their children ought to eat. You cannot do that in the case of individuals; you can only say that 3,000 calories applies to an average person. It depends on the age, sex, size, build, and so on. It depends on age, because, within certain limits, the young body is the abode of young inhabitants—in other words, young and active cells—and they use a greater amount of energy. Therefore, young people require more food than do older people. And women require less food than men, probably because their muscles are smaller. Again, the person who has proportionally a large amount of muscle will require more food than one of the same weight who is merely fat, because fat is so much dead weight and is scarcely alive at all. It depends also upon the shape or build, tall, thin people requiring more than short, stout ones, the former having a greater amount of surface from which heat is lost. It is these considerations which explain the anomaly which puzzles many lay people, who say that So-and-So eats a lot but remains thin, whereas So-and-So eats sparingly and yet keeps stout. The amount of work done has a more profound influence than anything else on the total expenditure of energy in the body. Climate has less influence than is often supposed. In cold weather you do not need to eat more than in hot, but the food can often be digested much better. One of the most important things of all is the influence of temperament on the expenditure of energy. The cells of some people seem to be more active and alive than those of others, and so they require to take in more. I have sometimes wondered whether that may be due to variations in the activity of the thyroid. In Graves' disease people have a temperature running up above the normal; they perspire easily, and remain thin. In myxœdema, when the thyroid is inactive, the converse is true. There may be people who are not the subjects of Graves' disease, but have active thyroids, and they require more food than others. Others are not the subjects of myxœdema, but their thyroids are not so active, and they tend more readily to put on fat and require less nutriment. This makes it all the more difficult to dogmatise as to the amount of nutriment required by any one person.

Now as to the other side of metabolism, the conservation of body substance, the preservation of the body intact without losing weight. That is a matter upon which physiologists cannot give us much information. This is unfortunate, because what we need most of all just now is information about the nitrogenous waste in any given space of time. Physiologists have had to fall back on the rough-and-ready method of simply calculating how much nitrogenous material people consumed in 24 hours when in a state of balance. That is how Voit originally got his standard, arriving at 4½ oz. of protein as the amount required in 24 hours by the average individual. Americans particularly have said that that figure is far too high—that less than half that quantity will do. Chittenden, by carefully devised experiments applied to many individuals, showed that in the conditions in which these individuals were living, it was possible to maintain the balance of tissue by only taking half that quantity. And other people, taking up his results, say this is what everybody ought to do; we are eating far too much protein. I will consider that presently. Meanwhile, we can do much towards the solution of this question by watching the effects of diet upon patients.

Now with regard to some of the dietetic theories or systems which you will find people adopting or advising other persons to adopt, and which one finds to have been adopted by patients, sometimes with disastrous results, sometimes with more or less success. According to one theory, *our average intake of energy is too high*; practically stated, it means that we eat too much. From a physiological point of view, how do we know whether a person is eating too much, or not? I only know of one way, and that is when the weight is continually on the increase. If you take in more energy than you give out, it is obvious that you must store it in some form—namely, as fat. Unless that is the case, you have no right to say of a person that he is eating too much. The only way out of that dilemma is to assume—and it is a fair assumption—that many people are carrying about a far greater body weight than is necessary. What is the advantage of body fat? That is not easily answered. We know it serves to keep the body warm to some extent, and as a reserve of nutriment. In the case of pre-historic man, it was a great advantage to have a reserve of fat. But under modern conditions such a reserve may be simply an inconvenience. I would like to hear from practitioners present whether they have noticed that patients' ability to stand bad illnesses is in proportion to their body weight. Is it an advantage or a disadvantage for a patient to be stout? It has been said that such people have a reserve of nourishment to draw upon in an illness; but I think it is difficult to substantiate that, because most people can take milk in illness, and that provides quite enough energy. And if you carry about a stone or so more than you need, that increases your muscular work considerably; there is not only the transport of that extra weight from place to place, but it throws on the organs of assimilation a good deal of unnecessary work. If that is so, what is the optimum degree of fat? To that question I do not think it is possible to reply in the case of any individual. A man must find out at what weight he feels. Amongst the symptoms often exhibited by people who try to maintain a greater body weight than is necessary are those which may be described as "biliousness" or "bilious attacks," and many of these people lose their biliousness if you reduce their body weight a stone or half a stone. It is a method which is always worth trying. But it is a disadvantage to have too low a level of body weight, because it renders a person liable to certain diseases, especially tubercle. I always remember a lady who was one of the "faddy" people, and who restricted herself to one meal a day. She carried her theories to such an extent that she became almost a walking skeleton. I saw her some time afterwards, and found that both her lungs were stuffed with tubercle, and she quickly succumbed.

(a) Delivered at the Prince of Wales' Hospital, Tottenham, on Thursday, January 9th, 1908.

With regard to the second system or theory, there are people who maintain that *the amount of repair material is too high*; these are the followers of Chittenden and his school. That means that people eat too much meat, because meat is the food which contains most protein. But I deny that we eat more meat than our ancestors did. Social history shows that we eat far less, especially in the upper classes. In this matter we have no physiological evidence to guide us. Chittenden tried to see how far he could go without the subjects of experiment losing nitrogen. That is an experiment which the human race has been making for centuries, and there is much to be said for the view that if you find huge masses of people have hit upon this quantity of protein, it is presumptive evidence that it is right. At any rate, it should not be lightly set aside. Chittenden is not a doctor, but a physiologist, and we must keep our eyes open to the disadvantages of his system. It is claimed that on half the quantity of meat you give the kidneys less to do, and—with less reason—that you lessen arterial degeneration, and that you get rid of "gouty" symptoms. Chittenden cured himself of bilious attacks and migraine by his system. But we have to beware lest we tumble into the whirlpool on the other side, because there may be dangers in too small a protein intake—that is, in eating too little meat. There is no question that herbivorous animals are more subject to tubercle than are carnivora, and that disease is rampant in Ireland, where a large part of the population is habitually underfed, especially in regard to animal food. Consumptives also seem to have a dislike for meat. The risk of lowering the resistance to disease by taking too little protein may be greater than the risk of overworking the excretory organs by eating too much. Carnivorous animals do not overwork their excretory organs; neither do Esquimaux, who live mainly on animal food.

Vegetarianism hangs very much on what I have said about the views of Chittenden. It is primarily a religious belief or cult, and it is only recently that people have tried to justify it scientifically. If you require the usual amount of protein, the vegetarian diet needs to be so bulky that it may bring on dyspepsia. But if it is true that we should eat about half the protein we do, there is not the same objection to vegetarianism. In practice, vegetarianism is good in the cases in which the system of Chittenden is to be recommended.

The next theory we have to consider is the *lacto-vegetarian theory*, or the theory of uric acid intoxication. It was introduced in the eighteenth century by Combe, and has lately been advocated by Dr. Haig. It assumes that purins, of which uric acid is the best known example, are specific poisons, and give rise, according to Haig, to gout and many other diseases. He asks us to discard all foods containing purin, such as meat, tea, coffee, and so on, and he would confine us to a diet of vegetables, eggs, milk, and cheese. Experiments show that you may ingest large quantities of uric acid deliberately without any special symptoms. But there are some people who have a difficulty in dealing with purins, and for them such a diet is good. Several chronic conditions are benefited by it, such as chronic gout, and migraine, and other paroxysmal neuroses; some skin diseases, such as chronic eczema; also chronic diarrhœa, and some forms of neurasthenia. I think the benefit of the diet is due to the fact that there is very little intestinal putrefaction from it. Milk is one of the best intestinal antiseptics. But if persevered in for a long time, this diet tends to cause dyspepsia.

The last theory is an ingenious one which has been put forward by Dr. Francis Hare. He calls it *the theory of "hyperæmia."* He does not say we consume too much protein, but too much carbonaceous material, such as carbo-hydrates and fat. He has elaborated his views in two able volumes entitled "The Food Factor in Disease." As the author himself admits, there is no chemical proof of the theory at all. He says if you take more carbonaceous food than you can comfortably break down in the body, it accumulates there in some form, but not fat because the people he talks about are not gaining weight. He says it circulates in the blood, and produces a number of diseases, but he cannot say what form it circulates in. You can treat many cases more successfully by Hare's method than by Chittenden's. The diet he gives consists of 8 to 12 oz. of meat, 1½ oz. of bread, a little butter, green vegetables, tea and coffee. People, of course, lose weight on that. He subsequently gradually adds carbo-hydrate until the patient just maintains his body weight, and leaves him on that. By that means, he says, the person gets rid of the excess of this unknown substance. The diseases, again, which are said to be cured by this, are all forms of biliousness, and particularly migraine, cases which are described by Eustace Smith as "food fever," particularly in young subjects, who show a dirty tongue and mild fever. He says it also cures paroxysmal neuroses, such as asthma. I can confirm Hare's statement that such a diet often cures obstinate migraine.

Now it is a striking thing that all the systems I have mentioned profess to cure the same conditions. I think there are two possible explanations of that common mode of action. They may all act through the intestine; possibly by diminishing intestinal putrefaction.

There is another possibility, and that is, that there are more people than we know who have difficulty in completely oxidising nitrogenous matter—I put it in the broadest way—and that incompletely oxidised material circulates in the blood, causing different forms of disease. You may ask, how, then, will cutting down only their carbonaceous material help them? The explanation may perhaps reside in what is called the doctrine of "protein-sparers." If you have a cell, and into its neighbourhood you bring molecules of sugar and fat and protein equally, the one which the cell grasps most easily and breaks down is protein, because it acts less as a foreign body than the others. But if you bring in a huge mass of molecules of fat, then the preponderance makes itself felt in preventing the selection of protein; the cell is bound to turn its attention to what is in greatest abundance. That is what happens in diets which contain not only much meat, but sugar also. Whereas, if you cut down sugar and fat, even if you leave in the protein, the cell is so much more unembarrassed by the other things that it can combust the protein completely. So it does not matter whether you eliminate the protein-sparers, or cut out the protein and leave very little to be combusted; it may come to the same thing in the end. In conclusion, I believe that the best system is an intelligent omnivorousism, eating everything which comes handy, but not too much of it. There are individuals here and there who may need to go further, and you may have to cut out particular things from their diet very carefully. But they are not normal people; they are pathological, and their diet must be framed accordingly.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by W. I. de Courcy Wheeler, M.D., F.R.C.S.I., &c., &c., Surgeon to the Mercers Hospital, Dublin. Subject: "General Surgical Technique."*

CLINICAL LECTURES FOR 1908

We have been favoured by promises of Clinical Lectures from the following Hospital Teachers and Post-Graduate Lecturers (in addition to the list published in our issue for the 1st inst.), to whom we tender our best thanks:—

Chas. A. K. Ball, M.D., F.R.C.S., Surgeon to Sir Patrick Dun's Hospital, Dublin.

Frank H. Barendt, M.D.Lond., F.R.C.S., Physician for Skin Diseases, Royal Southern Hospital, Hon. Surgeon St. George's Hospital for Skin Diseases, Liverpool.

Prof. Vilmos Coldziecher, M.D., Professor of Ophthalmology in the University of Budapest.

H. J. Hobart, M.D., Surgeon to the North Infirmary and the City of Cork Hospital.

Thos. S. Kirk, M.D., Surgeon to the Belfast Hospital, Surgeon Royal Victoria Hospital.

Prof. R. Kruse, M.D., Professor of Medicine in the University of Bonn.

Chas. G. Lee, Hon. Surgeon to the Liverpool Eye and Ear Infirmary, Aural Surgeon to the Royal Southern Hospital, Liverpool.

Chas. J. Macalister, M.D., C.M., M.R.C.S.Lond., Lecturer on Clinical Medicine University of Liverpool, Physician to the Royal Southern Hospital.

Alfred R. Parsons, M.D., F.R.C.P., Physician to the Royal City of Dublin Hospital.

Nathan Raw, M.D., B.S., F.R.C.S., Consulting Physician to the Walton Workhouse, Liverpool, Visiting Medical Superintendent to the Mill Road Infirmary, Liverpool.

Richard Travers Smith, M.D., F.R.C.P., Physician to the Richmond, Whitworth and Hardwicke Government Hospitals, Dublin.

Arthur J. Wallace, M.D., C.M., Hon. Obstetric Surgeon to the Lying-in-Hospital and the Hospital for Women, Liverpool.

ORIGINAL PAPERS.

HÆMORRHAGE INTO THE PONS VAROLII AS THE IMMEDIATE CAUSE OF DEATH IN THE ECLAMPSIA OF PREGNANCY, WITH ILLUSTRATIVE CASES.

By NORMAN C. CARVER, M.B.,

AND

JOHN S. FAIRBAIRN, M.B.

The case which forms the basis of this paper was admitted to St. Thomas's Hospital as one of eclampsia with coma; it was treated as such, and the extensive hæmorrhage into the pons varolii, which was the immediate cause of death, remained unsuspected until it was revealed at the post-mortem examination. This unexpected discovery of the nature of the coma in a case which we had considered to be one of the ordinary eclampsia of pregnancy led us to look into the question of the occurrence of such hæmorrhages in fatal cases of eclampsia, and we have thought that our experience in this case, and the results of our investigations into the similar cases already recorded are of sufficient interest to merit discussion before the section.

We will begin with an account of our own case. The patient, who lived in the hospital out-door maternity district, was a primigravida, æt. 24, about five months pregnant. On the evening of March 23rd, 1905, her card was sent up to the hospital as she was suffering from vague pains, and the obstetric clerk on duty visited her, and reported her condition on his return. She was then seen by one of us. Her mental condition was quite good, and she gave a history of loss of appetite, sleeplessness, headache and spots before the eyes for two or three days. There had been no vomiting and no fits. She had noticed nothing abnormal about her urine, and considered that the amount passed had been as usual. There was œdema of the whole body, which was said to have been present for one week, but up to this time she had been able to do her ordinary household work. The uterus reached to the umbilicus and the fœtal heart was audible. The temperature was normal, the pulse-rate 84; the arterial tension was considerably raised. A catheter specimen of the urine was obtained, and was found to contain so much albumin that it became solid on boiling; there was no blood shown by the guaiacum test. The patient was ordered to keep her bed and was given a saline purge, and arrangements were made for her admission to the hospital on the following morning.

On March 24th, at 1.20 a.m. (*i.e.*, about six hours after she was last seen), the husband woke up and found the patient unconscious, and lying on the floor on her face and knees. He said that he had noticed her hand twitching before he had gone to sleep, and that evidently her falling on the floor had wakened him. As soon as he had got her back to bed he came up to the hospital for help. When the patient was seen by one of us about 2 a.m. she was cyanosed and quite unconscious; respiration was shallow and inclined to be of the Cheyne-Stokes type; pulse 84, tension very high; all reflexes were absent, no unilateral symptoms were noticed and no twitching; the pupils were equal and moderately dilated. An ambulance was procured at once, and the patient removed to hospital. On her arrival in hospital the pulse was found to be much weaker, and the respirations to be more markedly of the Cheyne-Stokes character. She was bled from a vein in the arm and 10 oz. withdrawn, and afterwards 4 pints of normal saline solution were infused, but without any improvement, her condition being extremely grave during the periods of apnœa. Rapid dilatation of the cervix was carried out by means of metal dilators, followed by de Seigneux's modification of Bossi's dilator, and a fœtus of about five months extracted by version. The child was living, and gasped for a few minutes after delivery. The patient's condition did not improve in any way, and she died at 7.15 a.m., without recovering consciousness. Unfortunately the specimen of urine obtained before the onset of coma was not kept, and as no other was available it is not possible to give any further details of the examination of the urine.

The following are the notes of the autopsy which was made on the following day by Dr. Powell White:—

There was some anasarca, especially of the lower limbs.

Brain.—There is an extensive hæmorrhage into the substance of the pons, which is greatly torn and disorganised. The hæmorrhage passes up for a short distance into the crura cerebri. The rest of the brain is normal. There is no evidence of disease of the cerebral arteries, nor was any sign of arterial disease found in any other arteries in the body.

Chest.—Both pleural cavities contain some excess of clear fluid. Lungs and heart normal.

Kidneys.—These organs are not much altered to the naked eye. The cortex is pale and fatty, and the pyramids are distinct. The capsule strips easily, leaving a smooth surface. Microscopically, under the low power, many of the glomeruli are seen to be sur-

---

(a) Read before Obstetrical Section, Royal Medical Society, Jan. 9, 1908.

rounded by a ring of connective tissue. Many of the tubules are swollen, and in places the epithelium is swollen and necrotic. In one part of the section the tubules have been almost obliterated by a mass of recent white fibrous tissue. Under a high power the connective tissue which has infiltrated the glomeruli is seen to be rich in nuclei and of recent origin. Numerous young fibroblasts are present. There is extensive degeneration of the epithelium of the convoluted tubules. The cells are greatly swollen, and show evident granular degeneration. In places the nuclei have entirely failed to take up any stain. In a few tubules the cell outlines are no longer visible, and the lumen is obliterated by granular *débris*. The straight and collecting tubules have escaped change. Some fine fatty degeneration was found in a few scattered tubules after special staining. These changes suggest an acute degenerative process following on a slight chronic interstitial change.

Liver.—This organ weighed 50 oz. and was normal in size, shape, and consistence. On the surface and on section it presented some map-like irregular red patches, varying from the size of a crown piece to that of a sixpence, and having a fairly distinct margin. Microscopically, under a low power, numerous blood-containing spaces are seen scattered through the liver substance. The blood spaces are surrounded by fibrous tissue, and are arranged in groups. In the immediate neighbourhood of each group of blood channels the liver cells are flattened and elongated. With this exception the liver cells are normal in appearance. There is slight proliferation of the connective tissue cells along the portal canal and around the larger groups of blood spaces. These groups of blood spaces appear to have an interlobular arrangement, and to be developed in connection with a branch of the portal canal. Under a high power the blood spaces are seen to be bounded by a single layer of flattened endothelial cells surrounded by a definite ring of connective tissue. The contained blood appears normal. There is no evidence of fibrin formation or of the presence of an undue proportion of leucocytes. In places the septa have broken down and the adjacent channels have become confluent. The liver cells in the neighbourhood of the blood spaces are much flattened and compressed, and here and there islets of hepatic cells may be seen completely cut off from the liver substance. In places there has been definite extravasation of blood, and the corpuscles are seen lying free between the liver cells. There is a very large deposit of brown pigment in the immediate neighbourhood of the blood spaces, and for some distance from each group of spaces the cells contain an excess of pigment. The tumours appear to be cavernous angeiomata, and to have been developed by the dilatation of the existing blood capillaries.

Bladder and *ureters* appear normal.

Uterus rises to the brim of the pelvis There are some remains of the membranes in it. The cervix is slightly torn.

The post-mortem examination shows that death resulted from a cerebral hæmorrhage, causing extensive destruction of the substance of the pons varolii. But it also affords evidence in accordance with our view that the case was primarily one of eclampsia. The kidney changes were slight, but quite definitely those of degeneration in the shape of fatty change and necrosis, such as is usually found in eclampsia, and the amount of chronic renal disease is too trifling to admit of its being considered the primary factor in the case. Although the changes in the liver were not distinctive of those found in the toxæmia of pregnancy, the post-mortem evidence is on the whole quite consistent with our interpretation of the case.

The further evidence which we would bring forward on this question is, first, the occurrence of a definite pre-eclamptic stage. When the patient was first seen, she exhibited the signs of impending eclampsia—sleeplessness, spots before the eyes, headache, with general œdema and highly albuminous urine. That the symptoms came on as early as the fifth month is no valid argument against the disease being eclampsia, for during the last few years there have been three such cases treated in St. Thomas's Hospital in the fifth month of pregnancy—*i.e.*, the case under discussion and two others. Also, according to Clarence Webster (1), one has been observed as early as the fourth month by Willis, and Tarnier, out of 52 cases, noticed one at the fifth month. The earliest case we have come across in the literature is one before the fourth month recorded by Pratt (2).

The next point is that, although there is no definite evidence of a fit, there are points in the history very suggestive of their occurrence. There is the husband's statement of his having noticed the hands twitch before he fell asleep, and there is the fact that the patient was found out of bed on the floor. But the absence of fits is no evidence against the case being one of eclampsia, for, as Schmorl (3) says, convulsions are only a symptom of eclampsia, though a most important one, and they do not constitute the disease itself. Many cases have been recorded as eclampsia in which there were no fits. We may give references to a few we have come across. Schmorl (4) records three, including one of Wendt's (5); Labhart (6), Meyer-Wirz (7), Esch (8), Bouffe de St. Blaise (9), and Binder (10) one each.

Further, the cases of a similar nature we have been able to collect form very important evidence of our case being one of a definite group, in which hæmorrhage into the base of the brain is the immediate cause of death in eclampsia. These cases will be quoted later on, and form, perhaps, the strongest argument in favour of our contention.

Lastly, there is the question of an alternative explanation. It is certainly not easy to understand why a large hæmorrhage of this kind should occur in a previously healthy young woman of 24, without disease of the arteries. Three of the other cases we have collected occurred in young women, so that presumably the poison of eclampsia was the determining cause of the apoplexy in them also.

Assuming, then, on these grounds that the case was one of eclampsia, the next point we wish to consider is the occurrence of cerebral hæmorrhage in eclampsia. The changes in the brain in eclampsia are not definite, but it is very common to find small hæmorrhages, generally meningeal, which are usually ascribed to the rise of blood pressure due to the fits, and that this is the probable explanation is shown by the fact that they are generally found to be most marked in those cases where there have been a large number of convulsions. These small hæmorrhages are, however, quite different from extensive apoplexies, which are much more rare. A very brief review of the statistics will show this.

In a large number of cases from the Vienna Clinic analysed by Schauta (11), out of 90 post-mortem cases 10 cases were noted as showing evidences of cerebral hæmorrhage, and of these, in 4 it was termed "apoplexia gravis" and in the others "apoplexia capillaris." Schrieber (12), in 27 fatal cases, notes no large cerebral apoplexy, though there are 4 cases of capillary hæmorrhage. Glockner (13), out of 26 post-mortem examinations, mentions cerebral hæmorrhage as having occurred in three cases, and meningeal hæmorrhage in 1, though no details are given as to size. Schmorl (14), as the result of his examination of 73 fatal cases, says of the cerebral conditions found:—"Out of 65 cases, in 58 changes in the brain were noted in the shape of small, seldom large, hæmorrhages with areas of softening." For the most part he looks on these as thrombotic in origin and as secondary to the convulsions.

The cases to which we especially wish to draw attention are those of hæmorrhage into the pons varolii, or base of brain, as it is such cases which appear to be similar to our own. Occasionally such are found recorded in some of the statistics already quoted, but the details of the illness are not given fully enough to make them of use for our purpose. For instance, in Schauta's paper he records a case of hæmorrhage into the pons preceded by fits, and one of hæmorrhage into the corpus striatum, in which the history was incomplete. The case which appeals most to us in regard to our own experience is one recorded by Pfannenstiel (15), under the title "Apoplexy as the Cause of Death in Eclampsia." It is of special interest to us, as Pfannenstiel was evidently much impressed by his mistake in diagnosis. He says that the case appeared to be one of eclampsia or uræmia, as shown by the deep coma, the absolute insensibility and loss of movements, by the wide inactive pupils, and the high albuminosity of the urine. The possibility of apoplexy was not considered because there was no asymmetry of the face or any unilateral signs, though he states that these may have been present before the patient was seen.

His patient was a primipara, æt. 22, who was admitted to the clinic, in labour and unconscious, with the diagnosis of eclampsia, at 9 a.m. According to her sister, she had previously been quite well in this, her first pregnancy, but for a few days had had swollen feet and severe pain in the back and side. Some four hours before admission, while lying in bed, she had an attack of sickness and a short fit, after which consciousness had not returned. When seen after admission, she was lying on her back with her limbs quite limp; there was œdema up to the knees. The pulse-rate was 68, of medium strength; respirations 44, shallow and rattling. The pupils were widely dilated, equal, and the corneæ insensitive. The fundus was normal, and no change was noted in the small vessels. The face was symmetrical, and the sensibility over the whole body was lost. The urine withdrawn by catheter was barely 80 c.cm., and became solid on boiling, so that the test-tube could be turned upside down; it contained a few casts and some fatty epithelium, but no blood-cells. The fundus uteri was three finger-breadths below the xiphoid, and the fœtal heart was heard two finger-breadths below the navel. The os admitted two fingers, and the membranes were intact. A kolpeurynter was placed in the vagina; a hot bath (30° R.) for half an hour was given, and an icebag was placed on the head. At 11 a.m. there was marked tracheal rattling and the pulse was irregular, so 600 c.cm. of blood, very dark in colour, were abstracted from a vein, and an equal quantity of normal saline solution injected. After this the pulse improved, and the tracheal rattling became less. At noon the condition was again worse, with a small pulse and very shallow breathing; the os was found to be the size of a thaler, so dilatation with the fingers was adopted, followed by rupture of the membranes and version with the bringing down of a leg. Shortly afterwards a male child, well developed and recently dead, was delivered; ten minutes later the placenta was expressed. For a short time after delivery the respirations were deeper, and there was no tracheal rattling; the pulse was 96, regular and stronger than before; and there was no bleeding. The pupils remained widely dilated, and there was no corneal reflex. This improvement proved, however, to be very temporary, for the pulse became feebler and the breathing stertorous, and at 3.15 p.m. the patient died.

The post-mortem findings were briefly as follows:—In the kidneys there was little change to the naked eye; microscopically there was fine granular and cloudy swelling of the epithelium, with here and there necrosis; there were some fine granular coagula in some of the canals. The *liver* showed a map-like pattern, with deep red colouring of the parenchyma, both on the surface and on section. Microscopically there were areas of unstained or poorly stained cells; the liver cells were fatty, and contained blood pigment. In the *brain* there was complete destruction of the left optic thalamus and surrounding parts by a hæmorrhage which had broken through into the left lateral ventricle, with hæmorrhagic softening of the right optic eminence and filling of all the ventricles with dark blood. There were points of blood in the pons; the arteries were normal, except in the neighbourhood of the hæmorrhage. In the optic eminence was a varix the size of a cherrystone, with fresh thrombosis, and microscopically the position of the bursting of this thin-walled sac was recognised. No varices were noted elsewhere in the body.

In discussing the case Pfannenstiel considers that delivery improved matters for a time by lowering the abdominal pressure, and so relieving the blood-pressure. He thinks that the extensive nature of the cerebral hæmorrhage was the reason of the error in diag[illegible] it early compressed large areas of both cerebral tracts, and so no one-sided symptoms were noted, but only total paralysis and deep coma. Probably the thin-walled varix in the left optic eminence, which must be regarded as pre-existent, formed a *locus minoris resistentiæ*, and when the blood pressure was raised in consequence of the first eclamptic attack, it gave way. He considers that the case is shown to be one of true eclampsia by the highly albuminous urine, by the presence of œdema and the usual premonitory symptoms, and by the pathological findings in the liver and kidneys. Except that the area of the base of the brain involved in the hæmorrhage is not quite the same, this case is similar to ours, and bears out the interpretation which we have given of it.

The next case which we have come across is one recorded by Meyer-Wirz (16). The patient was a primipara of 38, with a considerable amount of albuminuria. Spontaneous delivery of a living child had taken place at 5 p.m., and the doctor, when called two hours later, found her unconscious, in deep coma and cyanosed, with a pulse of 100 and a temperature of 37.5° C. The pupils were of medium size and equal; respiration was of the Cheyne-Stokes type. The uterus was contracted, and there was no hæmorrhage. Two grams of chloral were given by the rectum, and oil of camphor hypodermically; an icebag was put to the head, and artificial respiration was tried, but the pulse rate and temperature rose until they reached 160 and 40.6° C. respectively just before the death of the patient. The post-mortem revealed the following condition:—

Brain.—Pia mater œdematous; sub-pial hæmorrhages in the parietal and temporal convolutions of the right side. In the posterior fossa were 30 c.c. of blood-stained fluid. At the base of the brain was a definite sub-pial hæmorrhage, and blood coagula were present on the under-surface of the medulla and round the origin of the vagus. The pons was markedly widened and bulged forward. On taking away the brain, the surface tore through on the left side, and thick blood flowed out. There were blood coagula in the Sylvian fossa, and the lateral ventricles were dilated and contained blood-stained fluid. There were blood coagula in the corpora quadrigemina. On the right side there was a circumscribed hæmorrhage between the corpora striata, almost in the middle line, and the surrounding tissue was softened. The hæmorrhage involved principally the lenticular nucleus and the internal capsule. The caudate nucleus and the cerebral peduncles were free. In the pons was an extensive hæmorrhage, the aqueduct of Sylvius and fourth ventricle being filled with coagula. There was nothing in the cerebellum.

Kidneys.—The capsule stripped easily; microscopically there was cloudy swelling and some parenchymatous change, but no fatty change.

Liver.—This organ was slightly enlarged, and on its surface were some slight hæmorrhages. On section many punctiform hæmorrhages were seen, and small miliary necrosis all over, especially under the capsule.

The next case is one recorded by Maygrier and Chavane (17). The patient was a primigravida of 25, pregnant 7½ months. When first seen everything was normal, and no trace of albumin was found in the urine. On the following day some difficulty in breathing was noticed, and this rapidly increased. The patient was pale, and there was sharp pain in the epigastrium. Nothing abnormal was found in the lungs or heart. Oxygen was given, and a hypodermic injection of ether. In a few hours vomiting and diarrhœa set in, followed by eclamptic convulsions at short intervals without coma. The urine was then examined and found to be solid with albumin. The convulsions continued, and three hours later the patient was semi-comatose, with a pale skin, but no œdema. The urine was dark, appearing to contain blood, and was solid with albumin. Respiration was normal, and the temperature 36.4° C. Labour had commenced, and the membranes were ruptured; the fœtal heart was heard beating strongly. Chloral, chloroform, and oxygen were administered, and later the patient was bled to the amount of 300 gm., and normal saline infused to a like amount. Rapid dilatation by hand was performed, and a dead child delivered by forceps. During this operation artificial respiration was done, but without relief of the cyanosis, although there was some attempt at respiration. There was considerable post-partum hæmorrhage, so the placenta was removed by hand, and an intra-uterine douche given. The patient died suddenly shortly afterwards.

Inquiry afterwards from the friends showed that the woman had come to the hospital about three months previously, when it was found that there was albuminuria, but she then refused admission. The placenta showed six foci of hæmorrhage, but no œdema. A post-mortem examination was made 24 hours after death. There was no œdema. There were signs of old tubercle in the lungs. The heart was enlarged and fatty, with pale muscle, and some old disease of the mitral valve.

Liver.—The liver was pale yellow, with red patches of irregular outline beneath the capsule, which extended into the substance of the organ. On section there were numerous red patches resembling blood extravasations. Microscopically there were hæmorrhagic points which in places invaded and destroyed the lobules. The liver cells were much deformed, but still stained. The protoplasm was slightly granular. The condition of the liver was hæmorrhagic rather than degenerative.

Kidneys.—The kidneys were pale, and the capsule stripped easily, but they appeared normal to the naked eye. The only microscopical change of importance was cloudy swelling of the epithelium with granular protoplasm which stained badly.

Brain.—There was a large hæmorrhage in the right hemisphere, destroying a large part of the cerebral peduncle, and extending as far as the anterior wall and posterior limb of the internal capsule, skirting the corpus striatum. The third ventricle was much dilated, and there was a clot the size of a pea in the head of the caudate nucleus. The left ventricle was entirely filled with a large clot, part of the hæmorrhage extending forwards.

Another case of a like nature is recorded by Esch (18), under the title of "Eclampsia without fits." The following is an abstract of this case: On January 20th, 1899, Esch was called to a primigravida of 25, who had had pains since 11 p.m. on January 19th. Her last period was on April 14th, 1898. The history showed that she had passed bloody urine on the evening of the 19th, had had dimness and spots before the eyes, and had been twice sick. There was no abdominal pain, but severe headache; at 9 a.m on the 20th there was twitching of the face and complete blindness, but the patient was still conscious. When first seen the fundus uteri was between the navel and the sternum, the fœtal heart was audible, and there were slight pains; the os admitted one finger, and the membranes were unruptured. After the amblyopia great excitability came on, but with clear intelligence. At 12 noon the mental acuteness began rapidly to diminish, and this so quickly that by 12.30 the patient had completely lost consciousness. The urine was highly albuminous. The patient was removed to the Clinic; nothing happened during removal. On admission at 3 p.m. she was comatose, with deep stertorous breathing, and twitching of the face; the pulse was 84 and irregular, the temperature 39.7° C. The pupils were narrow and reactionless. The face was livid, and there was slight œdema of legs; cardiac dulness was not increased, the sounds were clear, and rhonchi were heard over the lungs. Uterine pains were present. The urine was drawn off by catheter at 7.30, and 150 c.c. of dark brown urine obtained; it was acid, sp. gr. 1018, and contained a few casts and leucocytes, but no red cells and no bile. The pulse-rate increased, and, without the occurrence of any fits, death took place at 11.20.

Post-mortem Report.—Unfortunately the *kidneys* were removed for demonstration purposes, and there is no record of their condition.

Liver.—There were irregular hæmorrhages under the serosa, from the size of a lentil to larger confluent plaques. The organ was clay-coloured on section, and showed many punctiform hæmorrhages. Its structure was ill-defined, and the boundaries of the lobules were not easily recognised.

Brain.—On removal of the skull cap there were punctiform hæmorrhages over the posterior part of the right parietal lobe; on section through the brain further scattered punctiform hæmorrhages were seen. In the posterior part of the right corpus striatum there was a hæmorrhage the size of a hazel-nut, which had destroyed the brain substance; the lateral ventricles, especially the right, were distended with blood-stained fluid.

No doubt other cases might have been found by a more exhaustive search, but our own case and the four others we have quoted are sufficient to support our contention that basal hæmorrhages form a definite complication of eclampsia, and are one of the causes of death in this disease. Further, these cases of "apoplexia gravis" ought to be recognised as a definite group of cases in which the eclamptic poison has chiefly affected the cerebral vessels. No doubt many such go unrecognised, for it is only where a post-mortem examination of the brain is made that their recognition is possible. For instance, one of us has recently seen an eclamptic case presenting many points of resemblance to these cases of death from basal hæmorrhage. A young primipara, a few days after labour, had headache and dimness of vision, with slight twitching, but no definite fit, and shortly became comatose. When seen she exhibited the deep coma and inactive pupils, the cyanosis and the tracheal rattling and stertorous respiration gradually becoming of the Cheyne-Stokes type—the very features which characterise the cases under discussion. The absence of a post-mortem examination makes it impossible to speak definitely of the nature of the case, but it strongly suggested the earlier one, on which this paper is based. This also applies to the case brought before the Glasgow Obstetrical Society by Dr. A. J. Wilson (19), under the title "Apoplexy (?) in a young II.-para." The patient, a woman, æt. 22, six months pregnant, went to bed in her usual health, but was observed early in the morning to be unconscious, having vomited dark-coloured fluid like blood; urine was passed involuntarily. There was no œdema or paralysis. The cervix was dilated, and the fœtus extracted. Next day there was some return of consciousness, and twitching of the hands and face were noticed. There was suppression of urine and incontinence of fæces. On the evening of the second day the coma deepened, and later paralysis of the left arm and leg was observed, accompanied by Cheyne-Stokes breathing. The urine had been passed involuntarily up to the time of death, which occurred on the fourth day. No post-mortem examination was permitted, and, unfortunately, also, there was no examination of the urine. These two cases are mentioned (even though the want of an autopsy renders them unavailable for the present purpose) merely to show that the occurrence of apoplexy in the course of eclampsia may be suspected when the case presents some unusual symptoms.

Indeed, in none of the cases under review was cerebral hæmorrhage recognised before death. It may be worth while, therefore, to note the most characteristic features of these cases. For the most part they occurred in young women (the ages being 24, 22, 38, 25, 25), and all in primigravidæ. This, however, but reflects the great preponderance of eclampsia cases among primiparæ, but the occurrence of cerebral hæmorrhage in women of this age points in a very striking way to the effect of the eclamptic toxins on the arterial walls. In our case pregnancy had only advanced as far as the fifth month; in another case to the eighth month; and in the other three to term; in two of the latter the symptoms began when the patient was in labour, and in one within a few hours of the termination of labour.

After some premonitory symptoms in the shape of headache, ocular disturbance, twitching or respiratory difficulty, the serious nature of the case was generally first shown by the onset of coma, which was sometimes, but not always, preceded by a fit. There was no fit in Meyer-Wirz's case or in Esch's; there was a slight fit in Pfannenstiel's, and possibly in our own, and in one only, Maygrier and Chavane's, were there repeated convulsions. Albuminuria was marked in all, and in three cases the urine is described as boiling solid.

The next point is the onset of deep coma, with little in the way of preceding convulsions, and without those occasional movements of the limbs and body which in the ordinary eclamptic comatose patient represent the occurrence of further convulsions. The effect of the damage to the grey matter and afferent and efferent tracts, and the increased intracranial pressure, is shown by the marked respiratory disturbance. The breathing is stertorous, with tracheal rattling, and in the later stages is of the Cheyne-Stokes type. Consequently, cyanosis is a very marked feature in all the cases; in illustration of this, attention may be drawn to the frequency with which oxygen was given and artificial respiration tried, and also to the way in which the patient's appearance at once suggested the advisability of bleeding. The pupils are described as inactive, equal in size, and of various degrees of dilatation. Probably the most striking picture would be provided by a case like our own, where the patient, after showing some of the premonitory symptoms of eclampsia, and with little or nothing in the way of convulsions, suddenly becomes deeply comatose, and has marked respiratory stertor and Cheyne-Stokes breathing.

The post-mortem findings, except for the large cerebral hæmorrhages, are the same as those usually seen in eclampsia. The kidney changes are described as cloudy swelling and granular degeneration of the renal epithelium, in some cases amounting to necrosis. The liver is described as hæmorrhagic and degenerate, and it is interesting to note that irregular red patches as noted in our case were seen also in Pfannenstiel's and in Maygrier and Chavane's case. This, however, we did not think had any part in the pathology of our case.

It will be noted that though in the majority of cases there was hæmorrhage into the pons, we have included any case where there was definite damage to the brain substance by hæmorrhage—in fact, we have excluded only the small meningeal hæmorrhages.

In bringing this case before the Section, and in commenting on it, we may hope that our error in diagnosis and our experience may be of assistance to the Fellows, and also that, by drawing attention to the occurrence of apoplexy in eclampsia, we may have helped to show that this is but another expression of the damage effected by the poison which is the cause of this disease.

THE TREATMENT OF LATERAL SCLEROSIS.

By WILLIAM MURRELL, M.D., F.R.C.P.,

Physician to, and Lecturer on, Medicine and Clinical Medicine at the Westminster Hospital, London; Examiner in the University of Aberdeen.

I am desirous of calling attention to a case which presents many points of interest. The man is 30 years of age, and was originally in the Royal Navy. Subsequently he specialised, and became a deep-sea diver. He is not suffering from caisson disease, and his occupation has nothing to do with the symptoms of which he now complains. He was admitted on April 8th, 1907, suffering from lateral, or spastic, spinal paralysis, the exact form being that technically known as Erb No. 2. I need hardly remind you that William Erb is Professor of Clinical Medicine at Heidelberg, and that he was a pupil of Nicolaus Frederick, whose name was conferred on a particular form of hereditary ataxy. Erb first described spastic spinal paralysis, or primary spastic paraplegia, in 1875. Only three symptoms were enumerated by him:—

1. A certain amount of feebleness of the lower extremities.
2. More or less muscular rigidity in the same region.
3. A marked increase of tendon reflexes.

No other symptoms were present, no anæsthesia or disturbance of sensation, no involvement of the bladder or of the functions of the organs of generation, no loss of nutrition of the structures of the muscles of the skin, and no anomaly of the brain, cerebral nerves or organs of special sense.

The three signs stood alone and by themselves. To this symptom-triad was subsequently added Babinski reflex.

Erb, on the basis of clinical and anatomical facts, and reasoning from analogy, arrived at the conclusion that the pathological condition underlying this syndrome, or collection of symptoms, was a chronic, slowly-ascending sclerosis of the lateral columns of the cord. Charcot a year or two later published a series of similar cases and arrived at a similar conclusion. Up to that time there was no post-mortem confirmation of the correctness of the pathological diagnosis. This came later, but not until after an interval of nine years, when Minkowski, in 1884, published a case in which there was the pure picture of spastic spinal paralysis with, as shown at the autopsy, sclerosis of the crossed pyramidal tracts. In rapid succession, Von Strümpell in Germany, Déjerine in Paris, and many other observers, published cases with autopsies, and the disease we now call "Erb No. 1." was placed on a firm pathological basis.

Erb, however, not content to rest on his laurels, in 1892 differentiated a second clinical form of disease, which, although presenting a strong resemblance to spastic spinal paralysis, differed from it in the fact that it was post- or para-syphilitic, and that there was always some disturbance of bladder function with a slight subjective and objective disturbance of sensation. This disease Erb described as "syphilitic spinal paralysis," and we usually speak of it as "Erb No. 2."

Our patient is suffering from this form of the disease. He gets tired on the slightest exertion, and his gait is distinctly spastic in character, as you observe when he attempts to walk the length of the ward. His reflexes are much exaggerated, and Babinski is distinctly in evidence. The difficulty in walking, he tells us, was first noticed about six months ago. Six weeks before admission there was dragging of both feet, with a constant tendency to catch the toes on the ground. About this time he noticed that the front part of the soles of his boots wore out much more quickly than the heels. You will observe that there is nothing indicative of involvement of the posterior columns, and that the pupils react both to light and accommodation. He says that for some months he has had incontinence of urine, with dribbling, especially at night. The urine, which has frequently been examined, is of sp. gr. 1012-16, acid, and contains neither sugar nor albumin. Sometimes, however, a little pus has been detected. There is no anæsthesia, and there has never been incontinence of fæces. With regard to a history of syphilis there is some doubt; at all events, there is no conclusive evidence. He has not always been a temperate man, and admits that for some years he took many glasses of brandy and water a day. In spite of the absence of any history of direct infection, there is very little doubt that the disease is of syphilitic origin, but whether it is a specific infiltration, an infection of the blood-vessels, or a degenerative change, it is difficult to say.

On admission, it was decided to give him the benefit of a course of antisyphilitic treatment. As a rule we give iodide of potassium in fairly large doses three times a day, and order calomel ointment to be rubbed into the abdomen night and morning. This answers well, but as it is not desirable to fall into routine methods, we decided in this case to give hypodermic injections of calomel. The dose selected was half a grain dissolved in vasinol, a 10 per cent. solution. This was injected with the usual antiseptic precautions deep into the muscles of the gluteal region in series of three spread over a week, and with weekly intervals. After the second week the patient was slightly salivated, but this was easily controlled. He had fifteen injections in all, and there was some improvement, especially with regard to spasticity.

From time to time we have used, in various forms of fibrous contraction thiosinamin, the allyl-sulpho-carbamide, prepared by warming oil of mustard with alcoholic solution of ammonia. The surgeons have made observations with it in Dupuytren's contraction, and have injected it hypodermically for removal of scar tissue with fairly satisfactory results. On the medical side it has been tried in cases of pyloric obstruction and in locomotor ataxy. It seemed to be indicated in our patient, for the sclerosis was probably the result of the deposit of fibrous tissue. Just as we were considering the matter our attention was called to a preparation known as tiodine, or thiosinamin-ethyl-iodide. It is an iodo compound, having a definite chemical composition, and is a combination of thiosinamin and iodine. The dose for hypodermic injection is 1 c.c., containing 3½ grains of the drug.

The first injection was given on June 25th, and was followed by a reaction. The febrile disturbance subsided on the fifth day by lysis. There was nothing pointing to pneumonia, pleuritic effusion, or ulcerative endocarditis.

In August the patient went home for a holiday, so that treatment had to be suspended. In October I gave the drug hypodermically to a man suffering from locomotor ataxy. It produced no reaction, and after six injections he left to return to work. The duration of the treatment was too short to give any definite result.

There are very few medical agents which have the property of raising the temperature. Thyroid will send it up to 101 or 102 degrees, especially in cases of myxœdema or cretinism. Strychnine may have some influence in this direction, but it is certainly not very marked. The only drug I know which really sends up the temperature is B.-tetrahydronaphthamine, and that is in rabbits and dogs. What may be its action on man I do not know. In rabbits the rectal temperature rapidly rises from 4.5 deg. to 5.5 deg. C. In these experiments the respiration was quickened, being about doubled in dogs and rabbits, and in cats reaching a rapidity of about ten times the usual rate. The heart beats much more forcibly, and the effect is purely cardiac and not vaso-motor. The drug is distinctly active, and doses of 0.01 to 0.05 exert a stimulant action on the heart, on respiration, and on metabolism.

On October 2nd our original patient returned to the Hospital, and he had not improved, in spite of the fact that his holiday had been spent in his native town, and under the most favourable hygienic conditions. His walking powers were very limited, and he was unable to stand without support. Babinski's sign was more pronounced, and ankle clonus was marked. The urinary trouble had increased, and there was such a degree of incontinence that the porringer had to be left in his bed. The urine had a sp. gr. 1015 and contained some albumin. He complained of spasmodic pains in the legs, for which he was give hypodermic injections, first of stovain and then of novocain, without benefit.

Finding that he was steadily getting worse, and that there was but little hope of improvement, I determined to continue the tiodine. After a few preliminary injections of stovain to eliminate the effects of suggestion, we gave two injections at intervals of three days of ten minims of tiodine. These gave rise to no elevation of temperature. On October 25th, at noon, the temperature then being normal, the patient was given fifteen minims subcutaneously. At 4 and 8 p.m. there was no rise in the temperature, but at midnight it was 100.2 deg., falling to 96.6 deg. at 4 a.m. At noon on the 28th the same quantity was administered, and at midnight the temperature was 100.2 deg., falling to 98 deg. at 8 a.m. On the 1st, 8th, and 10th of November the same dose was given, and was not followed by any rise of temperature. From November 14th until December 24th a dose of seventeen minims was given every alternate day.

The improvement in the condition of the patient was very marked, and this was especially noticeable with respect to locomotion. In October, on readmission, he was unable to stand without support, but by the middle of December he could walk with the aid of a stick. He could ascend a long flight of stairs to the convalescent room at the top of the hospital without assistance. In October he was disturbed twelve to fifteen times every night to pass water, but in December the nightly call was once or twice, and sometimes not at all. Another point which especially attracted his attention was that he could freely work the toes of his right foot, which before had been impossible. There is no alteration in the condition of his reflexes.

He has had twenty-six injections since October 25th. He has continued steadily to improve, and in a few days he is leaving us to take up active physical work on a poultry farm. The drug is undoubtedly useful, but its administration must be attended with caution.

DEDUCTIONS FROM ONE HUNDRED CONSECUTIVE OPERATIONS FOR APPENDICITIS.

BY J. W. DOWDEN, F.R.C.S.,
Surgeon, Edinburgh Royal Infirmary.

THE following remarks bear chiefly on acute appendicitis, and though illustrative cases are incidentally quoted, the author purposely abstained from entering upon details of operative procedure. Among the causes of appendicitis he could not but think that we must place an unhealthy condition of the mouth. He had been struck by the large proportion of cases suffering from sepsis of the buccal cavity, carious teeth, etc. Clinically he divided cases into two varieties—acute fulminant and mild. The symptoms were well known and usually distinctive: what were known as the "cardinal symptoms" scarcely required mention. In regard to the question of diagnosis, all cases of acute or subacute inflammation should be examined locally, as well as by the rectum. In some attacks of appendicitis, or when complications are present, any abdominal catastrophe may be simulated. He insisted strongly that no amount of skill or experience enabled one to diagnose the exact morbid condition of the appendix or the degree of complication in an acute attack; it was equally impossible to foretell what was going to occur; the symptoms only pointed to what had actually taken place, not to future complications. As regards the sex in his series, 66 were males, 34 females. The acute cases showed 52 males and 30 females, with a mortality of 16; the interval cases, that is, those who had survived an acute attack, gave 14 males and 4 females, with no deaths. Second attacks had occurred in 37 of all his patients. Of the 82 acute cases, the age distribution was as follows: Under 16, 16, with 6 deaths; 16 to 30, 50 cases, with 9 deaths; over 30, 16, with 1 death. Of these, 19 had had previous attacks, and 3 died. Suppuration was present in 58, and 14 died. Coming to the date of operation, in relation to the death rate, his figures were as follows: Operation on first day, 11, with no deaths; on second day, 16, with 2 deaths; on third day, 18, with 7 deaths; on fourth day, 10, with 1 death; on fifth day, 5, with 2 deaths; on sixth day, 1, with 1 death; on seventh day, 7, with 2 deaths; after seven days, 14, with 1 death. He regarded the prognosis in acute appendicitis always serious, because it was absolutely impossible to foretell what course the disease would take. It was essentially a surgical affection, and the logical treatment was removal of the appendix as early as possible. This was really the chief deduction made—that as soon as appendicitis was diagnosed the appendix should immediately be removed.

THE WOMAN OF THE FUTURE, FROM A GYNÆCOLOGIST'S POINT OF VIEW (*a*).

BY ED. OCTAVIUS CROFT, M.D.,
President of the North of England Obstetrical and Gynæcological Society; Senor Surgeon to the Leeds Hospital for Women and Children.

AT the commencement of his address the author referred to the frequency with which members of the profession looked back at the work of their predecessors, and in doing so were apt to congratulate themselves on the brilliant achievements of the present day, without considering whether the progress of our knowledge was having a clear run, and whether it was being diverted into side issues or hindered by developments which might be of immense immediate value, but which might obscure the main issue. He suggested picturing in mind a typical healthy woman in the more or less distant future, and estimating the probability of her enjoying an immunity from many of the physical and mental disaffections as known to the present-day gynæcologist. She would require the command of a much higher knowledge of prophylaxis and of the conditions of normal health, and such knowledge would have to become an integral part of her own mental equipment and the laws of health to be obeyed in an almost automatic manner. The indications of such a development were referred to and exemplified. Rapid advances were liable to be associated with the development of exuberances of rapid growth and feeble vitality. These exuberances were temporary hindrance, and were more liable to form in the process of mental than physical development. They chiefly appeared in the form of eccentricities of various kinds. The general advance of bodily soundness in women was thought to be checked rather than aided by the exuberance of many quack proceedings in connection with physical culture which existed to-day.

The various classes of gynæcological disease were reviewed in the light of their ultimate avoidance. The large class of inflammatory affections which were mainly associated with microbial infection of varying degrees were to be looked upon as avoidable, as also were manv of the disorders of pregnancy and abnormalities of labour. The eradication of venereal infectious diseases was not being dealt with at all at the present day; it was to be hoped that a more common-sense view would be taken of this matter in a more enlightened future. The prevention of puerperal infection seemed a difficult lesson to learn, in spite of its simplicity. It was suggested that the ultimate solution of the question would be in the hands of the suffering womenkind. When they themselves fully realised the position they would demand the remedy, and the demand would be more quickly met.

With regard to the possibility of dealing with the apparently hopeless conditions of maldevelopment, the suggestion of Dr. Balantyne and the subject of eugenesis were referred to. There is no clue, he contended, to the prophylaxis of the new growths of the female organs, such as cystic disease, fibroids, and cancer. Referring to fibroids, the brilliant results of a curative kind obtained by operation during recent years, while of enormous immediate value, has practically paralysed all research into the ætiology and nature of these growths. More work is being done regarding cancer, but the high degree of technical skill required of the operator and the pathologist has rather tended to create a chasm between the two which is difficult to bridge. Both are liable to be lacking in the opportunity for the observation of the living habits and phenomena of the disease as it progresses in the patient. It would be interesting to revisit the earth at some future time to ascertain the extent to which the future woman had succeeded in avoiding the ills to which she is now liable.

(*a*) Abstract of Presidential Address delivered before the North of England Obstetrical and Gynæcological Society, January 17, 1908.

THE REV. C. H. YATMAN, of New York, who is staying at the Langham Hotel, has come to London as the representative of Mr. Nathan Straus, of New York, to look over the ground with a view to extending Mr. Straus' pasterised milk campaign to London. Mr. Straus has been giving away and selling at cost, in New York, millions of bottles of pasteurised milk for feeding infants, and the great reduction in infantile mortality in that city is attributed by the public health authorities almost solely to his efforts.

OPERATING THEATRES.

ST. THOMAS'S HOSPITAL.

CASE OF ENLARGED GALL-BLADDER.—**MR. H. BETHAM ROBINSON** operated on a man, æt. 59, who had been admitted with the following history:—For eight months there had been tenderness in the right hypochondriac region, and there was also some pain on bending. He had had lumbago at times, but he was a rheumatic subject. He had no digestive troubles, but had more or less constipation. He had no special symptoms referable to the liver, and no loss of weight. On examination, the abdomen was normal, except for a very definite oval lump of a sausage shape extending down from the right costal margin under the right rectus as low as one inch below the umbilicus; its lower edge was distinctly rounded; it moved downwards on inspiration; there was some impaired resonance over it which merged into the normal liver dulness. Nothing else abnormal was to be found on general examination; the temperature and urine were normal. It was obvious, Mr. Robinson said, from the examination that the case was one of distended gall-bladder, and the absence of any jaundice, white stools, dark urine, or enlarged liver made him confident that the obstruction to the gall-bladder was in the region of the cystic duct. At the operation the liver cushion was used. A vertical incision was made in the line of the outer third of the rectus, splitting the muscle. A very distended gall-bladder was brought out of the wound adherent to a thinned-out portion of a small liver; the gall-bladder had a pale, translucent appearance, and its body was about six inches long and two inches in diameter. After packing off the abdomen with gauze, the fundus of the gall-bladder was tapped and a clear fluid, like dilute glycerine, drawn off. An incision was now made into the gall-bladder, and nine stones, facetted, were removed. On examining the neck of the gall-bladder, another hard mass was felt lodged in the beginning of the duct; this lump could not be displaced backwards in the gall-bladder, so an incision was made down on it through the walls of the duct, and two stones, facetted like the previous ones, were removed. A probe passed through this opening down the cystic duct and down the common duct gave no evidence of there being other stones present. The wound in the duct was stitched up with interrupted fine silk sutures, the mucous coat being avoided. A rubber drain was fixed in the fundus of the gall-bladder, the rest of the incision being stitched up with some fine silk. The fundus of the gall-bladder at the sides of the rubber drain was fixed to the peritoneum and posterior sheath of the rectus. A "cigarette" drain was passed down to the region of the neck of the gall-bladder, coming out of the abdominal wall just below the attached fundus. The abdominal wound was then closed in layers. Mr. Robinson remarked that the operation had confirmed the diagnosis of distension of the gall-bladder from obstruction about the cystic duct, this obstruction proving to be impacted calculi, causing gradual backward distension of the gall-bladder by its own mucous secretion. The condition of the gall-bladder was that designated hydrops or mucocele. He pointed out that impacted calculi or new growth were the most likely causes of the enlargement, but the absence of any marked wasting and cachexia or general symptoms seemed to put the idea of malignant disease out of court. As for the treatment adopted it was seen, he said, that the gall-bladder was drained and afterwards fixed to the abdominal wall; it might be urged that after removing the obstruction and suturing up the wounds in the neck of the gall-bladder and its fundus the viscus could have been dropped back into the abdomen; this, however, was a risky procedure as subsequent distension of the gall-bladder might be followed by extravasation. On the other hand draining the gall-bladder was perfectly safe and had distinct advantages; leakage was unlikely to occur from want of tension, the character of the fluid entering the gall-bladder is satisfactorily determined, and the drainage itself lessens or prevents any subsequent infection of the walls of the gall-bladder. It might be urged by some, he suggested, that this was just the case in which a cholecystectomy might have been done at this time. The propriety of doing this, however, depends very much on the surgeon's individual opinion, and there were advantages in determining what is the condition of affairs after the removal of the obstruction, in other words it is a perfectly safe procedure even if there should be an overlooked stone in the common duct low down, whereas if such should be the case considerable risk may be run after removing the gall-bladder.

The next day the "cigarette" drain was removed, and bile was coming from the gall-bladder, showing the restored patency of the cystic duct. There was a slight rise of temperature to 101.2 on the second night after the operation, but this disappeared in the morning, and was the only occasion on which the temperature was above normal. The stitches from the abdominal wound were removed on the seventh day; the tube in the gall-bladder came out on the tenth day, and was not replaced; the escaping bile from the fistula rapidly lessened, and all drainage had ceased by the fourteenth day.

The fluid from the gall-bladder at the operation proved to be bacteriologically sterile, and no cells were seen. The facetted stones were highly polished, of lightish brown colour, and in the main were composed of cholesterine.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD FRIDAY, JANUARY 17TH, 1908.

MR. SETON PRINGLE in the Chair.

GRAFTING OF FIBULA TO TIBIA.

MR. R. ATKINSON STONEY read the notes of a case in which he had grafted the fibula to the tibia. Patient, a boy, æt. 7, was admitted to the Royal City of Dublin Hospital, November 26th, 1905, suffering from acute osteomyelitis of tibia; he had been ill for ten days, and a huge abscess had formed involving the whole of leg from knee to ankle. The abscess was opened immediately, and the diaphysis of the tibia was found completely stripped of its periosteum. The necrosed tibia was removed by two operations, in January and April. By April, 1906, the sinuses had closed, and an involucrum had formed in the lower and upper parts of the leg, but there was a gap of about one and a half inches between the two ends, due to destruction of the periosteum, as the result of the virulence of the original infection. An operation was performed in which the neck of the fibula was cut across and the upper end of the lower fragment implanted into the upper end of the involucrum of the tibia. Firm union has now occurred, and the boy is able to run about without the aid of a stick, though there is considerable shortening, as the result of over a year's loss of growth while the illness lasted, and the ends of the tibia were not in contact. The operation is a modification of one described by Hahn in 1885, and was suggested by a case reported by Professor E. E. Goldmann, of Freiburg, in the *Lancet* of January 13th, 1906.

The **CHAIRMAN** said the case was, so far as he knew, the first of the kind reported in Ireland, or at any rate shown at the Academy. He believed it was the only line of treatment which was likely in such a case to leave a useful limb.

Mr. **Taylor** congratulated Mr. Stoney on the success of his operative procedure.

Dr. **Stokes** asked if there was any tendency of the ankle to turn outwards.

Mr. **Stoney**, in reply, said there was no tendency of the ankle to turn outwards. If anything, there might be a tendency to turn inwards, but such was hardly likely in the present case.

POST-ANÆSTHETIC VOMITING.

Dr. **Gunn** read a paper on the above subject. He first drew attention to the fact that, as the anæsthetists had not the after-treatment of operative cases, they only to a slight extent realised what a troublesome complaint post-operative vomiting might be. He believed it was the duty of the surgeons to use every means in their power to prevent this vomiting. Dr. Gunn himself had been using a method, suggested by MacArthur, of giving the patient frequent drinks of pure cold water right up to the administration of the anæsthetic, and this method had been entirely successful in nine cases, partially successful in 19 cases, and had had no result in 12 cases, out of the 40 patients who had been treated in this way.

The **Chairman** said he had, some years ago, carried out a series of observations on the action of the kidneys during anæsthesia. He found that the amount of nitrogenous material and water excreted during the anæsthesia was very small; but as soon as the patient came out of the anæsthetic the kidneys began to act, and there was a hyper-excretion of water and an increased excretion of nitrogenous material for some hours. It was possible that in this lay the explanation of the pain across the loin. He had noticed when administering anæsthetics that the less the patient was cyanosed during the administration the less vomiting there was afterwards, so that it was important to let the patient breathe a certain amount of fresh air.

Dr. **Kirkpatrick** said anæsthetists had not seen enough of their patient, either before or after the administration, to have had the importance of the question of post-anæsthetic vomiting impressed upon them. For some years he had considered the question, and disagreed with Mr. Gunn on some points. He (Dr. Kirkpatrick) thought the preparation of a patient had a good deal to say to the condition of the patient afterwards, provided the preparation was satisfactory. He did not look on abstinence from food as of such importance as thorough purgation some time before the anæsthetic was administered. Various writers pointed out that the patients who usually gave most trouble with post-operative vomiting were those who suffered from more or less chronic constipation. He did not agree that the nature of the drug used had no very great effect on the post-operative condition. Occasionally after chloroform anæsthesia vomiting became so serious as sometimes to threaten the patient's life; such was exceedingly rare after ether. He was inclined to believe that the *method* of administering the anæsthetic—the nature of the anæsthesia obtained—was of far more importance than any other factor. The Chairman had pointed out the importance of avoiding cyanosis, and of giving fresh air; when patients were treated by that method they soon recovered, and vomiting was exceedingly uncommon. He would add that anæsthetists had been in the habit of maintaining a depth of anæsthesia which was quite unnecessary in most operations. He had carried out experiments, as the Chairman had, which showed a great diminution in the function of the kidneys, and he could not but think that in a patient who was profoundly anæsthetised there must result a very profound toxæmia. The activity of the renal epithelium in certain animals was not at all as much diminished as it was in the human being during anæsthesia, and it was very probable that that inactivity was associated with a fall in blood pressure.

Mr. W. I. **de Courcy Wheeler** said he had tried the open method of administering ether, and had found it very simple and the anæsthesia perfect. The patients never became cyanosed, but he had not had enough experience of the method to say whether the vomiting was less frequent. It was particularly suitable for old or fragile persons. Alcoholics, who were difficult to get under ether, vomited less than other patients; if the anæsthesia was begun with choloroform and continued with ether, the vomiting was far worse. Local anæsthesia was, he thought, the ideal method. It was perfectly safe to give if the proper drug was used.

Dr. **Pugin Meldon** said he found it useful to keep patients under the anæsthetic until they were back in bed. In that way the vomiting was not started; they went off into a sleep, and got rid of a good deal of the anæsthetic.

Sir **Thomas Myles** thought that very little was known as to the cause of post-anæsthetic vomiting. He had known a lady, prior to the introduction of aseptic technique, to vomit incessantly for twelve days. Every drug, except one, that they could think of, was administered; finally she was given half a grain of morphia hypodermically, and the vomiting ceased. He himself had been under every anæsthetic known. He had always insisted on having a cup of tea before the operation, and he was well purged out. He had never vomited or had a fit of sickness. He was inclined to think that the sickness was due to something inherent in the patient. In the majority of cases he thought they would be found to have some kidney trouble. He thought the experience from which Mr. Gunn made his deductions was too limited. If a careful analysis of the 20,000 cases administered annually in Dublin were made, as regards the urine and the vomiting, then they might be justified in making deductions; but merely to say that in 20 per cent. of cases albumen was present was not sufficient evidence on which to base a generalisation. If a patient was kept on a table in a cold room they could not help giving them a renal chill.

Mr. **Taylor** felt that cyanosis had something to do with the vomiting. In most cases of abdominal sections which he had done it had been his habit to give morphia either immediately before the anæsthetic or before leaving the table; less anæsthetic was then required, and there was less vomiting. He thought the vomiting was less the result of swallowing the anæsthetic than of nervousness.

EXOPHTHALMIC GOITRE.

Sir **Thomas Myles** read a short paper on a case of exophthalmic goître which he believes to have been cured by a diet of milk obtained from a thyroidectomised goat. The patient was a married lady, 25 years old, and the symptoms had been developing for more than a year. All the well-marked features of the disease were present, and there had been a progressive loss of strength and colour. The goats were operated on by Professor Mettam, of the Veterinary College, whose co-operation was gratefully acknowledged by the speaker, and when, two days later, the little wound in the neck had healed, the goats were sent to the patient, who resided in the country, and the treatment was begun and steadily persisted in. At the end of a month the improvement was very marked, and at the present moment the enlargement of the thyroid is barely perceptible and the exophthalmos has disappeared. For the last few months the milk diet has been supplemented by the use of Merck's tabloids, and in the administration of small doses of iron and arsenic. Sir T. Myles in bringing the case under the notice of the section did so with the hope of inducing other practitioners to give the method, which is simple but not costly, a fair trial.

Mr. **Taylor** said the method had been tried on the Continent some years ago, and a powder made from the milk of thyroidectomised goats could be bought, but the professors on the Continent had not spoken much in its favour.

Mr. W. I. **de Courcy Wheeler** said the main danger was that, even if the symptoms apparently abated, the patient might at any time drop dead. He had seen astonishingly good results of operative treatment abroad, but he thought the operation must be an extremely difficult and anxious one to perform.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD WEDNESDAY, JANUARY 15TH.

The President, Dr. JAMES RITCHIE, in the Chair.

MR. F. M. CAIRD showed a specimen of carcinoma of the stomach removed by Billroth's second method.

Dr. R. A. **FLEMING** showed a man suffering from defect of articulation, spastic diplegia, and marked intention tremor, all dating from infancy. As regards the nature of the lesion, he had no doubt that it was cortical. There was no history of birth injury, nor any mental defect; the diagnosis lay between a meningeal hæmorrhage and a meningo-encephalitis. There was no family history of any similar disease. The father of the patient had a stammer resembling that of the case in question.

Mr. J. W. **DOWDEN** showed a patient after operation for perforated gastric ulcer. The perforation had been found close to the duodenum, on the lesser curvature, and he had removed the whole ulcer by a lozenge-shaped incision in parallel with the long axis of the lumen of the stomach and intestine. The duodenal sphincter had been cut into by the incision, and subsequently a pyloroplasty had been performed so as to obviate the possibility of any stricture. He had performed a similar pyloroplasty in perforated gastric ulcer in this situation on three other cases, with favourable results.

Mr. F. M. **CAIRD** showed a patient who had been operated on for cancer of the tongue. There was no glandular involvement. The operation had been done under local anæsthesia, cocaine being used. The right half of the tongue was excised. It was noticeable that a few hours after the operation there was very little interference with articulation. Healing was very rapid, as was usual in cases of excision of the tongue under local anæsthesia. Ten days later, as a precautionary measure, all the glands on the right side of the neck were dissected out. Subsequent microscopic examination had failed to reveal any carcinoma. The operation had been performed several years ago, and now the patient had returned because of a lump under the jaw. This was, Mr. Caird thought, almost certainly a cirrhotic condition of the submaxillary gland, and not malignant. He had observed such a state of matters in several previous cases. The gland could not, however, be distinguished from a malignant growth by the touch; the fact that the size of the tumour varied was in favour of the theory of cirrhosis. He proposed to remove the gland. (2) A patient with recurrence four years after enterectomy for malignant stricture of the colon. At the original operation, the patient at the time suffering from acute obstruction, a simple artificial anus had been made. A few days later the tumour was removed. There had been no recurrence until quite lately, when the patient had become jaundiced and lost weight. Tumours could now be felt near the original wound and in the region of the liver. The point which the case illustrated was that when a malignant tumour of the alimentary tract was thoroughly removed, local recurrence was less to be feared than a diffusion of the cancer by way of the lymphatics.

Dr. EDWIN **BRAMWELL** showed a boy who, after an acute onset, with some vomiting, had inability to move the head. On further examination the following symptoms were found. The movement of the head in all directions was feeble. The sterno-mastoids were weak, and gave slight reaction of degeneration. The right side of the tongue was atrophied, and the right pupil was contracted, and the right palpebral fissure narrower than the left. At first the case was thought possibly to be one of caries of the cervical vertebræ, but this had now been discounted, as the X-ray examination and Calmette's reaction were negative. The lesion appeared to be restricted to the sympathetic, and the nuclei of the spinal accessory and right hypoglossal. The diagnosis was polio-encephalo-myelitis.

Mr. ALEXIS **THOMSON** showed (1) a case after osteoplastic amputation through the middle of the leg, in which a portion of the tibia was retained in the anterior flap and brought into contact with the sawn section. Though the amputation was a recent one, the stump was so firm that it could be used as a bearing point for an artificial limb. (2) A boy of 17, with deformity of the lower limbs, consisting of contracture at the knee, and crossing of the legs, from spastic paralysis, following Pott's disease, in whom an attempt had been made to restore the weight-bearing capacity of the limb by osteotomy of the femur and transplantation of the tendons of the semi-membranosus and biceps into the patella. As a result the limb was now straight. It was proposed to perform arthrodesis of the ankle, and subsequently to treat the other leg in the same fashion.

Dr. CHALMERS **WATSON** showed two cases of chronic pancreatitis, one illustrating the form associated with, the other without, calculus in the pancreatic duct. It was a feature of the calculus cases that recurrent ague-like attacks took place at more or less regular intervals. Both patients gave Cammidge's pancreatic reaction, which Dr. Watson also demonstrated. It depends on the presence in the urine of a substance which on hydrolysis yields a pentose, and can be detected by the phenyl-hydrazin test. The different stages of the reaction were illustrated, and photographs showing the characteristic ozazone crystals, as compared with those of phenyl-glucosazone, were thrown on the screen.

Mr. W. J. **STUART** demonstrated the pneumatic sigmoidoscope, which had these advantages over the ordinary instrument:—It is not necessary to place the patient in the knee-elbow position; the speculum is introduced by the aid of sight, hence there is no risk of damaging an ulcer, etc., as when touch alone is relied on for a guide; the interior is always properly illuminated, and appearances can readily be demonstrated to students. The sigmoidoscope consists of a tube graduated in centimetres. It is provided with an obturator for use in passing through the external and internal sphincters, but which is then removed. A small electric lamp is then inserted and thereafter an air-tight window is screwed on. Then, by means of a small bellows, the air is pumped into the sigmoidscope, so as to distend the bowel in front of it, and as this is done it is gently pushed further in. The air prevents its edge from coming into contact with, and damaging the wall of, the gut. When an ulcer or tumour is detected, it can be allowed to fall against the orifice of the sigmoidoscope by letting the air escape; it is then an easy matter to remove a portion for examination by the aid of a special pair of forceps.

Mr. J. W. **DOWDEN** read a paper entitled

DEDUCTIONS FROM 100 CONSECUTIVE OPERATIONS FOR APPENDICITIS,

which will be found in abstract on page 122.

The paper gave rise to a full discussion centreing entirely round the question of when cases should be operated upon.

Mr. **COTTERILL** said he supposed that everyone was agreed that when one attack of appendicitis had occurred the appendix ought to be removed. The "interval cases," therefore, called for no special remark. The crux of the whole question hung round the acute cases. He did not quite agree that one could never foretell what was going to happen; he thought that careful, frequent observation settled one main point—namely, whether the patient was improving or getting worse. It was perfectly true that if one operated, say, within 24 hours, the risk was small. It was very much greater, however, from the second or third up to the tenth day. His experience, therefore, was that, provided the symptoms were subsiding, it was better to postpone operation until the acute attack had subsided. He made the reservation, however, that if the case was in the country, and not within easy reach, it ought to be operated on at once, to avoid the risks of delay.

Mr. **MCGILLIVRAY** agreed generally with Mr. Cotterill's opinion, and thought that it was advisable to postpone operation until the acute stage was over, provided that the patient's symptoms were abating. With regard to the propriety of insisting on the removal of the appendix after a single attack of appendicitis, he was not prepared to go so far as the previous speakers. In cases where, after a mild attack, all the symptoms subsided, and in a fortnight or three weeks there was not the slightest trace of pain or tenderness about the abdomen, he had never felt justified in urging the patient very strongly that he must undergo an operation.

Dr. **Affleck**, speaking from the physician's standpoint, strongly dissented from the opinion that, once an attack of appendicitis had occurred, the appendix never became normal again. He was convinced that in many cases Nature worked a cure. He was in no way against operation, and had derived great help in treating the disease from his surgical colleagues, but he was strongly opposed to laying down any such hard and fast rule as that every case of appendicitis required immediate treatment by operation. In this connection he alluded to the difficulties which often arose in diagnosis. Sometimes it was extremely hard to say whether or not a patient was actually suffering from appendicitis. His position was that, without unduly deprecating surgical intervention, it was most important to individualise, and to judge every case on its own merits.

Mr. **Caird** said that the first point he might allude to was the fact that most of the surgeons present could bring forward long series of operations for appendicitis; yet it did not seem so very many years since he had shown what was, he believed, the first appendix demonstrated to the Society as having been removed by operation. He wished to discuss the question of the mortality in the two sets of cases—acute and interval cases. He had recently been looking over his results, and found that his last 170 interval cases had included no deaths. Looking at statistics over all, the mortality in this class of case worked out at a fraction of 1 per cent., and probably that death-rate was unavoidable. They had to remember that in these cases they were operating on an already infected region, and that every now and then, despite all these cases, bad results would be got. He instanced a case of interval operation to illustrate this point. The patient three years before had had an acute attack of appendicitis treated in the country by the incision and drainage of a large abscess. A ventral hernia had ensued, and Mr. Caird had had to operate for the relief of this. At the operation the appendix was found quite free from adhesion, and lying free in the peritoneal cavity. The only sign of old disease was a little exudate lying on its peritoneal aspect near the root. This was carefully removed, and on inoculation into culture tubes gave a growth of b. coli and cocci. Now here we had, as the result of old appendicitis, an infective focus lying inside the peritoneal cavity. He could only suppose that the reason it did no harm was because the peritoneum had such resisting power, but that such a state of matters existed showed that every now and then the interval operation was likely to be attended with serious results. Turning to his operations in acute cases, ever since Beesly's paper on "Delayed Chloroform Poisoning" had appeared, he had habitually substituted ether as the anæsthetic; he was bound to say that his mortality was just the same as before. He could look back, however, on two or three early cases in which he believed now that death had been due to delayed chlorform poisoning. Mr. Stiles was less pessimistic than Mr. Dowden as to the possibility of forecasting the course of a case of acute appendicitis. He thought one could always recognise the fulminant type, and if this were seen within 48 hours he always advised operation at once. Indeed, he thought that when one saw such a case at night it should never be postponed until next day, but sent off to a nursing home and operated on straightway. The difficulty, of course, was in patients seen after the second day. Here he thought each man's individual experience must be the best guide. If the surgeon was in doubt he ought to operate. It should also be remembered that if one delayed operation in an acute case it might be six or eight weeks before the patient was fit for the interval operation, and then the removal of the appendix added several weeks to his convalescence. On the other hand, early operation meant that the patient was well in two or three weeks. He thought that as time went on the mortality of operations during the acute stage would fall. When appendicectomy was first practised, surgeons, on the whole, were surprised if patients recovered; now they were surprised if patients died. He thought the diminished mortality he now had was due to four things:—(1) To the fact that he had given up disturbing peritoneal adhesions, and did not attempt thoroughly to cleanse the peritoneum; (2) to using free drainage; (3) to sitting the patient up after operation so as to favour drainage into the pouch of Douglas; and (4) to the use of rectal salines, which he thought were better than intravenous injections. He also believed that the substitution of ether for chloroform in operations on all infective abdominal conditions had lowered the mortality, particularly in children. Another point he wished to refer to was the presence of fine crepitation due to minute bubbles of gas under the skin in cases of deep-seated abscess. This had sometimes helped him to recognise a deeply-seated retro-cæcal abscess.

Dr. **McAllum**, speaking as an anæsthetist, urged that surgeons should give ether a fair trial in septic abdominal operations. He was convinced that by doing so they would lessen the number of cases of post-anæsthetic acetonuria.

Dr. W. T. **Ritchie** said that he had seen several cases said to be of delayed chloroform poisoning which had proved to be septicæmia.

Dr. **Gulland** thought it was out of the question to assert that every patient with appendicitis should be operated on. Every physician knew great numbers of people who had had an attack of appendicitis, recovered completely, and were never thereafter troubled again.

Dr. **James Ritchie** spoke of appendicitis in relation to life assurance, saying that whereas he would load a life if an attack of appendicitis had occurred, he would pass it as first-class if the appendix had been removed. In practice, he said, it was impossible to insist on the removal of the appendix of every patient who had had an attack. If it was mild, and if recovery was complete, he shrank from putting the patient to the risk and expense of an operation. If, however, a second attack developed, then the appendix should at once be removed.

Mr. **Dowden** replied to the discussion.

Dr. R. A. **Fleming** gave a lantern demonstration of the

CHANGES IN THE OPTIC NERVE IN A SERIES OF CASES OF INTRA-CRANIAL TUMOUR.

He first showed the neuroglia in the normal optic nerve, and then the hypertrophied neuroglial cells in disease. In optic neuritis the change consisted in an hypertrophy of the neuroglia, and this hypertrophy was much greater in the neuritis consequent upon intra-cranial tumour than on that due to simple local irritation. In cases of brain tumour there was a similar hypertrophy of the neuroglial cells of the brain substance. Similar changes were found in albuminuric optic neuritis. Only the neuroglial cells, not the mesoglial, were affected. The exact pathogenesis of optic neuritis in intra-cranial tumour was not known. Of the two hypotheses as to its cause—increased intra-cranial pressure and a toxic action—the latter was probably correct.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Meeting held January 17th, 1908.

Dr. A. J. **Wallace** (Liverpool) was elected President for 1908, and office-bearers for the ensuing year were elected.

Dr. E. **Octavius Croft**, the retiring President, delivered a valedictory address on

THE WOMAN OF THE FUTURE, FROM A GYNÆCOLOGIST'S POINT OF VIEW,

a full abstract of which will be found on page 122.

Professor Chantemesse, of the French Academy of Medicine, has announced the possibility of a cholera epidemic along the Mediterranean seaboard next spring. If the cholera got to the Mediterranean ports the outlook would be grave, and it has broken out at Mecca already.

CORRESPONDENCE

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Jan. 26th, 1908.

Ophthalmo-Diagnosis of Consumption.

Dr. Calmette read a paper last week at the meeting of the Académie de Médecine on the ophthalmo-diagnosis of tuberculosis.

Since I made known, he said, by a communication to the Académie des Sciences last June, the first results of what I termed the ophthalmo-diagnosis of tuberculosis, a large number of doctors were able, by repeating the experiment, to affirm that this method permitted to diagnose, with almost absolute exactitude, the existence of tuberculous lesions in process of development in the absence of any apparent clinical sign.

It is only right to state that before me Wolff-Eisner had announced to the Medical Society of Berlin that tuberculous subjects presented a charcteristic reaction when a drop of a solution of the old tuberculin of Koch and glycerine (1—10) was introduced into the eye. However, I had no knowledge of this communication.

After my first experiment, I found that this glycerine solution irritated considerably the conjunctiva, and consequently abandoned it, preferring a formula of my own. I precipitated the tuberculin three times in proof spirit, removing thus all impurities, when it was re-dissolved in physiological salt water at the dose of one per cent. One drop of this solution introduced into the internal angle of the eye is sufficient to produce, if the patient is tuberculous, a characteristic reaction. In children it should be of half the strength (1—200) on account of their sensitiveness being naturally more exaggerated.

Already hundreds of thousands of patients of all ages have been submitted to this test, both in France and abroad, and it seems now firmly established that ophthalmo-diagnosis, employed with the precautions suggested, furnishes indications as exact as those given by subcutaneous injections of tuberculin, presenting, on the other hand, an advantage over the latter in the fact of it being inoffensive.

Although this test has been employed more or less inconsiderably, and proper precautions have not always been taken to avoid, by antiseptic lotions, the introduction of infectious germs into the eye during the reaction, very few cases of persistent conjunctivitis or of keratitis have been observed. These complications are not in reality due to the tuberculin, but to pre-existing or imported infectious germs (bacilli of Weeks, staphylococci, gonococci). In many cases such accidents could have been avoided if, instead of using the solution which is rapidly spoiled by exposure to the air, tubes of sterilized tuberculin were used. According to M. de Lapessonne, the ophthalmo-reaction presents no danger to the healthy eye, and with the usual precaution of cleanliness, its employment is inoffensive, except, perhaps, in aged persons.

The interpretation of the results of ophthalmo-diagnosis is certainly sometimes a very delicate point. First, the reaction takes place with very variable intensity. Sometimes it shows itself four or five hours after instillation, and disappears at the end of 12 or 16 hours. The conjunctiva is only slightly injected, especially in the neighbourhood of the caruncculus, accompanied by lacrymal secretion. At others the vascular redness becomes perceptible only after 24 or even 48 hours, and persists five or six days. The patients complain of no pain, only of a smarting sensation in the eye, and some trouble of the vision provoked by the abundance of the secretion. Chemosis is never observed, nor is the temperature affected; the reaction is purely local.

It is good practice to examine the patient at three successive periods—6 or 8 hours, 24 and 48 hours after instillation of the tuberculin. If the test was made on the left eye, for instance, the colour of the caruncculus should be compared with that of the right eye. If the reaction has commenced, and although there may be no redness of the conjunctiva nor lacrymal secretion, the caruncculus of the tested eye will be seen to present a dark red colour which is characteristic. When the reaction is negative, the colour of both caruncculi remains the same.

The intensity of the reaction does not appear to be in direct ratio to the extent or gravity of the tuberculous injection. However, it is more intense and more rapid in children and adults who present incipient lesions barely discernible clinically.

In pronounced tuberculous patients, the reaction is slow to appear, and is less marked. In cachectic persons and those suffering from tuberculous peritonitis, no reaction takes place, but here also the subcutaneous injection of tuberculin is negative.

As regards infants born of tuberculous mothers, the ophthalmo-diagnosis does not react in the first months of their existence. On the other hand, children of one or two years react in the proportion of 3.5 per cent., and this proportion increases rapidly with the age, so that at between 10 and 19 years it attains 15 per cent.

These facts would seem to confirm the idea now in vogue that the child is not born tuberculous except in very exceptional cases; they become tuberculous from contagion or from being fed with milk from tuberculous cows.

In any case, the ophthalmo-diagnosis applied to each member of a family when tuberculosis is suspected, warns the physician of the impending danger before any clinical signs are apparent, and as the malady, treated at its very outset, is generally curable, the attendant is armed for the struggle with the maximum of chances towards success.

The utility of the ophthalmo-diagnosis can extend over a much larger field. It could be used for eliminating candidates for the Army, Navy, public schools, etc., who from a previous medical examination are more or less suspected of tuberculosis.

GERMANY.

Berlin, Jan. 26th, 1908.

At the Medizinische Gesellschaft, Hr. L Hirsch showed a young child that had been brought to him a year before with

Tuberculosis of the Supra-orbital Margin.

He then thought that success could be obtained with conservative treatment, and recommended this, and then lost sight of the child. When it was brought to him again, however, he found that it had suffered a great deal from pain, and that the eye was completely mummified. If he had carried out a radical course of treatment a year before, a great deal of pain at least would have been saved.

A second patient shown was a man of 42, who, after two day's headache and giddiness, became afflicted with complete amaurosis, bilateral pupillary rigidity, and paralysis of the abducens. Although the man denied syphilis, he was at once put upon an energetic course of inunction treatment. The result followed. His sight recovered so far that, in spite of bilateral atrophy of the terminals of the optic nerves, the vision on left was V = 6/20, on the right V = 6/12.

Hr. O. Pielicke then spoke on

Tuberculin in Tuberculosis of the Kidney.

The speaker recognised the brilliant achievements of surgery in renal tuberculosis, but he claimed that treatment by tuberculin could also do good service. As an example of this he related the case of a woman, æt. 42, whose right kidney was distinctly tuberculous, and in whom a cystoscopic examination showed that tuberculous disease was commencing in the bladder round the orifices of the ureters. The left kidney, even, was not quite intact, but the urine from it was clear and was free from albumen. The patient's bladder was washed out with silver solution and tuberculin injected, at first 1/20 mg. in pauses of from four to eight days, increasing up to 0.5 mg. Larger doses than these at once set up active fever. The patient's general condition improved, she increased in weight, the cystoscopic condition improved, the bladder finally healed, the urine cleared, but still contained a few bacilli. This condition continued for about a year, during which the patient made a journey abroad, and during this time all treatment was suspended. The treatment was therefore broken off prematurely.

He would specially plead for a trial of treatment by tuberculin in cases in which the second kidney was not quite sound, where the renal affection was complicated by lung disease, and for employment in the after-treatment after operation, or as a preliminary course for the object of obtaining better results from operation. Sometimes patients declined operation, and then a trial should be made of it.

Hr. J. Israel was all for operation. The immediate results of operation were very good. Out of 112 nephrotomies for tuberculosis, the deaths in connection with the operation had been only 2 per cent., and the permanent results had been quite surprising. Even without tuberculin treatment there were remarkable ups and downs in the course of the disease, and sometimes even considerable improvements. No harm had generally been observed by the use of tuberculin when the dose of it had been increased gradually; but some observations had given him matter for thought. He had once seen a patient with renal tuberculosis who was undergoing a course of tuberculin treatment suddenly develop tuberculous peritonitis, a rare complication in tuberculous affections of the kidney, although the tuberculin treatment had been carried out by an expert. The patient died from her peritonitis in a short time. He had also seen another case get worse very rapidly. If used as a preliminary to operative treatment, valuable time was lost which might well be fateful.

Hr. Karo agreed with Israel's views, but he was of opinion that tuberculin was useful in after-treatment after an operation; at least, the wound appeared to heal better, and the bladder symptoms subsided more quickly.

Hr. Rosenthal spoke on the

Treatment of Syphilis by Arsenic.

He had treated 60 cases with it. The treatment was not reliable, and its early use did not prevent the outbreak of secondaries. The results obtained were not unlike those obtained from atoxyl, but the dose of the latter could be much increased. There was danger, however, in its slow elimination. Koch and others had seen blindness follow the use of large doses.

Arsenic had no specific action on the disease. It might be used where there was any idiosyncrasy as regarded mercury, or where a relapse had occurred shortly after a mercurial course in malignant syphilis, in combinations of syphilis with tuberculosis or carcinoma, and, generally speaking, wherever there was any contra-indication as regarded the employment of mercury. The danger of poisoning by arsenic was not to be neglected. A combination of arsenic and potash iodide might be serviceable.

AUSTRIA.

Vienna, Jan. 26th, 1908.

Chorea and Melanosis.

At the Pediatric meeting Grüner showed a girl, æt. 9, with arseno-melanosis after using about 40 grams, over 600 grs., in 16 weeks, with excellent results on the chorea. The form of administering this large quantity was Fowler's solution. His prognosis of the melanosis was favourable, as the colour was rapidly disappearing since the drug was withdrawn. Morbus Addisoni was the disease to be confounded with this, but the patches on the mucous membrane was absent in arsenio-melanosis and present in Addisoni.

Noorden thought the melanosis was a dangerous symptom of arsenical intoxication, and portended some troublesome sequelæ.

Eisenschitz thought propylamine a safer and more effectual drug for chorea.

Galatti said Simonini, of Modena, obtained excellent results from the use of paraganglin in this disease.

Artresia of Œsophagus.

Mathilde next showed specimens of narrow œsophagus from a child that lived three days. At the lower part of the channel the œsophagus communicated with the trachea, but at the pharynx end the œsophagus was quite occluded, the trachea lying back against the pharangeal wall. This occlusion extended down to the vocal cords, below which a sac was formed. When the sound was passed from the stomach it entered the trachea about the bifurcation, so that the œsophagus was along the trachea to the mouth.

Tandler said he had met with different forms of atresia. There was another more common form where fistulæ communicated at different points between the trachea and œsophagus.

Struma Stenosis.

Lieber presented a child, aged 14 days, who, after the first bath, was seized with contractions of the thyroid glands. After applying a pad and bandage to the neck the struma disappeared, but reappeared on its removal. After four days constant application the swelling has quite disappeared, leaving no symptom of stenosis.

Escherich said congenital struma after a warm bath was a common occurrence, as the moist head induced a great blood flux. He found the application of a piece of ice wrapped in cotton wool soon corrected this morbid condition.

Orthostatic Albuminuria.

Jehle read an exhaustive paper on the albuminuria of childhood, expressing a belief that this subject was far from satisfactory at the present time. He considered this form of albuminuria to be nothing more than an accentuated form of physiological albuminuria, and differing from pathological albuminuria depending upon a lesion of the kidney. Noorden characterises this form of albuminuria as diabetes albuminosus, while others have names attributing the changes to a variable blood pressure in the organ. Tubercle, syphilis, and other blood diseases are credited with the greatest share of blame, but all are yet shrouded in mystery. He presented six children with albuminuria, who passed albumen only when in the standing posture. When walking, running or sitting, no albumen was eliminated. The greatest amount was passed when the child stood up on its knees, but when it sat down on its ankles the albumen disappeared. The altered position of the spine also affected the constituents, as kyphosis of the lumbar region produced while lordosis suppressed it. If it stood with a slight bend, no albumen appeared, but when erect the albumen was present. If any of the patients were fixed in a bent posture with a belt round the groin and a cravat on, walking or standing were both alike—no albumen present; but immediately these bands were released the albumen appeared on standing. If the child be put up in plaster, albumen will be eliminated either standing or lying; if the lordosis in the lumbar region be reduced, the albumen disappears. It appears from these experiments that the lordosis is the primary cause of the albumen in these orthostatic cases. The natural lordosis in the third and fourth vertebræ is not so productive of albumen as the lordosis in the first and second lumbar vertebræ, hence any weakness in the lumbar muscles is likely to produce albumen. From this it is evident that pressure on the kidneys which interferes with the circulation of the blood is the proximate cause, and may thus be reduced to an anatomical lesion of the kidney. The proper treatment of orthostatic albuminuria, therefore, lies in correcting the anatomical lesion.

Noorden said the paper was a very interesting and instructive lesson on an equally obscure subject that had engaged many investigators during the last few years. This mechanical elucidation of orthostatic albuminuria was the best explanation he had got on the subject, but it did not explain all. Why, for instance, have we albumen in many cases only at particular hours of the day, such as the morning, and none in the afternoon? And why does acetic acid bring down such quantities? Strasser agreed with Noorden, and affirmed the albuminuria was cyclical.

Tandler showed a child with more than normal lordosis that agreed with Jehle's theory. He had no doubt that many adults suffered from this orthostatic albuminuria.

Escherich thought Jehle had progressed another step forward in orthostatic albuminuria which, according to theory, should be designated lordotic albuminuria.

Munnaberg was not satisfied with Jehle's explanation as orthostatic albuminuria soon corrected itself without considering the anatomical factor. Muscular strain, mental exertion, cold baths, shock, etc., all produce orthostatic albuminuria without lordosis.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

CHAIR OF CLINICAL SURGERY, UNIVERSITY OF EDINBURGH.—Pending the appointment of a new occupant of this chair, the University Court have arranged to ask Mr. J. W. Dowden to carry on the work of the class, as he had already been entrusted by the managers of the infirmary with the charge of the wards lately under Professor Annandale's care. Mr. Dowden has been in close touch with Mr. Annandale for a great many years, and the appointment as interim holder of the chair is regarded with satisfaction on all hands. Mr. Dowden is not a candidate for the vacant chair, though the majority of the other surgeons whose position renders them eligible are so. The future Professor, whoever he may be, will labour under the disability (if it ought to be called so) of holding the chair, not for life, but until he attains the age of 65. The reason for this is the age limit recently enacted by the managers of the infirmary. Whoever is appointed will have to give up his hospital wards at that age, and a Professor of Clinical Surgery who held no hospital appointment would be rather a contradiction in terms. No doubt this will influence the Crown in their choice, though, of course, two opposite views may reasonably be held on the matter—viz., that it is best to appoint a comparatively young man, who will hold the chair for a number of years, or that it might be better to have an older man who would energetically throw himself into the work, though for a less period. In any case, it may honestly be said that surgery in Edinburgh was never so well represented as it now is. The idea that surgery is the weak point in the school, however true in the past, is quite erroneous nowadays, and three names at least will suggest themselves to Edinburgh men as those of surgeons who would not only fill the chair to the satisfaction of everyone, but would lend it fresh distinction.

LORD LISTER AND THE FREEDOM OF THE CITY OF GLASGOW.—On Wednesday last, the 22nd inst., the freedom of the City of Glasgow was conferred on Lord Lister, who was unable to be present from advanced age and enfeebled health. The Lord Provost, Sir William Bilsland, alluded to Lord Lister's former connection with Glasgow, as Professor of Surgery in the University, and Surgeon to the Royal Infirmary, where he developed the antiseptic treatment of wounds He said it was exactly a century ago since Dr. Edward Jenner, the discoverer of vaccination, had a similar honour conferred on him.

Sir Hector Cameron represented Lord Lister, and read the following letter from his illustrious teacher:—"My Lord Provost,—The freedom of the city of Glasgow is an honour justly held in the highest estimation. I greatly regret that the state of my health prevents me from expressing in person my gratitude for this great distinction, and I appreciate very highly the kindness of yourself and your fellow-magistrates in offering to confer it on me *in absentia*. This is far from being the first occasion on which I have had reason to be grateful to Glasgow. Arriving there on my appointment by the Crown to the Chair of Surgery with only one personal acquaintance in the city, the late Professor Allan Thomson, I was welcomed with the utmost cordiality by my colleagues in the University, and received abundant kindness from the genial citizens of the Western Metropolis. Having been in due time elected by the managers of the Royal Infirmary as surgeon to that institution. I experienced uniform consideration at their hands when applying to the treatment of wounds the great truth which had been recently revealed by the illustrious Pasteur regarding the nature of fermentative changes in organic substances. That truth, though it seemed to me to shine clear as daylight from Pasteur's writings, was for many years not generally recognised; and thus it was my privilege to witness in my own practice, as the application of the principle became greatly improved, the revelation of pathological truths of fundamental importance and a revolution in practical surgery; and I look upon the years spent in your city as the best period of my life. The old infirmary is now giving place to more commodious buildings, and, great as must necessarily be the expense of this undertaking, I do not doubt that the proverbial liberality of Glasgow will prove fully equal to the occasion." The reading of the letter was received with applause.

INFECTIOUS DISEASES IN SCOTLAND.—A few fresh cases of small-pox have cropped up in Edinburgh and Leith; the total number of cases is now about 24. One or two patients have been notified as suffering from cerebro-spinal meningitis. In Glasgow the epidemic of enteric fever has not yet spent its force, cases still being reported though not in great numbers. There have been between 70 and 80 cases altogether. The outbreak has been traced to an infected milk supply.

RESIGNATION OF THE MEDICAL OFFICER FOR FIFE AND KINROSS.—Dr. Nasmyth's resignation has led to some discussion in the County Council as to the terms on which his office is to be filled. One section of the Council is desirous of appointing four medical officers, one for each section of the county; another section wish to have two medical officers. The total salary available being from £500 to £600 it is difficult to see how by multiplying the officials adequate remuneration could be given to each, and this view is evidently that taken by the Local Government Board, which is strongly against any return to subdivision of the county into areas and the employment of part-time medical officers.

MALADMINISTRATION OF THE FALKIRK FEVER HOSPITAL.—The charges of inefficiency and extravagance brought against the Falkirk Fever Hospital by Mr. Miskimmin were the subject of a public inquiry by the Sheriff of Dumfries and Galloway and Sir Henry Littlejohn. The inquiry has not yet been completed, and the report is not yet made public. A great deal of evidence of a very disquieting nature was however given. Convalescent scarlet fever and enteric patients deposed to having been allowed out of the hospital while still under treatment. Dr. Clarkson, one of the leading practitioners in the town, animadverted strongly on the carelessness of the nursing, and instanced the case of a diphtheria patient who contracted typhoid while in hospital. There was no night staff, and the matron and nurses were sometimes out at the same time. Accounts were given of concerts and card parties held in the hospital at unseemly hours, and there were numerous complaints as to lack of nursing, the quality of the food, irregularities in carrying out the medical treatment ordered; the bright spots in the lives of the patients apparently being the absence of any irksome restrictions based on ideas about isolation, and the abundance of tobacco at their disposal. Perhaps the most serious irregularities were those alleged of allowing a case of small-pox to walk to the hospital, and a convalescent typhoid case to have a substantial meal containing such dainties as roast beef, cabbage, new potatoes, and stewed rhubarb. This was said to have been done in defiance of the medical officer's order, and it is lamentable to state that the patient died on the following day. No doubt the upshot will be that the hospital will now be put on a thoroughly satisfactory footing, but only those who know how long it takes to restore the confidence of the public in an institution after such allegations, can estimate the harm done.

THE LATE PROFESSOR SIR THOMAS MCCALL ANDERSON.—We regret to announce the unexpected death, on the 25th inst., of the distinguished Regius Professor of Medicine in the University of Glasgow, representative of the University on the General Medical Council, and the holder of many other important public appointments.

BELFAST.

VISIT OF SIR VICTOR HORSLEY.—On Thursday last a fine example of the strenuous life was set by Sir Victor Horsley. During a visit extending to just twelve hours he delivered three addresses. The occasion of his visit was the Jubilee celebrations of the Irish Temperance League, and when invited to attend these meetings he consented on condition that the chief meeting should be largely a medical one, the chair being taken by the President of the Ulster Branch of the British Medical Temperance Association, Dr. Calwell. This was arranged, and the chair was so filled. At this meeting Sir Victor dealt with the drink problem from the national standpoint, advocating high licenses and local option, and showing how these two agents promoted temperance in other countries. A vote of thanks was moved by Dr. McMurtry (a pioneer of the temperance movement in Belfast), seconded by Sir John Byers, and conveyed to the lecturer by Professor Sinclair, who took the chair when Dr. Calwell was obliged to leave. At an afternoon meeting for ladies, Sir Victor gave an address on "The Use of Alcohol in Health and Disease," advocating the view that it is a narcotic drug, and specially harmful to young people. He would abolish it entirely from the table, and did not consider it indispensable as a drug, its place being easy to fill. The Ulster Branch of the British Medical Association took advantage of Sir Victor Horsley's visit to invite him to address their winter meeting, which was held in the Medical Institute in the forenoon. To a large meeting, presided over by Dr. Warnock, of Donegal, he delivered a most thoughtful and stimulating address on "The Early Diagnosis of Intracranial Conditions Requiring Surgical Interference." He dealt specially with the very early disturbance of tactile sensation, the means of discovering it, and the lessons to be learned from it. The address was a model of lucidity, and beautifully illustrated with lantern photographs and diagrams. At its close a vote of thanks was moved by Professor Sinclair, seconded by Dr. St. George, of Lisburn, and passed by acclamation.

DEATH OF DR. TAGGART, OF ANTRIM.—The death of Dr. Taggart in his seventy-fifth year removes a well-known medical man from Antrim. He was born at Randalstown, Co. Antrim, in 1833, and entered the ministry of the Presbyterian Church in 1855. After some years' ministry in Australia, he returned to Ireland, studied medicine, and graduated M.D. in 1864. He settled in Antrim, only a few miles from his native place, and there he practised till his death. He was for many years the Medical Officer of the dispensary district. Though he had retired from the ministry of his church, he continued to take the warmest interest in it, acting as an elder, teaching in the Sunday School, and helping generously in all good works. He had travelled and read much, and was a keen observer, so that his mind was highly cultured. He was held in high esteem by all classes and creeds, and he will be much missed.

LETTERS TO THE EDITOR.

INHERITED SYPHILIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have been much interested in the address by Mr. R. Clement Lucas on the above in THE MEDICAL PRESS AND CIRCULAR of January 1st, 1908, and the subsequent letters by Dr. Walsh and another. I observe that Mr. Clement Lucas speaks of Colles' law. In this respect the clinical observation that a diseased child born of a mother who is without any obvious venereal symptoms may infect the most healthy nurse, but is rarely known to infect its own mother, is usually associated with the name of Colles, and is universally referred to as "Colles' law."

But some time ago, in the columns of the *Lancet*, February 25th, 1899 ("Colles' Law" or "Wallace's Law"?), I drew attention to the facts in support of the claims of another distinguished surgeon, W. Wallace, whose oral lectures in Dublin had appeared and were appearing in the *Lancet* of 1833-7, in which later observations of Colles occur independently. Some of these observations—*e.g.*, the acquisition of disease by the "dry" nurse and in "wet" nursing appeared in the *Lancet* of February 13th, 1836; others, viz., the contagious nature of the two forms of disease (hereditary and acquired) in the infant; the acquisition of disease from a strange child "not her own child," and apparent freedom from disease in the mother of a diseased infant appeared in the *Lancet* of May 7th, 1836, which was before the publication of Colles' work, dated January 20th, 1837.

A review of Colles' book appeared in the *Lancet* of March 25th, 1837.

"What could have induced the worthy gentleman, who considers himself—sad mistake—to be the 'author' of its contents, to put forth such a *cruda indigestaque moles* in 1837? Is the practice going down in Dublin, and are the Irish public in want of the reminiscence? It must be so . . .; not a fact is contained in the whole volume which has not either long since been published or been preceded in print by a similar fact as appositely told . . . we would undertake to prove that all the facts contained in a chapter on 'Syphilis in Infants,' which occupies more than forty pages, and certainly is the best chapter in the book, will be found in almost as many lines in the lectures and remarks delivered by Dr. Wallace on this subject, and recorded in the *Lancet*. In short, we regret, for the credit of English medical literature, to say that the whole volume is a crude jumble of facts with which, and with many more, all intelligent practitioners are already acquainted. . . Unless, in short, the conjecture already expressed affords some explanation of the birth of this volume, we must abandon the task of guessing at the object of its publication; but we are the more disposed to believe our opinion to be well founded from the fact that Dr. Colles has taken especial care to keep from the public eye in his pages the names both of Carmichael and Wallace, brethren residing in the same city, highly appreciated there, and well known wherever British medical literature has reached."

In the *Lancet* of May 20th, 1837, Wallace deals more especially with the freedom of the suckling mother from the disease of her own child. He states that by means of many cases he had been led to the discovery of an important law—viz., that, as soon as the constitution of any individual becomes contaminated with this poison, all parts of his body are rendered insensible to inoculation with the matter of his own sores or of analogous sores of another individual, as an example of which he alludes to the fact that he had never seen a mother injured by her own disordered child. "You may say she was sound. I admit she was so to external appearance, but you have, in my opinion, a proof in her having given birth to an unsound child that she was unsound. . . . In the present state of pathological science few will refuse to admit the originality of these views; but they will surely attach to their author an epithet, in their opinion opprobrious. They will describe him as a speculatist. So they may. My speculations are only the general expressions of the facts I have witnessed. Half a dozen of years will not, I am convinced, pass by until they shall be generally admitted as immutable truths, as laws of Nature; and then, most probably, if I am not beyond the din of this sublunary planet, they will find a father in some other quarter."

In 1838 Wallace was beyond the "din," but his work remains, if universally unaccredited.

In my article, however, I stated that "the question of priority was of minor importance in comparison with the observations and interpretations of Wallace," which I maintained therein and independently elsewhere (*a*) on behalf of the primarily contaminated and untreated mother. And now, to my great pleasure, in confirmation of Wallace, as I conceive it to be, Mr. Clement Lucas independently holds that "inheritance from the father alone is put now entirely out of court,

---

(*a*) **"On Maternal Syphilis, including the Presence and Recognition of Syphilitic Pelvic Disease in Women." By J. A. Shaw-Mackenzie, M.D.Lond., 1898. J. and A. Churchill.**

that it follows that infection of a mother by her syphilitic fœtus can never occur, that inheritance is invariably through the syphilised mother."

Yours faithfully,

J. A. Shaw-Mackenzie, M.D. (Lond.).

TRYPSIN AND CANCER—THE QUESTION OF PRIORITY.

To the Editor of The Medical Press and Circular.

Sir,—May I apologise to you, your readers, and especially Dr. Shaw-Mackenzie, for my delay, through an oversight, in answering your article of December 4th regarding this question?

The question of priority is of very minor interest to me personally; and this not for the obvious reason that certainly I have made no discovery, but because my ruling desire now, as for nearly two years past, is simply to get trypsin used, as I think it should be used, in every case of malignant disease, at whatever stage, and whatever other treatment be or be not employed. As regards priority of idea, I think Dr. Beard has it, as I try to show in my book; but that is his personal affair, and I shall make no attempt to urge the point now. As regards priority of act or practice, there has never been any question as to Dr. Shaw-Mackenzie's claim, surely! On page 68 of my book I say that "to him, undoubtedly, must be awarded the credit of being the first physician to employ the new treatment." The word physician had better been "person," perhaps, since I might have conceivably meant some reservation as to a surgeon—or Dr. Beard, as now occurs to me; but, of course, I did not. I take it for granted that trypsin was never injected into a human being (except unknowingly, I suppose, in injections of blood) until Dr. Shaw-Mackenzie did so, as he tells us, in January, 1905. Dr. Beard, of course, is "not even a medical man," as some king of thought, who must surely have heard the name of Pasteur, said somewhere in the attempt to decry the new treatment; and, having no patients of his own—nor ever having had any—he has no conceivable claim to priority of practice.

Dr. Shaw-Mackenzie's practice I believe to be based upon an erroneous theory (that trypsin digests glycogen), but that is neither here nor there. Neither my book, nor anything I have ever written anywhere, contains the smallest vestige of personal abuse, or anything remotely resembling it, of Dr. Shaw-Mackenzie, who is unknown to me, but, of course, has my best wishes on general principles.

And now a word, which I am sure you will allow me, as to myself. There is obviously no altering the fact that I have had a medical education, have taken a medical degree, and was registered on the same day, as usual. I have also practised medicine in hospitals and—to the extent of, I think, three patients—privately. Two of these paid me—about the usual percentage, I am given to understand. But I do not practice medicine, and have not done so for some four years. You mention my "professional brethren," but my professional brethren are authors in general and also lecturers. If I owe professional allegiance to anybody, I suppose it is to the Authors' Club, to which I belong. My case surely cannot be so peculiar; there must be other men, holding medical qualifications, who are yet not members of the medical profession. You say I am "generally understood not to be engaged in actual practice." (I don't know whether the adjective is meant to weaken or strengthen the noun, but, at any rate, I do not practice in any shape or form.) True, I have paid scores of visits to cancer patients during the last two years, and have seen any number of injections made, but always with the practitioner in charge, and always, of course, without fee. There has been some paying, but it has been the other way; nor can I imagine that anyone who has seen the beneficent results I have seen would hesitate to do what he could to enable poor people to participate in them, even though almost the whole medical profession was loading him with personal abuse meanwhile.

However, I fear your statement as to the general understanding is scarcely correct, even though I must have stated in twenty articles and from scores and scores of platforms that I don't practice. Yet one of the burdens of my existence is to deal with the correspondents who, rarely enclosing stamps, want to consult me—foolishly enough, no doubt, but one is bound to answer them, nevertheless.

I have even drafted an advertisement for the *Daily Telegraph* and *Daily Mail* to state that I don't practice, and cannot earn my living for this nuisance of correspondence and telegrams, and even people calling; but such advertisements would have been too ridiculous, and would have endeared me to few.

Here, however, let it be publicly said, for what feels like the ten-thousandth time, that I don't practice, won't practice, have lost any capacity I ever might have had to practice; yet, also that any medical man whom I can serve in any way as regards the ferment treatment of cancer has me freely at his service until such time as I can leave for ever the most expensive and sleep-destroying business I have ever had anything to do with, and can proceed with my own literary interests, which are in the main sociological.

There is still on the bookstalls a little volume of mine which seems to sell, though I have no interest in it, and which you were good enough to praise some years ago. Its chapters were written anonymously, when I was a literary beginner, for the *Pall Mall Gazette*; and, picking it up the other day for a reference, I was horrified to find the phrase "my patients" on the first page I opened. Whether these were the dauntless three, or hospital patients, I don't remember; but, at any rate, I had ceased to practice before the booklet appeared with my name.

Any of your readers is welcome to interrupt my work any morning by calling at my house, and if he can find a stethoscope or a clinical thermometer on the premises he may have it as a present, and I will never write another line.

I am, Sir, yours truly,

C. W. Saleeby.

13, Greville Place, N.W., January 20th, 1908.

[Our further criticism of Dr. Saleeby's attitude is a graver one—namely, that he has appealed to the public through the lay Press in sensational articles to judge of the value of a method of treatment which is still *sub judice* among medical men who have the opportunity of forming an opinion. We regard it as more than cruel to lead patients suffering from so terrible a disease as cancer to have recourse to any treatment other than thorough surgical means, except in inoperable cases. The effect of placarding the newspapers with praise of a medical treatment cannot but be to lead nervous and anxious people to dally with it till the golden hour has passed. Our columns are open to any record of scientific evidence in favour of any rational method of treatment, and no one would rejoice more than ourselves if the ferment treatment of cancer proves of substantial value to humanity.

Two-thirds of Dr. Saleeby's letter is devoted to a personal issue, and would have been quite as effective if couched in a single sentence. He admits Dr. Shaw-Mackenzie's priority in practice, but denies his priority in theory, because he, Dr. S., does not agree with that theory. It is to be hoped that Dr. Beard will be able to furnish a more satisfactory answer to our challenge of December 4th, 1907, as to the priority of the trypsin method in cancer.—Ed.]

MALIGNANT ANTI-VIVISECTION FANATICISM.

To the Editor of The Medical Press and Circular.

Sir,—As a dog returns to its vomit and a fool to his folly so the fanatical victim of a fixed idea iterates and reiterates the lies his morbid imagination has evolved, or emits and repeats his own version of the falsehoods he has taken in from the utterances of his brethren. The psychology of the anti-vivisection fanatic has afforded an interesting study. The letters I have evoked confirm the opinion generally formed of the mental calibre and the moral state of these poor creatures. They are really more to be pitied than many inmates of our asylums, the victims of delusions much less painful to themselves than those of these wild fanatics. An anti-vivisectionist who really believes in the lies he utters, and, sensitive as he professes to be, realises mentally the scenes of torture he depicts, must live himself in continual torment. He is, indeed, very often on the way to the lunatic asylum; he has, at any rate, the mind and the temperament which lead thither. Could anyone but a hopeless fanatic write in cold blood that it is impossible for a humane man to become a vivisector, and that vivisection is in the last degree demoralising? A mad libel on the illustrious dead and living; upon the elect class who in a money-grubbing and selfish age have devoted themselves, and are still giving up their lives, with complete self-sacrifice, to the service of humanity. In conferring the freedom of Glasgow upon Lord Lister and other distinguished men on Tuesday last, the Lord Provost said that "Lord Lister's name would have an imperishable place among the greatest and noblest benefactors of humanity." Lord Lister we have happily with us; many of us know him, or even claim him as a personal friend. We are able to appreciate the foul aspersions which malignant anti-vivisection fanaticism flings at him and the great band of noble figures, living and dead, who have wrought in the same field, and helped not only to lessen enormously the mass of human pain, but also to advance the knowledge of nature upon which the progress of mankind depends. The injury arising from the rabid propaganda of these fanatics is falling, as usual in such cases, on the ignorant crowd, upon the masses, too dull to reason and incapable of receiving any mental impression save from the repetition of a crude, coarse statement. They do not know—they cannot understand—the meaning of science; but, if the statements are sufficiently and continuously forced upon their attention, especially by those they look upon as educated gentlemen, they will believe that experimental physiologists are all anti-human wretches, and the medical profession, their pupils, a crew of heartless tricksters. Now comes the opportunity of the cynical quack. We are witnessing now the apotheosis of the quack—a whole army of impostors amassing wealth by the deception and plunder of suffering humanity. Tens of thousands of the poor and ignorant, wrought upon by anti-vivisectionists, are refusing the help that scientific medicine and surgery can so often surely afford, and are going to death through prolonged anguish, which might have been prevented, or mitigated, by science. For this mental and physical suffering—a million times greater than the terror and pain inflicted by physiological experiment, even if these were as great as the fanatics declare—the mad leaders of the innocent, ignorant crowd are alone responsible.

I am, Sir, yours truly,
A SURREY DOCTOR.

January 23rd, 1908.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent "A Surrey Doctor" evidently knows little of vivisection. He should study the medical journals (especially the *Journal of Physiology*), the Report of the Royal Commission of 1876, the "Confessions of a Physician" by "Veresaeff," and other works on vivisection, in which he will find ample evidence of the cruelty and the demoralising effects of the practice of experimenting upon living creatures. His own letter supplies additional evidence of this. It is full of prejudice and passion, and shows how he would like to silence his opponents if he could. But the British people (especially the working classes) are finding out what vivisection really is, and I believe the time is not far distant when this immoral and dangerous practice will be strictly prohibited and suppressed by law. I enclose my card, and remain,

Yours faithfully,
Hove, January 23rd, 1908. A. V.

THE *STAR* AND THE MEDICAL PROFESSION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I understand from the sentence which you have allowed your correspondent to include in his letter ("it is [illegible] unnecessary to continue a controversy in your pages") that you do not desire the controversy he commenced to be continued. For, of course, the decision rests with you, and not with him. But I hope you will permit me to say that my reference to the vaccination of one-day-old infants "before the reduced fees came into operation" was not, as he says, an innuendo but an admitted fact. The evidence is to be found in the report of the proceedings of the Aston (Birmingham) Guardians on December 17th, before whom two medical officers, charged with this offence against humanity, appeared and allowed the charge to go without defence.

The other statements of "A Surrey Doctor" also confirm my previous suggestion that the profession err in ignorance, for he puts forth as truth what a greater knowledge of the subject would show him to be the very matter in controversy. It may be that Prof. Crookshank's work was "discredited years ago." It was never answered. The misfortune is that like "A Surrey Doctor," so many are willing to discredit rather than to investigate or disprove.

And my point as to compulsion remains untouched.

Yours, etc.,
THE EDITOR OF THE "STAR."

[We are sorry that the sentence quoted from "A Surrey Doctor's" letter should be thought by our correspondent to mean that we do not wish the controversy to continue. "A Surrey Doctor" was expressing his own view, not ours. Anything within reasonable limits of space (and to the point) we shall be most happy to publish.—ED.]

THE PROPOSED INQUIRY INTO THE ACTION OF ALCOHOL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—If you will be good enough to read the communication which you received on the proposed inquiry as to the action of alcohol in pneumonia, I think you will see that you have done the International Union of Medical Abstainers an injustice. This inquiry is proposed by those who doubt the value of alcohol, but the whole profession are asked to conduct it and to furnish the results. I presume you do not wish to imply that the results will be tampered with.

As to the scheme which you deprecate, it seems clear that if a sufficiently large series of consecutive cases are treated, odd cases with and even cases without alcohol, the comparison would be as fair and thorough as could be arranged. But I agree with you that this plan verges on the immoral, and, though certain Continental physicians see no objection to it I urged that an alternative plan might be allowed (Plan B.), which you do not mention, a plan more suited to English ideas, and my colleagues agreed to this. In this alternative plan the physician administers alcohol, or withholds it, as he thinks proper, and tabulates the result. This is not so crucial as Plan A., as possibly the severer cases are more likely to get alcohol, but it is scarcely fair to us that you should ignore it. I trust you will do us the favour of inserting this letter in your next issue.

I am, Sir, yours truly,
J. J. RIDGE.

[We publish Dr. Ridge's letter with pleasure. We do not think anyone reading our note would gather that we suggested *dishonest* tampering with results; we meant simply the unconscious bias which the leaders of a partisan movement necessarily possess in favour of their cause, and which is fatal to the serene dispassionateness that should pervade a scientific inquiry. Plan A. fully illustrates our point. We did not mention Plan B., first, because it was not possible in a short note to deal with every point; secondly, because it was subsidiary and not the main plan; thirdly, because in so far as it was in point, it did not seem open to any particular criticism. Our readers will not suspect us of wishing to do any injustice to the cause of temperance, which we have championed so frequently.—ED.]

CHRISTIAN SCIENCE AGAIN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read the note, "Christian Science Again," in your issue of the 15th inst., and I feel sure that the very strength of your antagonism to Christian Science will gain admission to your columns for this letter, because I believe that that antagonism is not divorced from a wish to be absolutely fair. May I say at once that the only thing that could seriously affect the growth of the Christian Science movement would be dishonesty on the part of Christian Scientists, and that it is therefore of paramount importance to Christian Scientists that there should be nothing to hide in the working of Christian Science. Mrs. Davidson called in a doctor, in perfect good faith, as the full report of the case shows, after the death of the patient. It is possible that she made a technical mistake in not reporting the death to the Coroner instead, but it cannot be pretended that she attempted to "unload" her patient.

There is a law, and a very necessary law, that inquests should follow deaths, under certain conditions. I am not aware that Christian Scientists have ever attempted to "burke" this law. I could, on the contrary, produce cases where nothing would have been easier than for those concerned to do so, but where they have deliberately elected to go into the coroner's court rather than hide anything.

I believe I may claim as wide a knowledge of the Christian Science movement in this country as anybody connected with it, and, so far from making "a wonderful amount of money out of it," I hardly know anybody who has succeeded in getting a bare livelihood out of it. Christian Science workers are nearly all either in possession of private resources or working hard by day for the means to support themselves, so as to be able to devote their spare time to the sick and sorrowful.

As to Christian Science being unscientific and blasphemous, that is a colossal generalisation which the world, as it learns more and more what Christian Science is, is less and less moved by. If it is unscientific to make absolute truth your aim, to endeavour to demonstrate your premises in the most practical manner, it may be the first; if it is blasphemy to accept Christ as the Way, and to strive to walk in that way, it may be the latter.

I am, Sir, yours truly,

FREDERICK DIXON.

London, January 24th.

THE SOCIETY OF MEDICAL PHONOGRAPHERS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is many years since the Society of Medical Phonographers was last mentioned in your columns, and we shall be glad if you will allow us to direct attention to the fact that it still exists and still issues its medical periodical in lithographed phonetic shorthand. We believe that many members of the profession are ignorant of the Society and its efforts to promote the effective use of shorthand in medicine, both in practical work and in research.

The Hon. Secretary will be glad to furnish particulars of the Society to any members of the profession or students who may desire to join it.

We are, Sir, yours truly,
WILLIAM R. GOWERS, President.
G. SIMS WOODHEAD, }
C. W. CATHCART, } Vice-Presidents.
ASKAR C. GRUNER, Hon. Secretary.
Pathological Department, General Infirmary,
Leeds, January, 1908.

MOTOR-CARS FOR MEDICAL MEN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the interesting account which you give of the recent exhibition of motor-cars in Dublin, you say rightly that the most important part of the show for the majority of the medical profession was the "small cars." You, however, omit to go a step further, and say what is the best "small car" for a country practitioner. Of course, I can understand the difficulties which lie in the way of a medical journal definitely recommending one car to the disadvantage of its rivals, as it might be accused of favouritism, and therefore, I do not ask you to make a selection. Perhaps, however, some of your many motorist readers would do so, and would inform a brother practitioner as to what car they consider most suitable for everyday use in a country district where roads are bad. The car may be a two or a four-seater, as is thought best, but it must be of moderate price, economical in its up-keep, and reliable.

I fully share—what is evidently your belief—that the time is near at hand when the country practitioner can definitely abandon horses in favour of a more speedy, more reliable, and, for its mileage, more economical means of locomotion. But, even if the time has already come, much depends upon the car, and if, in addition to giving the name of the most desirable car, my charitable informant will also add some particulars as to the cost which he has personally incurred in its up-keep, he will place me still further in his debt. Perhaps I should simplify his task if I ask a definite question. Is there any make of small car which could be run at an average of, say, 15 miles a day, or 5,000 in the year, at a cost of £50 a year, not counting the wages and keep of a man for looking after it, should such be employed?

I am, Sir, yours truly,

M. D.

ADMISSION OF WOMEN TO THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your editorial note on this subject in your last issue states that "under existing circumstances the licence (of the College of Physicians) cannot be given apart from the membership of the Royal College of Surgeons of England, as the two qualifications are now conjoint and indivisible." Is this really so? Or, has not the College the power to grant its licence to any registered medical practitioner? Such a power is possessed by the Irish College, and it seems strange that it should not also be possessed by the sister College in London.

I am, Sir, yours truly,

L.R.C.S.I.

OBITUARY.

SIR THOMAS McCALL ANDERSON, M.D.GLASG., F.F.P.S.GLASG.

WE regret to record that Sir Thomas McCall Anderson, Regius Professor of Medicine in the University of Glasgow, and an Honorary Physician to the King in Scotland, died suddenly on Saturday while attending a dinner of the Glasgow Ayrshire Society in St. Enoch's Hotel. He had proposed the last toast of the evening, and the company was dispersing. He had only descended a few steps of the hotel stairs when he was seized with heart failure, and expired in a few minutes. Born in 1836, Sir Thomas studied in Edinburgh and Glasgow, graduating with honours in medicine at Glasgow University in 1858. He afterwards continued his studies in many of the celebrated schools and hospitals on the Continent of Europe. His first appointment was that of Lecturer on the Practice of Medicine in Anderson's College. When the Chair of Clinical Medicine was founded in Glasgow University in 1874, Sir Thomas was its first occupant, and he held the office for 26 years. In 1900 he succeeded Sir William Gairdner in the Chair of Practice of Medicine. His success as a teacher was due to his systematic mode of expression and to his powers of organisation. As a physician he was a good practical and sagacious adviser. His powers lay perhaps more in the direction of therapeutics and treatment rather than in the direction of pathology and the more intricate problems of diagnosis. As a dermatologist Sir Thomas was widely known, not only in this country, but in America and in Europe generally, and his writings upon the subject have enjoyed a large circulation. As a consultant for a great many years he enjoyed a very extensive practice. The clearness with which he expressed his views as to diagnosis, and the thoroughly practical manner in which he initiated treatment, commended him to a large circle of his professional brethren. Some two years ago he received the honour of knighthood.

ST. GEORGE C. REID, M.R.C.S.

WE regret to announce the sudden death, at his residence at Thornton Heath, of Dr. St. George C. Reid, at the age of 48 years. Dr. Reid, who was bacteriologist to the Central London Throat and Ear Hospital, besides having an extensive local practice, was Consulting Surgeon for Diseases of the Throat and Ear to the Croydon Infirmary, and Secretary to the British Laryngological Association. In early life he had served as Surgeon in the Russo-Turkish War, for which he held the medal.

SPECIAL ARTICLES.

THE NOTIFICATION OF BIRTHS ACT IN SCOTLAND.

THE Aberdeen Town Council met in the Town Hall on the 20th inst., the Lord Provost, Sir Alexander Lyon, presiding, and received a deputation of medical men consisting of Dr. Williamson, president of the society; Dr. Marnoch, secretary; Dr. Lister, treasurer; Dr. Edmond, Dr. John Gordon, and Dr. M'Kerron.

THE SOCIETY'S MEMORANDUM.

Dr. Williamson read the society's memorandum as follows:—The Aberdeen Medico-Chirurgical Society, having on various occasions considered the terms of the Notification of Births Act, unanimously resolved at a meeting held on the 9th inst. to ask the Aberdeen Town Council to receive a deputation from the society, who should lay before the Council the special points in the Act which appear to the members of the medical profession to be objectionable, and to ask the Council's consideration of those points before deciding on the adoption of the Act. While desirous of submitting the following objections, the society desire it to be clearly understood that its objections are not directed against the principle underlying the Act, which they consider a good one, calculated as it is to reduce infant mortality; but they most strongly object to the method of working the Act, in so far as it lays on medical men the burden of notifying births at which they have been present, and that under a penalty if they fail to do so.

1. Medical men feel that it is not necessary that the burden of notification should be laid upon them, but that the proper person to be charged with such a duty is the father, whom failing the nearest relative or person in attendance on the mother. The argument has been used that it is the duty of medical men to notify infectious disease, but the society wishes to point out that the two Acts are not analogous. In the case of the Infectious Diseases Act (1889) a skilled opinion is given, and can be given only by a medical man; whereas in this Act it is merely a statement of fact which is asked for, and which can be intimated by any person in the house; further, in the case of infectious disease there is a serious risk to the public health, and to prevent this risk the case is notified. There is no risk to the public health in a case of child-birth.

2. Further, there is nothing to be gained by compelling medical men to notify. The main idea underlying the Act is that the Public Health Department would come into touch with children shortly after birth, and give instructions as to the proper rearing of the child; presumably such instructions would not be given where there was a medical attendant, consequently there can be no advantage in getting notification from medical men.

3. It is altogether contrary to the usage and best traditions of the medical profession for a medical attendant to give any information whatever regarding his patient, except in cases where the law requires an expert report in the interests of the public welfare, and, therefore, should a parent dissent from the notification of a child's birth, the medical man is professionally bound by these traditions to respect his wishes. Already a large number of births occur where no medical man is present, and should the Act be adopted, this number is likely to be increased, inasmuch as parents who desire secrecy as to the birth of a child would attain their object best by procuring unprofessional services, thus exposing both mother and child to needless risk. The chief purpose of the Act would in such cases be defeated.

4. The society would further draw the attention of the Town Council to the fact that, though the Act, as it stands, makes it compulsory for medical men to notify, there is no provision for any remuneration for giving such information, while the neglect of notification is a punishable offence. Medical men voluntarily do much of their work gratis, but to make the neglect of gratis work an offence punishable by law appears to the society to be scarcely within the bounds of common justice.

Should the Town Council of the City of Aberdeen decline to adopt the Notification of Births Act in its present form, as some other important corporations have done, the Aberdeen Medico-Chirurgical Society believes that such an action may draw the attention of the Government to certain anomalies in the Act, and thus lead to such revision as would make the Act of real service to the public health and acceptable to the medical profession, whose co-operation is essential for the successful attainment of the object—namely, a reduction of the present excessive mortality of infants.

LABORATORY NOTES.

MOSTELLE GRAPE JUICE.

WE have submitted to a chemical analysis a sample of the Red Mostelle Grape Juice, as supplied by the Grape Juice Company, Limited, of 7, Great Tower Street, London. This Grape Juice is the pure juice of sun-ripened Spanish grapes, prepared in Spain in such a manner as to leave all the constituents of the ripe grapes unaltered by fermentation or boiling. Our analysis of the red variety of Mostelle shows it to contain the following constituents:—

Extractives	21.40 per cent.
Mineral matter	0.28 ,,
Acidity as tartaric acid ..	0.69 ,,
Salicylic acid	absent.
Foreign colouring matter	absent.
Alcohol	absent.

There is present in the extractives a large percentage of the sugar derived from the grape, and our analysis shows that this juice is free from adulteration, being, as represented, the pure juice of the grape, free from alcohol, and preserved by sterilisation. We think that this juice forms an admirable temperance beverage, being delicious when taken either plain or with the addition of aerated water, and, quickly assimilated, it should form a valuable tonic drink in many cases.

Two other varieties of Mostelle are made—White and Golden Muscat.

METCHIKOFF'S "SANERIN."

THE latest product of Messrs. Allen and Hanbury's ingenuity is of more than ordinary interest. It is a tablet called "Sanerin," which is derived from a pure culture of bacillus acidi lactici. "Sanerin" is confessedly the outcome of Metchnikoff's work on old age, and if his theories be well grounded, it may prove the very elixir of life. The tablets may either be taken after meals in the usual way, but the more useful way, it is suggested, is for them to be employed to curdle milk, and for the soured milk to be drunk. The idea is that the lactic acid bacillus lives in and produces an acid medium, and its presence in hardy growth, therefore, is inimical to the presence of nearly all other organisms. Besides producing longevity, it is claimed for "Sanerin" that it is beneficial in diarrhœa, intestinal indigestion, and many similar cases.

"TABLOID" QUININE COMPOUND.

MESSRS. BURROUGHS AND WELLCOME have sent us samples of the above product. Each contains:—Cinchona alkaloids, 1 gr.; antifebrin (acetanilide), 1 1-5 gr.; camphor monobromate, 1-5 gr.; powdered ipecacuanha, ⅛ gr.; cascara sagrada extract, ¼ gr. This combination, it is suggested, is especially valuable at the present season, when changes of weather involve the risk of rheums and catarrhs. The antiseptic, anti-pyretic, expectorant and laxative principles of the compound quinine tabloid should help the patient to combat the infection and cut short the febrile process.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT MEDICAL LITERATURE.

Epidemic Pneumonia.—Fabyan (*Bull. Johns Hopkins Hosp.*, Dec., 1907) reports an epidemic of acute pneumonia in a family of ten within ten days. Six of the ten had definite signs of lobar pneumonia. Two others, including the father, who was the first one sick, gave a typical enough history of pneumonia, but had recovered before they were examined. Only one case was fatal. Pneumococci were recovered in this case, both from the blood during life, and from the blood and consolidated lung at autopsy. On careful examination of the home surroundings, no special etiological factors were found to account for this unusual contagiousness of pneumonia. D.

Motor, Sensory and Vaso-Motor Symptoms Arising from Coronary Sclerosis.—(*Mun. Med. Woch.*, Oct., 1907.)—In the observation of a large number of cases of angina pectoris, Schmoll has found that the symptoms may be divided into sensory, motor, and vaso-motor manifestations. These are:—(*a*) Sensory pain, a feeling of impending death, numbness of arm, or arm and leg, etc.; (*b*) motor—irritative or paretic; contraction of the intercostal, pectoral, or abdominal muscles on the one hand, weakness of the left hand and arm on the other; (*c*) vaso-motor—the left arm or the left half of the body may be blanched during the attack, owing to a contraction of the vessels of the part. Between the attacks these manifestations are less marked, but they are still present, if sought for carefully. Hyperæsthesia of the skin over the area of pain during the attack, slight weakness of the part, blanching or cyanosis between the attacks, are almost the rule. These symptoms can be traced to one or more spinal segments, usually between the eighth cervical and second dorsal. Schmoll accepts Mackenzie's theory that the irritation proceeding from the heart along the sympathetic to the spinal cord sets up an irritation there, which in turn is referred to the periphery. D.

Treatment of Whooping-Cough.—Kilmer (*Jour. Am. Assoc.*, Dec., 1907) reports a series of 550 cases of whooping-cough treated by the abdominal belt. Thse cases represent the observations of some thirty pediatricians. Most of the observers testified to the almost constant benefit noticed regarding the cessation of vomiting and moderation of cough It is in no sense a curative procedure. The belt is made of linen, with a strip of silk elastic webbing two inches wide inserted in either side. The belt laces in the back, and is worn over the undershirt. The width is four to eight inches, depending on the size of the child. The length is about three inches less than the circumference of the child's abdomen at the navel. At first only slight constriction is used, which is increased until the vomiting is controlled. D.

Paroxysmal Tachycardia.—Schmoll's article (*Am. Jour. Med. Sciences*, Dec., 1907) is an attempt to show that in paroxysmal tachycardia we have to deal, not with a single pathological entity, but with at least four groups as follows:—(1) Cases in previously damaged hearts; (2) cases from dysthyreosis; (3) cases with lesions of the central nervous system; and (4) cases of apparently functional character. The condition is characterised by attacks of suddenly appearing tachycardia, lasting ten or fifteen minutes up to five days, ceasing as suddenly as they began. In the attack the heart rate is either double or four times the normal. Cases are described showing how these features may occur in connection with each of the etiological factors mentioned. Most attention is directed toward the so-called idiopathic or functional cases. These were carefully studied by means of tracings in the attempt to explain the occurrence of the increased heart rate upon physiologial grounds. Through these tracings it is made evident that the tachycardia is the result of extra systoles, in some instances apparently originating in the bundle of His and involving only the ventricle, and in other instances by the presence of an auricular wave, more probably originating in the venous sinus. D.

Pathological Tissue Changes after Injection of Alcohol.—Baumgarten (*Berlin Klin. Woch.*, 1907) has made a large number of observations on animals after subcutaneous injections of alcohol. No local necrosis or abscess formation was found at the point of injection. Further, no formation of new connective tissue in the liver or elsewhere was noted. He did find, in many cases, erosions of the mucous membrane of the stomach and intestines. From these experiments the author suggests that alcohol is not a causal, but a predisposing factor, in cirrhosis of the liver in man. D.

Ætiology and Treatment of Lupus Erythematosus.—Macleod (*Practitioner*, Jan., 1908) reviews our knowledge of this disease about which so much has been written since Cazenave first described and named it in 1851. The most generally accepted explanation of its causation attributes it to the action of some local irritant or to the presence of some toxin either generated *in loco* or reaching the skin from some distant focus of disease, and attacking that part of the skin where from anatomical reasons the circulation is naturally weak. The French school of dermatologists, following Boeck of Christiania, believe that this toxin is tubercular, and have classified the disease as a "toxi-tuberculide." There are strong reasons against this teaching, and the evidence in support of it is by no means conclusive. Histologically the lesions differ markedly from those of tuberculosis, and every effort to demonstrate the presence of the tubercle bacillus in the lesions has failed. Attempts to produce the disease by the injection of tubercular toxin have likewise failed, and in several fatal cases careful postmortem examination has failed to detect any evidence of tubercular foci elsewhere. Macleod draws attention to the relation which exists between lupus erythematosus and various circulatory disturbances, such as chilblains and Raynaud's disease, on the one hand, and the toxic erythema of the type of erythema multiforme on the other. Macleod then suggests that lupus erythematosus is not a specific disease, but one which may be brought about by a number of causes in a predisposed individual. It is conceivable that the same toxin acting under different circumstances might produce the lesions of both lupus erythematosus and erythema multiforme. With regard to the treatment by radiotherapy, Macleod has found the Finsen-Reyn lamp much more efficacious than either the X-rays or high frequency. In using this treatment he follows the procedure suggested by Norman Walker, and exposes the skin at a distance of about ten inches from the lamp for half an hour every second day without employing a compressor. K.

Rheumatic Hyperpyrexia in a Child of Six.—Lock (*Brit. Journ. of Children's Diseases*, December, 1907) believes that this is the first recorded case of this complication of rheumatic fever in so young a child. About a year ago the child had an attack of chorea, which, however, got quite well, but left her with a rough systolic murmur which was audible at the apex beat. In September last she had an attack of acute pneumonia, which terminated by crisis on the fifth day. Two days later she had a return of the chorea, followed in three days more by well marked symptoms of rheumatic fever. She was then given five grains of sodium salicylate in an alkaline mixture every four hours, but next day the temperature was higher and further joints were involved. The chorea still persisted, and the dose of the salicylate was doubled. On the following day the temperature rose to 105° F., and ten grains of the salicylate were administered every hour. In the evening of the same day the temperature had risen to 107° F., and an ice pack was ordered, but though the temperature fell two degrees the cold was not well borne, and cyanosis and embarrassment of respiration followed. On the following morning the temperature rose to 108° F., and an hour later to 110° F., when the child died suddenly. The temperatures were taken in the rectum by a trained nurse, and verified by Mr. Lock. During the progress of the case there did not appear to be any fresh development of endo- or peri-carditis, and the swelling of the joints was not very marked. The pulse, though feeble, was never greatly hurried, but the respirations were very frequent and noisily panting in character. The most marked feature was the complete suppression of sweating. There was a plentiful crop of sudamina vesicles from former sweats, but the skin was quite dry and pungently hot throughout.

K.

Calcium Salts in Functional Albuminuria.—Wroughton (*R.A.M.C. Journ.*, January, 1908) records the case of a soldier who was admitted to hospital passing a small quantity of urine containing a considerable quantity of albumin. The patient was kept in bed for several days, and though the quantity of urine gradually increased there was no diminution in the amount of albumin. The patient presented no signs of nephritis, and the urine was quite clear and contained no tube casts. The patient, after four days in hospital, was put on five-grain doses of calcium chloride three times a day. The next day there was a large increase in the urinary water, and a considerable diminution in the quantity of albumin. Two days later the albumin had completely disappeared. This case would appear to corroborate the contention of Wright and Ross (*Lancet*, October 21st, 1905) that the effect of the administration of calcium salts may aid in the differentiation between functional and organic albuminuria. K.

Relationship Between Avian and Human Tuberculosis.—Shattock and others contribute an article on this subject to the *Lancet* for November 23rd, 1907. As a result of their experiments they have come to the following conclusions:—(1) The human tubercle bacillus is pathogenic to the pigeon in a very limited degree only. It sets up no disease of the intestine or of the abdominal viscera when introduced with food into the alimentary canal, and sets up a local, or local and glandular infection only, when injected into the muscles or subcutaneous tissue. (2) The avian tubercle bacillus, as tested from various kinds of birds, is pathogenic to the guinea-pig in a very limited degree. (3) The human bacillus is not convertible into the avian by inoculation into the bird—*i.e.*, the bacilli are not identical. (4) They maintain that, though either bacillus will exhaust the opsonin from tuberculous serum, this is no proof of their identity, as amongst other things the opsonin may be extracted from tuberculous serum by saturation with a thick suspension of melanin. M.

Empyema of the Antrum of Highmore.—Swirschkowsky reports the results of investigations made in 100 cases of empyema of the antrum of Highmore (*Russ. Med. Rundschau.*, Heft. 10, 1907), and formulates them as follows:—(1) Purulent inflammation of the antrum may be set up by a large number of micro-organisms. (2) Empyema is very often primarily due to a pathological condition of the teeth, and in consequence for diagnostic purposes a careful examination of the teeth is essential. (3) The so-called classical symptoms of an empyema, though present in simple cases, are seldom to be found in complicated ones. (4) In diagnosis the greatest weight is to be placed on the finding of a drop of pus under the middle turbinal bone. This is of more value than transillumination, although this last-named method of examination should also be employed. (5) Aspiration is only to be used as a diagnostic aid when all other means have failed. (6) Opening of the antrum is best carried out through the alveolar process, the second set of election being through the socket of the second molar tooth. (7) In carrying out operations for radical cure, the technique of Caldwell is to be chiefly recommended. M.

Treatment of Scarlatina by Rectal Injections of Moser's Serum.—Slatogocour (*Russ. Med. Rundschau.*, Heft. XI., 1907), finding that subcutaneous injections of serum for scarlatina were unpleasant and painful to the patient, has been experimenting with the serum to ascertain whether its beneficial effects were retained when it is given per rectum, and has come to the following conclusions:—(1) The value of the serum is just as great when given per rectum as when injected subcutaneously. (2) The dose required should be the same as when given subcutaneously—that is, from 200 to 300 c.c. (3) Complications are much rarer when the rectal method is practised, and especially the local irritation and swelling of the skin is avoided. (4) The rectal method is specially suitable for children on account of the above-mentioned advantages.

M.

Reflexes in Scarlet Fever.—Rolleston has made a systematic study of certain reflexes in 175 cases of scarlet fever, and has arrived at the following interesting conclusions (*Quarterly Journal of Medicine*, January, 1908):—(1) In many case of scarlet fever the normal plantar response of flexion is temporarily replaced by extension. (2) The severer the case and the younger the patient the more likely is this change to occur, and as a rule the severer the case the longer the duration of this phenomenon. (3) In a few cases all forms of plantar response are abolished. (4) In a large number of cases, whatever the types of response first obtained, there was an interval of varying duration, in which the plantar reflexes were absent. In some cases there was complete absence of this reflex, the muscles of the hip normally concerned in this response being as inactive as those of the foot. In others the hip reaction was brisk, while the muscles of the foot failed to respond. (5) The epigastric and abdominal reflexes are also affected, and the more severe the attacks the greater is the liability of their being affected. They are, however, less frequently affected than the plantar reflexes. (6) The cremasteric response is the briskest reflex of early youth, and is the least likely of all reflexes to be abolished. (7) The knee-jerks were found to be absent in three cases only, all of which were severe. (8) Knee joints attacked at the period of the endo-carditis showed more derangement of their reflexes than when afflicted during other complications of scarlet fever. M.

MEDICAL NEWS IN BRIEF.

Catholic University School of Medicine, Dublin.—Annual Dinner.

On Saturday evening the seventh annual dinner of the Past and Present Students of the Catholic University School of Medicine was given in the Dolphin Hotel. Professor Coffey presided. The dinner was very largely attended, and afterwards various awards were distributed to the students. Dr. Cox then proposed the toast of "The Medical School," to which Professor Coffey replied. In the course of his speech Professor Coffey said, referring to Irish University Education, that the outlook was now more hopeful. The Minister who had taken up this question had taken it up when disheartening circumstances might have excused his interference in it. No one would more readily recognise than they would the courage with which Mr. Birrell faced the problem, and they believed he would do his best to settle this scandal to the government of the country. As to the form of settlement, they had no definite knowledge, but he thought they might say that unless the settlement was to be academic, free, and generous, trusting the people, providing the opportunities which will enable the intellect of Ireland without sacrifice of principle to derive the highest benefits from education in Ireland; to raise the respect for Irish intellect among the civilised peoples of Europe—unless it was possible under the scheme that that should be brought home to the people, he thought he might say that the Catholics of Ireland would not be satisfied with the Bill. Again, in the settlement of the question, unless Mr. Birrell approached it in that generous spirit which would enable him to put himself in the place of the Irish Catholic, and recognise that there was no difference in sentiment or principle between the views of the Irish priest and the Irish layman, the Bill would not secure the support of the Irish people. Having expressed the belief that an educational settlement in the form of the Queen's College system would not give satisfaction, the Chairman concluded by saying that whether a settlement of the University system came or not, the work of their school would go on guided by the same principles, and be carried on with the same enthusiasm as that which had brought it to its present success. (Applause.) Dr. J. J. Fitzgerald (Cork), Dr. O'Farrell, and Mr. Barniville responded. Amongst the remaining toasts were "The Catholic College and Schools," proposed by Dr. A. J. Smith, and "The Guests," proposed by Mr. McArdle, F.R.C.S.

An International Congress of Ophthalmology.

The following gentlemen have constituted themselves into a Committee of Organisation for the XI. International Ophthalmological Congress, which meets at Naples in the spring of 1909:—President, Professor Angelucci; members, Professors Addario, Albertotti, Alessandro, Bajardi, Baquis, Bardelli, Basso, Bietti, Bocchi, Bossalino, Ceraso, Cirincione, de Berardinis, de Lieto Vollaro, Desogus, Falchi, Fortunati, Francaviglia, Frugiuele, Gallenga, Gatti, Gaudenzi, Gonella, Guaita, Lodato, Manfredi, Mazza, Monesi, Orlandini, Ovio, Parisotti, Pes, Petella, Puccioni, Rava, Reymond, Roselli, Santucci, Sbordone, Scalinci, Scellingo, Scimemi, Simi, Sgrosso, Tartuferi, Trombetta, and Valenti.

Following an old-established custom, and as some slight appreciation of their merit, they have conferred the honorary presidency on Professor Marc Dufour, president effective of the Congress of Lucerne, and the honorary vice-presidency on Dr. Landolt, member of the Organising Committee of that Congress.

From the programme elaborated by the preceding Congress, and unanimously adopted by the members thereof, they have compiled the regulations for the XI. International Meeting, a copy of which may be had on application to the English corresponding members. As soon as the final preparations for the Congress are made all other necessary notices and circulars, also particulars with regard to the journey, will be sent to inquirers, and the means by which it is hoped to render pleasant the short stay of the members of the Congress among us.

Intending visitors should inform the English corresponding member (Mr. Walter Jessop, 73, Harley Street, W.) of their desire to be present at the Congress.

Study of Tropic Disease.

At a gathering of Liverpool medical men on Saturday last, Sir Alfred Jones said the work accomplished by the Liverpool School of Tropical Medicine had set the world studying that subject. Liverpool had spent £80,000 in that investment, and there had been no better investment in the world, for it had saved thousands of people, and had brought the death rate in Africa down from 30 per cent. to 2 per cent. That was marvellous, and it would be more marvellous in future. It had enabled Europeans to live in Africa in safety, and enabled that country to get a better class of Europeans. The school was now engaged in investigating the "sleeping sickness." Unless they could check that disease there would soon be no population in Africa.

The Bristol Royal Infirmary Training School for Nurses.

The Committee of the Bristol Royal Infirmary have arranged to establish a preliminary training school for their nurses. Suitable premises have been secured for the purpose, which will be placed under the control of a sister, who will instruct candidates for admission to the nursing staff of the Bristol Royal Infirmary in the various matters pertaining to the profession prior to their being received into the wards. The curriculum is to be a very comprehensive one, and the time spent in this training school should prove of very great advantage to the probationers. The Bristol Royal Infirmary was one of the first three provincial hospitals started about 1735, and the authorities are again showing their progressive spirit by making this the first residential preliminary training school for nurses out of London. Indeed, there are only two such schools attached to London hospitals, the original one at the London Hospital and a more recent one at Guy's Hospital. The Bristol Royal Infirmary is to be congratulated on the step which has been taken.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

The quarterly examinations of the above Board, held in Edinburgh, were concluded on the 24th inst., with the following results:—

First Examination Five Years' Course.—Of 36 candidates entered, the following 18 passed the examination:—Michael Joseph Ahern, Probhat Chandra Mukherji, Nripendra Nath Chandra, Anath Nath Palit, William J. M. White, Edward E. W. Shiels, Walter S. Durward, Mrs. Dwarkabai Kamalakar, John N. N. Atkinson, Solomon D. Bridge, Singcha Hoashoo, Krishnarao G. Dhairyawan, Chandiprasad Trivedi, Marcel F. A. L'Hoste, Bhola Nath, Kaithail Koshi Jocab, Charles L. W. Fleming, and Lionel L. Coghlan, and 6 passed in Physics, 2 in Biology, and 1 in Chemistry.

Second Examination, Four Years' Course.—Mr. William Alexander Irwin passed the examination.

Second Examination, Five Years' Course.—Of 27 candidates entered, the following 11 passed the examination:—William Browne (with distinction), Maurice C. Anderson, E. R. Jones, Bikramajit Sahni, Cesar J. Lacayo, Kathleen Reed, Howard V. A. Gatchell, James Blackburn, Charles G. Timms, Chandiprasad Trivedi (with distinction), and Bhola Nath, and 1 passed in Physiology.

Third Examination Five Years' Course.—Of 35 candidates entered, the following 18 passed the examination:—William J. Cogan, Robert W. Pickup, Charles W. Gee, Hugh Millar, Cornelius O'Herlihy, Syed Abdul Karim, Harold Gordon Chouler, Robert Massie, Patrick Reid, Llewellyn E. Davies, MacWilliams Henry, Thomas B. McKendrick, John P. Synnott, Harold H. Field-Martell, Krishnarao G. Dhairyawan, William R. Griffith, and Sidney Sharples, and 3 passed in Materia Medica.

Final Examination.—Of 76 candidates entered, the following 26 passed the examination and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. and S.G.:—Robert Dick Orok, John H. C. Hicks, Charles A. Page, Meade L. Ford, Matthew H. Fleming, William C. Doughty, Edmund C. Kinkead, Ethel Adelaide Orchard, Mathew E. Grimshaw, William F. McKenna, Framroz Maneckji Vajifdar, Herbert W. Kerrigan, John Macdonald, Clement H. Heppenstall, Mundkur Shiva Rau, William S. Scheck, William W. McKinley, David Welsh, Alexander H. M. Maxwell, Satischandra Das, Caroline L. Kohlhoff, Zerk D. Lotter, Walter H. Wijenayake, Joseph L. Pinto, Sakharam R. Bhagwat, and George Lindsay Irwin, and 9 passed in Medicine and Therapeutics, 7 in Surgery and Surgical Anatomy, 15 in Midwifery, and 13 in Medical Jurisprudence.

Society of Apothecaries of London.

The following candidates having passed the necessary examinations, have been granted the L.S.A. Diploma of the Society, entitling them to practise Medicine, Surgery, and Midwifery:—A. R. Hardy and W. P. Pinder.

H.M. the King has sent a present of old linen to the Chelsea Hospital for Women.

NOTICES TO CORRESPONDENTS, &c.

☞ **CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. Half Page, 13 insertions, at 35s.; 26 at 32s.; 52 at 30s. Quarter Page, 13, at 18s.; 26 at 16s.; 52 at 15s. Eighth Page, 13, at 9s.; 26 at 8s.; 52 at 7s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

AN ANCIENT QUACK.

THE medical libel case, which has set us all thinking about patent medicines, would suggest a pilgrimage to the tomb of Lionel Lockyer, the famous empiric of Charles II.'s time, whose epitaph in St. Saviour's, Southwark, boasts that—

> This verse is lost—his Pill embalms him safe
> To future times without an epitaph.

A pamphlet, issued in 1670, advertises these "Pilulæ Radiis Solis Extractæ," as if they were any modern specific. Seventy-four cases are given, including ingenuously the man who thought ill of them after one box—"All such may keep their money and their diseases, too!"—and the man who "was left incurable, but was cured of a Regiment of diseases, and only by these pills." It is rather sad to see that such enterprise ended on one occasion in the White Lion prison; but the quack was no more loved by the authorities then than now.—*Daily Chronicle.*

LUPUS.—We believe we are correct in ascribing the plan to Professor Senator, of Berlin. He uses gelatine as the only "drug" in the treatment of gastric ulcer. His formula is:—

White Gelatine	50 grammes.
Sugar and Oil of Fennel...	āā q.s.
Water	450 grammes.

A tablespoonful every three hours or more frequently.

VITAL STATISTICS.

LONGEVITY IN EUROPE.—Longevity in Europe, says the American "Medical Record," is distributed as follows:—

Germany, with a population of 55,000,000, counts only 78 centenarians; France has 313 centenarians in 40,000,000 inhabitants; England, 146 in 45,000,000; Scotland, 46 in 4,000,000; Spain, 410 in 18,000,000; Norway, 23 in 3,000,000: Switzerland, 1 in 3,300,000; Denmark, 2 in 2,465,000; Belgium, 5 in 6,670,000; Sweden, 10 in 5,300,000. In the Balkan States the proportion of centenarians is considerable: Servia counts 573 in 2,625,000 inhabitants; Roumania, 1,084 in about 6,000,000; Bulgaria, with 3,300,000 inhabitants, has 3,883 centenarians. It will be noted that Bulgaria has the greatest number of centenarians of all the countries in the world. It is stated that there is about one centenarian to every hundred inhabitants. In 1892 350 centenarians died in Bulgaria.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 29TH.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20, Hanover Square, W.).—5.30 p.m.: Adjourned Discussion on Dr. Edgecombe's paper on Blood Pressure in Spa Practice (introduced by Dr. F. Fox). Mr. T. Hawksley: Exhibition of Blood Pressure Instruments.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m.: Mr. P. J. Freyer: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. W. Langdon Brown: Some Intestinal Intoxications.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Cliniques: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

GREAT NORTHERN CENTRAL HOSPITAL (Holloway Road, N.).—2.30 p.m.: Surgical In-patients (Mr. Stabb); Medical Out-patients (Dr. Horder); Gynæcological (Dr. Lockyer); Skin (Dr. Whitfield); Teeth (Mr. Baly); Operations (Mr. Stabb).

THURSDAY, JANUARY 30TH.

ROYAL SOCIETY OF MEDICINE (NEUROLOGICAL SECTION) (20, Hanover Square, W.).—8 p.m.: Cases. 8.30 p.m.: Discussion on "Tics."

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 p.m.: Card Cases. 8.30 p.m.: Mr. S. Snell: (1) Carcinoma of Orbit; (2) Colobroma of Iris in each Eye occurring in Five Generations. Mr. S. Mayou: Microphthalmia resembling Glioma, with Lenticonus and Hypertrophy of the Ciliary Body. Mr. L. Paton: Optic Neuritis in Cerebral Tumours. Dr. A. J. G. Barker: A Case of Suppurative Tenonitis.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. L. Williams: The Bogey of Albuminuria.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Lecture-Demonstration:—Dr. A. J. Whiting: Cases of Aneurysm of the Thoracic Aorta (at the Mount Vernon Hospital Out-patient Department, 7, Fitzroy Square, W.).

GREAT NORTHERN CENTRAL HOSPITAL (Holloway Road, N.).—2.30 p.m.: Medical In-patients (Dr. Morison).

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Lecture:—Dr. M. Dockrell: Syphilis: History and Primary Invasion (Constitutional and Local). Eruptions, Erythematous (I., Macular; and II., Maculo-Papular).

FRIDAY, JANUARY 31ST.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m.: Mr. S. Stephenson: Clinique. (Eye.)

GREAT NORTHERN CENTRAL HOSPITAL (Holloway Road, N.).—3.30 p.m.: Lecture:—Dr. C. Lockyer: Cancer of the Womb.

Appointments.

BURY, REGINALD FREDERICK, M.R.C.S., L.R.C.P.Lond., Honorary Surgeon to the Warneford Hospital, Leamington Spa.

GLOVER, J. A., M.D.Cantab., L.P.H., Deputy Medical Officer of Health to the Islington Borough Council.

HULBERT, J. G., Major, I.M.S., M.B., B.C.Cantab., Clinical Assistant to the Samaritan Free Hospital for Women.

MACMILLAN, EVAN, M.B., M.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Strathmiglo District of the county of Fife.

MANNERS, W. F., M.R.C.S.Eng., Clinical Assistant to the Samaritan Free Hospital for Women.

PURNELL, R., M.D.St. And., M.R.C.S., L.S.A., J.P., Member of the Visiting Committee for Shepton Mallet and Bristol Prisons.

SHIRVELL, EDGAR A., M.R.C.S., L.R.C.P.Lond., Resident Medical Officer at the Royal Albert Hospital, Devonport.

SMITH, G. F. DARWALL, B.M., B.Ch.Oxon., F.R.C.S.Eng., Surgeon to Out-patients at the Samaritan Free Hospital for Women.

STUART, FREDERICK, M.B., B.S.Durh., Clinical Assistant to the Samaritan Free Hospital for Women.

SUGDEN, W. A., L.S.A., Clinical Assistant to the Samaritan Free Hospital for Women.

Vacancies.

County Borough of Croydon.—Female Assistant to the Medical Officer of Health. Salary, £250 per annum. Applications to F. C. Lloyd, Town Clerk, Town Hall, Croydon.

Lurgan Union (Ireland).—Resident Medical Officer. Salary, £80 per annum, with apartments, laundry, and first-class rations. Applications to James Calvert, Clerk of Union, Workhouse, Lurgan. (See Advert.)

Leeds Tuberculosis Association.—Resident Medical Officer for the Sanatorium at Gateforth, near Selby. Salary, £100 per annum, with board, lodging, and washing. Applications to Chas. H. Sedgwick, Secretary, 37, Great George Street, Leeds.

County Borough of Salford.—Fever Hospital.—Assistant Medical Officer at the Ladywell Sanatorium, Salford. Salary, £150 per annum, with apartments and board. Applications to L. C. Evans, Town Clerk, Town Hall, Salford.

Borough of Bootle.—Hospital for Infectious Diseases.—Resident Medical Officer. Salary, £100 per annum, with board, washing, and apartments at the Hospital. Applications to the Chairman of the Health Committee, Town Hall, Bootle.

Northampton County Asylum.—Junior Assistant Medical Officer. Salary, £150 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent, Berry Wood, Northampton.

Cambridgeshire, etc., Asylum.—Second Assistant Medical Officer. Salary, £120 per annum, with board, lodging, and attendance in the Asylum. Applications to T. Musgrave Francis, Clerk to the Visitors.

County Borough of Great Yarmouth.—Assistant Medical Officer of Health. Salary, £200 per annum. Applications to W. Edgar Stephens, Town Clerk, Town Hall, Great Yarmouth.

Births.

BISS.—On Jan. 24th, at 75, Prince of Wales' Mansions, S.W., to Dr. and Mrs. Hubert Biss—a son.

JACKSON.—On Jan. 22nd, at Woodhouse, Bakewell, the wife of R. Houlton Jackson, M.R.C.S., L.R.C.P., of a daughter.

BARBER.—On Jan. 24th, at 45, Friar-gate, Derby, the wife of Hugh Barber, M.D., of a daughter.

Marriages.

ADAMS—SMITH.—On Jan. 20th, at St. Michael's Church, Oxford, Philip E. H. Adams, F.R.C.S., of Oxford, son of Dr. G. D'Arcy Adams, of London, to Marjorie, second daughter of Rev. A. C. Smith, M.A., of Banbury Road, Oxford.

Deaths.

ANDERSON.—On Jan. 25th, suddenly, Sir Thomas McCall Anderson, M.D.Glasg., F.F.P.S., Hon. Phys. to H.M. the King in Scotland, Regius Professor of Medicine, University of Glasgow.

BIRCH.—On Jan. 24th, at Newbury, Robert Birch, M.R.C.S., L.R.C.P., L.S.A., aged 57 years.

COVER WITH COTTON WOOL

THE DENVER CHEMICAL MFG. CO.
LONDON.

Cyllin Inhalator

By Appointment to H.M. the King

Cyllin Inhalant

as given off by the Cyllin Inhalator is most beneficial in all diseases of bacterial origin in the mucous lining of the throat, nose, and ears. It renders valuable assistance in cases of **Colds and Nasal, Pharyngeal, and Bronchial Catarrhs,** by killing in each case the causal micro-organism, thus cutting short the affection.

Cyllin is also put up as a syrup, and in capsule form (Palatinoids) for stomachic and intestinal antisepsis.

See pamphlet entitled "Standard Chemical Disinfectants." Copies, together with working Samples, sent gratis and post paid on applying to

Jeyes' Sanitary Compounds Company, Ltd.,
64 Cannon Street, London, E.C.

SCHERING'S

Beta-Eucain Lactate

The Local Anæsthetic par excellence.

Possesses all the advantages of Beta-Eucain Hydrochlor. over Cocain, but in addition is readily soluble up to 20 p.c. Can be sterilized by boiling. Toxic effects reduced to a minimum.

SCHERING'S

Urotropin

FABRIK-MARKE TRADE-MARK

Best known and most effective Urinary Antiseptic.

Highly recommended in all Diseases of the Urinary Passage, CYSTITIS, PYELITIS, PYELONEPHRITIS, &c.

"A distinct advance on Easton's Syrup."

—The Lancet.

Bynin Amara

'BYNIN' AMARA is an analogue of Easton's Syrup, in which the sugar is replaced by an active Malt Extract. This affords a far better vehicle than syrup, as it is actively digestive and nutritious, and there is not the likelihood of the sugar crystallizing out, and carrying down in the crystal the alkaloid principle.

As a digestive tonic, therefore, 'BYNIN' AMARA is not only safer to take than Easton's Syrup, but is of greater value both in aiding and strengthening the powers of assimilation.

It has been found very effective in neuralgia and similar nerve troubles.

COMPOSITION.

Quinine Phosphate	1½ grains.
Iron Phosphate	2 ,,
Nux Vomica Alkaloids equal to Strychnine	$\frac{1}{16}$,,
'Bynin, Liquid Malt	1 ounce.

DOSE FOR ADULTS—One dessert to one table-spoonful, suitably diluted.

A Sample Bottle will be sent free to Medical Men, on request.

Valentine's Meat-Juice

Whenever the **Stomach,** from any cause, **rejects food** or medicine, **Valentine's Meat-Juice** can be relied on to be retained and **to Nourish and Sustain when other forms of food fail.**

In low forms of **Pneumonia** and **Exhaustion,** in the **General Debility** with **Impaired Digestion** of **Phthisis,** and in the **Depressing Prostration** following **Influenza,** it is recommended by practitioners throughout the world as invaluable in their treatment.

Pneumonia, Phthisis and Influenza.

Frank Van Fleet, M. D., *Professor Diseases of the Eye, Post-Graduate Medical School and Hospital, New York:* "I was unfortunate enough to contract double Pneumonia last winter, which was followed by double Pleurisy and Empyema. During several weeks of unconsciousness I was nourished (after milk had begun to disagree with me) with Valentine's Meat-Juice exclusively."

Prof. Dr. M. Litten, *Lecturer on Internal Medicine, University of Berlin, and Director of the City Hospital, Berlin, Germany:* "I have employed Valentine's Meat-Juice with patients suffering from Tuberculosis, and observed excellent results from its use. I have also used it with good results in the treatment of patients with Anæmia, as well as those convalescent from acute diseases."

R. B. Watson, M. D., *Surgeon Pennsylvania Co. and Lockhaven Hospital, Lockhaven, Pa.:* "The results obtained from the use of Valentine's Meat-Juice establish all that is claimed for it. In a case of Phthisis it alone kept the patient alive for weeks, as it was the only nourishment she was able to take."

J. W. Dalrymple, M. D., *Medical Director Riverview Sanatorium, New York:* "It is with pleasure that I add my testimonial to the great value of Valentine's Meat-Juice in my hands during the recent epidemics of Influenza in this city, sustaining, as it did, the vital powers of the patients beyond the crisis and through convalescence, without their experiencing any degree of prostration."

VALENTINE'S
TRADE MARK
PREPARATION
NUTRIO PERME
MEAT JUICE.
The result of an Original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition (most important to life) are obtained in a state ready for immediate absorption.
Directions.—Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or moderately warm water. The Use of Hot Water changes the character of the preparation.

Physicians are invited to send for brochures containing clinical reports.

For Sale by European and American Chemists and Druggists.

VOL. CXXXVI. WEDNESDAY, FEB. 5, 1908. No. 6.

NOTES AND COMMENTS.

A Regrettable Error.

WE feel that we owe, and we hereby unreservedly tender, an apology to the *Lancet* and to some of our readers. In our comments last week on the libel case which our contemporary fought so fearlessly, we were made to say in the first line, "We need hardly say that the *Lancet* has *no* sympathetic condolences in the issue of the libel action brought against it by Mr. A. Q. Tucker." What was actually written was "*our* sympathetic condolences," and the proof was so passed for press. Owing to an accident to the type, the sentence had to be set up again at the last moment, and the word "no" was substituted for "our" without reference to ourselves. Unfortunately, a number of copies containing this almost grotesque error were sent out before it was discovered, but immediately we recognised it the issue was stopped, and the whole journal reprinted. Mistakes of course will occur in the best regulated families, but this was a particularly unfortunate one, and the sole consolation we have is that the misprinted copies only reached medical men, who must have observed that there was something wrong. The *Lancet* has our *most* sympathetic condolences on the result of the action, and we trust that the rest of our remarks last week made it sufficiently plain that we have nothing but admiration for the public spirit that actuated it all through the Tucker case.

Free Studentships in Midwifery.

THE modern midwife finds herself, thanks to her enthusiastic but injudicious supporters, in the anomalous position of being "neither fish, flesh, fowl, nor tasty kipper." She has been pitch-forked into the community under a farcical system of "inspection," the inspector often living twenty or thirty miles away from those whom he is supposed to have under his eye, and, as a salve to medical opinion, she is enjoined to call in a medical practitioner when she gets into a tight corner, the medical man giving his services for the love of humanity and in the teeth of his convictions. The most shocking cases of ignorance and neglect come before the Central Midwives Board, and probably many a mother's life is lost through sheer ignorance. Far from recognising that midwifery is a skilled art involving an intimate knowledge of medicine and surgery and one that should only be practised by medical men or trained midwives under the immediate personal supervision of medical men, the supporters of the present system seem bent on raising the midwife, not only to the point of being an independent practitioner, but of an independent authority on her art. At Cardiff, last week, a sub-committee of the Technical Instruction Committee decided to request the medical officer to report on the qualifications of any midwife who, in his opinion, would be capable of training pupils! It appears that the Committee is so "flush" that they wish to found twelve free studentships in midwifery, although a medical member informed them that there are already a sufficient number practising in Cardiff, "and 50 per cent too many." However, in the blessed name of education, the studentships are to be founded, and the holders, we gather, are to be trained by the present ladies in their practice. If such training is to be accepted as qualifying them to be placed on the *Register*, we can only say that we are excessively sorry for the poor mothers of Cardiff.

Free School Certificates.

WE should, we hope, not be suspected of any want of sympathy with elementary education if we express the opinion that the compulsory character of the Act of 1871 is leading the community to many strange positions which it little dreamed of when the Bill was before it. The provision of meals necessarily follows from forced attendance at school, as it is obvious that it is mere folly to attempt to teach hungry children. Equally obvious is it that the State could not indefinitely shut its eyes to the physical defects of children whom it drove to seek knowledge at its school, but who could not acquire it, because of physical disability. Medical inspection has been duly inaugurated, and to ourselves it seems logically to follow that if the system be eventually popular and successful, the State will sooner or later be forced to provide not only medical inspection, but medical treatment for those suffering from defects which idle or careless parents neglect in spite of due warning. Then, too, there is at present the pressing difficulty of school certificates for children absent through sickness. It certainly is not the duty of hospital officials to give such certificates, and when a child is absent from school and not under a private practitioner, no one else can. The attendance officer is in the dilemma of being bamboozled by crafty parents on the one hand, and bringing into the police-court those with a genuine reason for the child's absence on the other. A batch of summonses came last week before Mr. Paul Taylor, who lately earned the eternal gratitude of the medical student, and one woman pleaded that her child was ill, but that she was unable to pay a doctor for his certificate. Mr. Taylor opined that the parish doctor or some official ought to be paid out of the public funds to give such certificates free to the poor, and the attendance officer promised to bring the matter to the notice of the education authorities. There would be no difficulty of any kind if the education authorities would consent to pay a sufficient fee for such certificates. If the information is worth having it is worth paying for, and there is no need for salaried officials to be created *ad hoc*, when there are plenty of private practitioners to do the work. But doubtless, as in all other cases where medical service is required, educational bodies do not see why the certificates should not be given free.

Free Ambulance Lectures.

INDEED, the amount of freedom which is supposed to characterise medical service in every line of life would be ludicrous if it did not have its pathetic side. At the annual meeting of the Middlesborough and Cleveland Centre of the St. John's Ambulance Association last week, the local paper says that it was not "of a very inspiring character, and the report presented was not as encouraging as could be wished." It describes the good work that has been done by the students, but says that finances are not as flourishing as the supporters wish. It adds naïvely that the "prospects are not improved by the possibility of the medical men demanding fees for the instruction of classes." It is only in human nature that the supporters of an institution should become a little lukewarm when there is a prospect of being called upon to pay a little more, but we sincerely hope that the medical men will make the "possibility" of demanding a fee into an undeniable certainty. The work of the St. John's Ambulance Association is undoubtedly useful, but that is all the more reason why it should be paid for at an appropriate rate by those who devote their time, professional knowledge, and skill to its execution. Continuing its report, the newspaper says: "One noticeable feature of the meeting was the fact that it consisted entirely of employers or their representatives." We are left in no doubt, then, as to who the gentlemen are who support the Association's work, and who presumably think it worth while to encourage their employees to learn. It is hard to believe that employers, who are men of business, seriously expect medical men who live entirely by their own personal effort to give up their time for nothing in order to teach their employees a useful art. The medical men, at least, will find the lectures none the less appreciated if the lecturer receives his proper remuneration for his work.

Free Reports on Compensation Cases.

ANOTHER Northern journal, the *Manchester Dispatch*, is grumbling apparently because hospital surgical officers do not furnish free reports on accident compensation cases, and because "it is also alleged that claims for compensation are not too warmly espoused by hospital doctors, and that it is only reluctantly that they give evidence on behalf of sufferers." We admit freely the difficulty which the poor are placed in by being poor. The law is a luxury which society has decided to make as inaccessible to those who work for their daily bread as champagne suppers and trips to Monte Carlo are. It is a cruel grievance that the poor cannot enjoy the same access to the processes of justice as the rich do, but the fault is with society and not with the medical profession. The highest legal skill is not placed freely at the disposal of the poor, even in the case of murder trials, but the highest medical skill is available free for the most trivial ailment. Because medical men have, out of compassion, laid themselves out to serve the poor in time of sickness, it by no means necessarily follows that they should also give up their time and employ their skill to remedy the wrong which society inflicts on the poor in their temporal circumstances. The Government were asked, when the Workmen's Compensation Bill was before the House of Commons, to provide salaried medical practitioners to adjudicate on all claims made under the Act, and they refused. The workman was left to work out his own salvation, and if it is made sufficiently plain that medical men have not the time to spare to examine, report, and give evidence in compensation cases "on spec," it may be that a satisfactory solution will be provided. At present it seems to us that the only feasible plan is for the trades unions to employ their own doctors for their members who meet with accidents and whose claims are disputed. But the matter is not one for private medical charity.

LEADING ARTICLES.

FERGUSSON V. THE MALVERN COUNCIL.

LAST week an important case was settled in the King's Bench Division by a judge and jury. The action was brought by Dr. John Campbell Fergusson against the Malvern Urban District Council to recover damages under somewhat peculiar circumstances. The plaintiff owned a hydropathic establishment in Malvern. In May, 1905, an outbreak of enteric fever took place in this establishment, involving no less than fourteen persons, several of whom died. As the result of subsequent litigation Dr. Fergusson was called upon to pay £7,000 in compensation and damages on account of the infection incurred at his institution. He thereupon entered an action to recover damages from the Urban District Council, on the ground that the outbreak was caused by the pollution of the water supply by sewage under the control of the Council, which thereby became responsible. The drinking water came from the Tudor Well, and the jury, when asked the specific question by Mr. Justice Lawrence, found that the plaintiff had no property in the water flowing from that source into his tank. The point is of much technical importance, as an appeal against the subsequent verdict fixing responsibility on the Council may be based thereon. The plaintiff's allegation was that the drinking water at his establishment had been polluted by sewage negligently allowed by the Council to escape from their sewers. The defendants denied that they had negligently allowed sewage to escape from the sewer, and pleaded that even if such escape took place it was not the actual cause of the outbreak, which was rather due to the bad sanitary appointments of the hydro. They further said that in law the plaintiff had no cause for action, as he had no proprietary right in the water which was said to have been polluted by sewage, nor had he obtained any licence to take it. After a long and patient trial the jury found that the Council were guilty of negligence in permitting sewage to escape from their sewer, but that the plaintiff was not guilty of contributory negligence. They further found that the escape of sewage was the only cause of the outbreak, and that the state of the drainage of the house was not concerned, while the infection could not have been avoided by any reasonable care on the part of the plaintiff. Damages they assessed at £7,500. Although the responsibility of local authorities for polluting water has been established in various trials, there do not appear to be any cases in which responsibility has been fixed upon them for polluting a private supply of drinking water, as in the present instance. That is of course a different circumstance from the pollution of streams or watercourses, which, by the Public Health Act of 1875, local authorities are expressly forbidden to pollute with sewage. Indeed, the recognition of the absolute necessity of the preservation intact of our drinking water supplies lies at the root of any sound national system of public health administration. The work of the sanitarian, however, is far from complete in this direction. A vast deal of sewage is poured into our streams and rivers, and the metropolis of the kingdom, with its vast population, is for the most part supplied with water that has been grossly contaminated. The whole country, in short, is urgently in need of a new and stringent Act for the prevention of pollution of streams and rivers. The main difference between the United Kingdom and a country like India, that is ravaged by pestilences of various kinds, lies in the relative purity of the home drinking water supplies. Jamaica, formerly one of the most deadly of tropical stations, has now become a healthy island, with good water supplies. In advancing this general statement it should be added that a better system of sewage disposal is connected with improved drinking water supply. So far as the Malvern trial is concerned, it will be of inestimable value in attracting the attention of local authorities throughout the kingdom to a due sense of their responsibilities in the control of sewage. Should the Malvern decision be upset on appeal it is reassuring to note that the only ground of appeal is on an issue of proprietary right in a particular supply of water, and not the question of the responsibility of a local sanitary authority to keep its drains watertight.

THE DIMINISHING BIRTH-RATE.

The chief point about the national birth-rate is that it still diminishes, and the vexed questions raised by philosophers, sages, and moralists remain unsolved. The annual report of Sir William Dunbar, Registrar-General of Births, Marriages and Deaths, has been issued for the year 1906. In the years 1900-1902 the rate of fertility amongst married women in England and Wales was, with the exception of France, lower than that recorded in any European country. That this diminution is in some part due to the modern inclination of mothers to limit the production of offspring appears to be borne out by the official figures. While on the one hand the number of births decrease, there is no evidence that marriage is becoming unpopular. So far from that, the marriage-rate in 1906 was 15.6 per 1,000 of the population, a point that compares favourably with its predecessors for the past two decades. The exception occurred in the year 1899, when the rate was 16.5 per 1,000, and the years 1896 to 1902, when the matrimonial market appears to have been remarkably brisk. Compare with these figures the number of marriages in 1886, which was only 14.3, or that of 1893, when it was 14.7. The diminution of births, therefore, is clearly not due to fewer marriages. Of other explanations that have been advanced, one that has been repeatedly advanced is that marriage is being postponed to a later age. The tendency exists, it is true, but figures seem to show that it is nothing like so important a factor in the situation as its advocates would have us imagine. From the Registrar-General's figures we learn that in ten years there has been a rise of 0.44 per cent. in the age of bachelors marrying, and of 0.34 in the corresponding age of spinsters entering into the marriage state. Translated into terms of everyday life, these percentages simply mean that the average bridegroom going to the altar for the first time is five months older than he was ten years ago, and the average bride four months older. The mean age of brides who have not been married before is 25½, while that of bridegrooms under a similar condition is rather over 27. One remarkable fact is the steady decrease which has been going on for years past in re-marriages. This circumstance may perhaps be partly accounted for by the decline in the death-rate and the consequent longer duration of first marriages. As regards the central feature in the position disclosed by the Registrar-General, there can be little question as to the vital import to the nation of the diminishing birth-rate. In spite of the attention that has been bestowed upon this point by many competent observers during the past few years, it cannot be said that any satisfactory solution has hitherto been advanced. If the diminution in the increase of population be a sign of decadence, then we, in common with other civilised countries, have arrived at a stage of lessened collective prosperity. On the other hand, it might possibly be conjectured that mankind is acquiring a sounder view of the scientific aspects of his duties in the reproduction of his species. His sense of responsibility to his offspring may be undergoing some profound, if unrecognised, change whereby he is growing more cautious in the discharge of his marital relations. The morality of parents procreating children whom they are unable to bring up under decent conditions as to food, clothing, and education, is surely open to question. Yet it is the principle, differing only in degree, which has, in all probability, determined the decreased birth-rate which has for years past produced so remarkable a result among the middle classes of the United Kingdom. The whole subject is of a complex nature. It bristles with fallacies and involves a host of considerations, moral, social, physical, and economic, some of them of a most obscure and controversial kind. In view of the vital importance of the matter to the community, it is to be hoped that competent scientific authorities will take up its consideration in a calm and scientific spirit. In various ways the question is intimately concerned with that other great national problem, excessive infantile mortality. It may be that the diminishing number of births on the one hand will be more than amply compensated on the other by the better preservation of the young of our population who are now so ruthlessly sacrificed to the imperfections of their environment.

CURRENT TOPICS.

"Printers' Errors."

It is understandable that the average man should tear his hair and run the gamut of wild emotions when he finds his choicest copy "disfigured"—as he terms it—by fantastic printers' errors. Possibly if he were more closely acquainted with the inwardness of the situation, his soul would be moved to pity rather than to anger. The occupation of printers' readers, operators on linotype machines, and of compositors is conducted in quarters that are often crowded, noisy, malodorous, and ill-ventilated, and where the hours of labour are often necessarily prolonged by overtime. There is the additional risk of lead-poisoning from handling the type, an acquired condition that leads to anæmia and ill-health of a mild but chronic nature. Then, again, the glare of some modern types is extremely fatiguing and, we believe, injurious to the eyesight of all concerned. Under these circumstances of physical drawback it is a marvel that so comparatively few errors occur in the unceasing torrents of printed matter that daily flood the world. The printer is undoubtedly in many instances the scapegoat for bad handwriting or worse composition. We would suggest that a Royal Commission might possibly discover some method whereby the path of a future generation of printers might be made smoother, and the pillow of many an editor and journalist cleared of its crumpled rose leaves.

A Bath-room Tragedy.

THE Coroner for South-West London, Mr. Troutbeck, last week inquired into the circumstances attending the death of a late inmate of Chelsea Workhouse Infirmary. By an oversight of the bathman the deceased had been left alone in the bathroom for about two hours, an exposure which, in the opinion of the jury, accelerated death from "natural causes," There are several points worthy of attention arising from this inquest, which, by the way, took place some time after the death, and the body was actually exhumed. The Coroner, distrustful for some reason or other of the powers of the local medical practitioners, called in the services of his "expert" pathologist, Dr. Freyberger. His report was that the cause of death was heart failure, while the deceased was suffering from acute inflammation of the lungs, and acute relapse of chronic inflammation of the kidneys. In view of the history of the case he was further of opinion that the treatment in the bath-room would accelerate the man's death. Facts and inferences of this nature would surely have been attested to by medical practitioners of the district, who have discharged their duties with efficiency and credit from time immemorial. In summing up the Corner remarked :—"This man's death has been accelerated by an inexcusable mistake. The infirmary has been allowed to get into a state where there is carelessness and loose working on the part of many people, from the highest to the lowest. I hope that what has come out in evidence will be sufficient to cause a serious inquiry as to whether there can be a great amendment in the working of the infirmary." So strong an expression of opinion must clearly have been founded on previous experiences of the working of the institution. We are of opinion that the Local Government Board would do well to make a searching inquiry into the administration of the whole of the Metropolitan Poor-law Infirmaries.

The Trade in Tuberculous Meat.

THE potential cost of the bad butcher to the State by way of the disease he scatters broadcast is simply incalculable. It is impossible to say that the tubercle bacillus is effectually killed by any ordinary process of cooking, and it follows, therefore, that the flesh of tuberculous cattle, if used for the food of man, carries with it the active germs of infection. These propositions being granted, it remains for sanitary authorities to exercise to the utmost whatever powers they may possess to stamp out the trade in tuberculous meat. It is to be feared that in many districts the new gospel has not penetrated, and farmers and butchers place their pernicious wares on the market without fear of punishment. On the other hand, it is reassuring to find that vigorous steps are being taken to repress the traffic. Last week, for instance, the Mitcham Medical Officer of Health, Dr. Fegan, instituted a successful prosecution against a local butcher who had a badly diseased tuberculous cow in his possession. Previous offences were proved against the defendant, who was sent to prison without the option of a fine. As a matter of fact, public opinion has not yet been educated to the proper attitude on this important subject of the identity of bovine with human tuberculosis. Many educated persons are found ready to advocate in public the opposite theory, and the former difference of opinion amongst medical authorities on the point is still grasped at eagerly by those interested in maintaining the present order of things.

Teething Powders.

IT appears to be somewhat the fashion nowadays to make light of the warnings of the medical profession against patent and proprietary nostrums, and to announce off-hand that their motives are those of self-interest. If there be any directly selfish motives in the matter, the average man in the street would assign them with little difficulty to the newspapers and the patent medicine proprietors who reap so golden a harvest out of this questionable traffic. Take the one point of so-called teething powders. As a matter of fact, no such specific medicament exists, or can exist, in the nature of things as known to scientific medicine. Many of these nostrums contain morphia and many others calomel, and there need be little hesitation in agreeing to the general proposition that a great many children are killed every year by the use of "teething powders." As all medical men know, morphia is a peculiarly deadly drug when administered to infants and children. Why should an ignorant drug vendor be permitted to distribute his perilous morphia-laden wares wholesale when the practice is condemned utterly by medical science? The City of London Coroner was not far off the mark the other day when he remarked that if he had the power, he would make it a criminal offence to put morphia into teething powders. Another frequent source of danger in these catchpenny remedies is the slow conversion of a portion of the contained calomel into corrosive sublimate. To the presence of the latter irritant, rightly or wrongly, is attributed many of the convulsions in babies associated with the adminstration of popular teething powders.

The Origin of Cancer.

ANYTHING that may possibly throw any light on the origin or the cure of cancer deserves to be regarded seriously, for the true light may eventually come from the least expected quarter. At the same time, it may be admitted that there is hardly any malady around which has gathered from time to time a more plentiful crop of theories that have not withstood the tests of time and experience. The parasitic nature of cancer is a fascinating conception to many minds, and some of our most experienced scientific investigators have published observations that led to the hope of a solution of the problem of the etiology of this most baffling disease. A further contribution in a similar direction has been made by Dr. Ford Robertson, pathologist to the Scottish asylums. The rod-shaped bodies he describes in malignant growths are revealed on microscopic examination only after staining by a special method. Should these observations be confirmed, the door will be opened into a new area of investigation. Whatever the final solution may be, all believers in the progress of science will retain an unshaken conviction that the full knowledge of cancer will one day be delivered into the hands of man. Meanwhile, the day of complete illumination would be immeasurably hastened were the State to endow scientific research with ample funds, so that all theories of *primâ facie* value could be subjected to absolutely rigid and unbiassed investigation.

University Education in Ireland.

The announcement in the King's Speech that Parliament will this Session be asked to consider a measure "to extend and improve University education in Ireland" will be received with satisfaction by most of those who are interested in educational questions in Ireland. There are, of course, some who will be opposed to any change, but most people will agree that the present unrest is almost worse than any fixed system, however faulty. As no contradiction has appeared, we may presume that the Bill, when it appears, will be something on the lines recently laid down by the Provost of Trinity College. That is to say, Dublin University will be left untouched, and the Royal University will be re-constituted, and will consist of four colleges—the three existing Queen's Colleges and a new college to be established in Dublin. Whatever be the faults of the scheme—and doubtless many will be discovered—it at least has the advantage over previous schemes, that it will not arouse a fierce opposition. It provides for a development of existing institutions along the line of least resistance. If, consequent on the establishment of the new college, the present hostility of a large proportion of the population toward Trinity College and the Queen's Colleges may disappear, the gain to the cause of Irish education will be enormous. We hope that the low position of the Bill in the list of measures in the King's Speech does not mean that it is in danger of postponement to another session.

The Place of Public Health in Municipal Government.

Judging the matter from an entirely detached standpoint, one would think that there was nothing more important in municipal concerns than the health of the citizens. In consequence, one might conclude that there were few matters of greater moment in municipal management than the care of the public health, but we fear that this view does not commend itself to many of the members of our municipal boards. An instance, in itself quite unimportant, but well illustrating the attitude of the community toward public health questions, occurred the other day in one of the suburban townships of Dublin. A gentleman, elected for the first time to the Council, after a few days wrote to the papers complaining of the treatment given him by his colleagues. He had expected, he said, to be put on some of the important committees of the Council, but instead he found a place on one committee only, and that an unimportant one—the Public Health Committee. It is difficult to imagine any sentiment more completely unfitting a man for such a position as this gentleman holds, but we fear that he does not stand alone in his contempt for the most important asset of any community. In a few places a more enlightened spirit prevails, but in matters of public health we fear that Ireland still lags far behind the rest of the Kingdom.

PERSONAL.

Mr. Charters Symonds delivered the Lettsomian lecture of the Medical Society on February 3rd, on "Tuberculosis of the Kidney"; and on February 17th and March 2nd he will lecture on "Malignant Disease of the Cæcum."

Professor R. Tanner Hewlett has been appointed Milroy Lecturer for 1909 at the College of Physicians of London.

At the same College, Dr. J. A. Ormerod has been appointed to deliver the Harveian Oration on October 19th of this year.

Dr. William Carter, who, on his retirement, was entertained at dinner by his professional and other friends on January 18th, was presented with his portrait in oils on that occasion.

The Bradshaw Lecture will be given in November this year by Dr. William Pasteur.

A special meeting of the Sunderland Health Committee was held on January 28th, to meet Dr. Manby, inspector of the Local Government Board, who is making a systematic survey on behalf of the Local Government Board of the ports of the Kingdom.

Dr. Leonard Guthrie will deliver the FitzPatrick Lectures of the Royal College of Physicians of London.

Dr. T. S. Edwards, of Edinburgh, has been awarded the Murchison Scholarship, founded to perpetuate the memory of Dr. Charles Murchison, and awarded alternately by Edinburgh University and the Royal College of Physicians of London.

Professor William Osler, M.D., F.R.S., Regius Professor of Medicine at Oxford, and Dr. Arthur Latham, Physician to St. George's Hospital, have been chosen to fill vacancies on the council of the National Association for the Prevention of Consumption.

The following Fellows of the Royal College of Physicians of London have been elected members of the Council of that body:—Dr. E. E. Herman, Dr. D. W. Finlay, Dr. N. I. C. Tirard, and Dr. W. P. Herringham.

At the 25th annual dinner of the Sanitary Inspectors' Association, held on Saturday night at the Hotel Cecil, Sir James Crichton-Browne, the President, occupied the chair.

At the thirteenth annual dinner of the Mirfield and District Medical-Chirurgical Society, held at Batley Town Hall on January 20th, Dr. J. D. Doherty, of Batley, this year's President of the Society, occupied the chair.

The Somerset Education Committee have appointed Dr. Stevenson, of Walthamstow, as Medical Inspector for the county, at a salary of £500.

A CLINICAL LECTURE
ON
GENERAL SURGICAL TECHNIQUE.

By W. I. de COURCY WHEELER, M.D., F.R.C.S.I.,

Surgeon to Mercer's Hospital, Dublin.

GENTLEMEN,—In recent years surgeons have not thought it necessary to write or lecture extensively on the subject of general surgical technique, regarding it as a question already settled in principle, though varying in detail with individual workers. Yet I venture to think that, by adopting such an attitude, the profession may fall into the same error as Ambrose Paré in the year 1597, who claimed that he had so far perfected the art of chirurgery that there was nothing left for posterity "but a certain small hope to add some things."

To-day I intend to elaborate the principles and practices you have seen for some years adopted in this hospital, touching on many points, rather than labouring the various theories on the question of asepsis *versus* antisepsis, or to discuss in detail any of the matters bearing on surgical technique. Many volumes have been published on each of the subjects to which I intend to refer, and extensive details would be of no advantage to you, even if time permitted, in such a lecture as this. When you commence to operate you will be puzzled at first by the different pathways surgeons follow in order to gain the same end, and when you have imitated many methods which appear scientifically sound, you will gradually adopt a technique of your own, by following which the best results will be obtained. It is a mistake to adopt slavishly any single method of operating, for in the hands of one it will bring forth ideal results, but will bring discredit on the work of others. Whatever routine you follow, let it be based on scientific principles sufficiently weighty at least to satisfy your own mind, distinguishing such scientific principles from "fads" with which surgical literature abounds.

Asepsis and Antisepsis.—The indications for the use of antiseptics in modern surgery are becoming less, and if you have followed the various surgical cases to the theatre, you will have noticed that the use of them is conspicuous by its absence. Even in septic cases, such as compound fractures, the liberal use of normal saline solution has completely replaced the old reliance on antiseptics. Mechanical rather than chemical principles underlie the purification of the skin, surgical cleanliness being accomplished by thorough scrubbing of the hands with soap and running sterilised water, followed by the application of ether and alcohol. Neither of these latter are used as germicides, though alcohol when diluted has an undoubted antiseptic effect. This treatment of the skin is in keeping with true aseptic principles, the ether and alcohol acting mechanically by removing the fat and hardening and dehydrating the skin. Whatever preparation is preferred for the hands of the operator must be as rigorously carried out in the case of the skin of the patient, though in the latter it is well to dispense with the use of the nail-brush lest the skin be irritated and the healing of the wound delayed. It is absurd to lay down any definite time required for cleansing the hands; it depends entirely on the condition of the skin and the vigour with which each individual proceeds to wash.

The watery solution of bin-iodide of mercury has been replaced by an alcoholic solution, and with this the hands are often treated when the commercial alcohol is not available. Anyone who uses alcohol in the preparation of the hands gets a sense of cleanliness which no other chemical imparts. Other more complicated methods are also scientifically effective in the preparation of the hands; for example, Harrington's solution of alcohol, hydrochloric acid, and corrosive sublimate used for some months, but was abandoned owing to the injury done to the floor of our theatre when it was splashed, and to its irritating effect on the hands. It must not be supposed that antiseptics of an unirritating kind are in any way harmful to the uncut skin, but they can be dispensed with, and once the incision is made, it is hardly necessary for me to remind you that no antiseptic will kill pathogenic organisms in the tissues. Any inhibition which they produce is counterbalanced by a proportionate inhibition of the vitality of the leucocytes and of the karyokinesis which precedes cell division. "Antiseptic washing and douching can, therefore, only be occasionally justifiable when the chemical injury caused by it is more than counterbalanced by the infective material destroyed." For these reasons the instruments (after being sterilised dry in the steam steriliser with the dressings) are lifted out, wrapped in a towel, and arranged on a table covered with sheets for the operation. They are not allowed to stand in carbolic or other lotions lest the tissues should be impregnated with an irritant every time an instrument is used. Furthermore, it is a contradiction to keep polished sterile instruments in an antiseptic solution when the wound and the hands of the operator can be safely exposed to air infection. In a modern theatre air infection has been proved to be negligible; but lest an air infection be converted into a contact infection during a prolonged operation, the instruments can with advantage be washed occasionally in saline solution. It is scarcely necessary to say that dry polished instruments are less likely to become infected than the wounds, or the hands of the operator. The large majority of septic cases arise, not from air infection, but from either contact or implantation infection. By contact infection is meant, for all practical purposes, the use of unclean instruments or hands; implantation infection is usually brought about by the burying of improperly sterilised silk.

Ligatures.—The sterilisation of and the whole question of the use of ligatures requires careful attention, in order to avoid such dangers as implantation infection, stretching of scars causing ventral herniæ, and other untoward results to which I will presently refer.

The substances you have seen used are silk, catgut, aluminium bronze wire, silkworm gut, and Michel's skin clips.

In almost every abdominal case the buried sutures have been of fine silk, catgut being only used in cases where asepsis could not be assured or when pus was actually present. You will recollect a series of appendix cases where fine silk was used to ligature the stump, and throughout the operation, and in contrast to these you have an illustration of the treatment of fulminating appendicitis in a case last year in the female ward in which every buried suture was of catgut. In the male ward two patients side by side, one a nephrectomy for tubercular disease, and the other a case on whom nephrolithotomy was performed for the removal of several renal calculi, illustrate a class of cases where it is difficult to decide whether silk or catgut should be used. In the first case the kidney was the site of multiple abscesses, and though tubercular pus may, as a rule, be considered sterile, a mixed infection is often present, and in all cases the resistance of the tissues against unavoidable infection is much lessened. Here, then, was a case where the renal artery, vein, and ureter required ligature. Any failure in the catgut would result in hæmorrhage, while the use of silk followed by infection entailed a very prolonged convalescence, the closure of the wound being delayed until the silk was either removed or came away spontaneously. I used silk in this case with the result I have mentioned. In the nephrolithotomy case micro-organisms undoubtedly accompanied the formation of the stones; yet it was tempting in the absence of visible sepsis, after uniting the kidney with catgut (here silk is contra-indicated, lest it predispose to the formation of fresh calculi) to bring the muscles together with silk, and so to guard against lumbar hernia. Here, again, it would have been better had I used catgut throughout, as the silk became infected and gradually presented, and was pulled away. Both cases have left hospital quite well after a somewhat prolonged canvalescence.

Silk.—The great advantage in the routine use of silk, especially in uniting aponeuroses in abdominal cases, is the mechanical support which it gives as distinct from absorbable catgut. I have been fortunate enough never to have experienced ventral herniæ after a laparotomy, with the exception of a case on which the Talma-Morison operation was performed for the cure of hepatic ascites, but the nature of this operation prevents proper closure of the abdominal wound.

Kocher, referring to the question of ventral herniæ, asepsis and suturing, says:—"But we can go still further and say that those who cannot bring themselves to employ permanent sutures, and who rely on absorbable catgut for buried sutures, can never hope to obtain as firm a closure of a wound as can be got with a buried organic non-absorbable suture."

In some instances aluminium bronze wire may with advantage supplement buried silk or replace it. In a large ventral hernia, after a laparotomy performed elsewhere, this material was used to bring the widely separated margins of the linea alba together, and the radical cure of an inguinal hernia was accomplished by the use of the wire in a patient who has just left the hospital. One or two boilings of silk may not render it sterile unless it be extremely fine, so, wherever practicable, the preparation of silk should entail an immersion in ether for twelve hours, in alcohol for twelve hours, and afterwards boiled and stored in 1—1000 corrosive sublimate, a second boiling being given immediately prior to operation.

Catgut.—Even when catgut is sterilised by a reliable method, its durability and strength often remains in doubt. The time in which catgut of given strength will be absorbed in such various tissues as the peritoneum, intestines, muscles and aponeurotic structures, is still a matter of uncertainty. I demonstrated to you one of the fallacies of a continuous catgut suture in the case of a girl from whom I removed a large cartilaginous foreign body from the knee-joint. On the second day after operation, owing to the mysterious disappearance of a small drainage tube, I re-opened the wound lest it had slipped into the joint unobserved. Though this was found not to be so, the following observation was noted:—"The continuous catgut suture which was used to unite the capsule and synovial membrane was found to have become absorbed at about the middle, rendering the entire suture loose and useless."

Probably, the simplest and most satisfactory way to sterilise catgut is that which I have now on trial. The raw catgut is rolled on glass slides and immersed for eight days in a 1 per cent. solution of iodine. It can be removed and washed in a little sterilised water or saline solution immediately prior to use. The catgut may remain in the iodine for a couple of weeks, but after that it becomes unreliable, and so, to save waste, any surplus remaining after the eight days' immersion may be stored in alcohol. The solution is made by dissolving a little potassium iodide in water, adding some powdered iodine and filling up the vessel to make a 1 per cent. solution.

Gloves.—I need not detain you long on the subject of the use of gloves. Most surgeons use them in septic and aseptic cases; yet they are not a necessity, bacteriological investigation having shown that the hand becomes spontaneously germ free, if not constantly exposed to reinfection. Such a leader as Kocher is not wedded to them, and Stiles does not use them. I have seldom operated without gloves, and I believe, under the conditions we are compelled to work, they are a great prophylactic measure against infection. Some surgeons are more careful to use gloves between operations when examining and dressing infected cases than at the actual work in the theatre. Kocher goes so far as to say:—"If a doctor finds it impossible to avoid loading his hands with pathogenic organisms, then he must leave operative surgery to others; but we do not see why a doctor who wishes to operate should not put on gutta-percha gloves when he has to make a digital examination of the mouth, throat, vagina, or rectum, or when he has to touch an unclean wound——" You have seen this principle adopted in the wards. Gloves are used in dealing with septic cases, and sterilised towels or sheets are employed for the dressings, whether in clean or infected cases, just as is done in the operating theatre. A punctured glove is worse than useless. They should not be worn too well fitting; the constant elastic pull, as the fingers unbend, becomes tiresome. Gloves may, if preferred, be sterilised dry in the caddies with the dressings after being well powdered. When the hands are dried by treatment with alcohol, and the gloves sterilised in this manner, any leak that may occur from a prick of a needle or tear from a sharp fragment of bone during the operation, is not of so much moment, for now the leak is from the wound into the glove, and not in the reverse direction, as is the case when the gloves are filled with fluid to facilitate the entry of the hand. The glove should always be immediately changed, and the hands washed, if a tear occurs during an operation. Gloves complete the aseptic costume of the operator by being pulled over the ends of the long sleeves of a sterilised coat, so that no part of the arm is exposed.

Large sterilised sheets cover over the entire patient, and are fixed to the skin immediately round the area of operation by minute skin clips made after the pattern of the American bullet forceps used in gynæcological operations. These clips, which, unfortunately, are seldom properly made in this country, pinch the sheets and skin together without leaving a mark, and without causing pain even in a conscious patient. Formerly the sheets, if in the close neighbourhood of the incision, were apt to slip into the way. By means of these forceps this is now avoided, and a minimum area of skin need only be exposed.

Anæsthetics.—To obtain success in surgical cases the question of the most suitable anæsthetic to employ must be given due attention. Chloroform should not be used as a routine unless by skilled anæsthetists, and is then only advisable in children, in aged people with chest ailments, and where more perfect relaxation of the abdominal muscles is needed than can be obtained with ether. In giving chloroform be careful to stop the administration during such procedures as the dilatation of the sphincter ani, the grasping of the prepuce with forceps prior to circumcision, and whenever the patient struggles or holds his breath. In all these cases the patient may unexpectedly take a deep inspiration, and, if the chloroform is pressed, receives an overdose. Always give the chloroform well diluted with air, remembering that cyanosis is a danger signal, and that disasters from chloroform anæsthesia have often occurred after the first few breaths.

Ether you may safely give after a little practice, chest complications being the greatest fear, but these can be avoided by giving a minimum dose, having a clean apparatus, and by care in the transference of the patient to or from the theatre, the head being, as a rule, covered with a blanket to prevent inspiration of the cold air of the passages after, say, an hour's operation in a very warm theatre. You have seen recently ether by the open method administered to my operation cases, the last patient, a thin, fragile woman, having a fracture of the upper end of the femur. The ether was given by a continuous drop on to a Skinner's chloroform mask, the latter being packed round with wool and gauze so as to prevent unnecessary evaporation and dilution. The absence of cyanosis and after sickness was remarkable, but the time taken to put the patient under, and the amount of ether used, was, however, rather excessive. In a case of a plethoric individual addicted to the use of alcohol, we were obliged to resort to the Clover's mask to produce narcosis, and to continue by the open method. Ether by the open method is ideal in those patients where one hesitates to give chloroform, and fears the bronchitis following the use of a closed apparatus.

LOCAL ANÆSTHESIA.

It is with the question of local anæsthesia that I wish specially to deal. You have seen a large number of cases operated upon after a novocain injection, including hernia, hydrocele, varicocele, varicose veins, removal of lipomata, sebaceous cysts, enlarged bursæ, circumcisions, hammer toe, ganglia, and almost every operation which comes within the category of minor surgery. There are two methods commonly employed to produce local anæsthesia; the one, the infiltration method you have seen most employed, the other, the regional method, is sometimes superior. The solution used has been until recently made by dissolving the commercial novocain-adrenalin tablet in 7 drachms (25 cc.) normal saline solution or water. This makes a ½ per cent. solution. Lately, half this strength has been found adequate, and so for general infiltration work I recommend you to use a tablet dissolved in 50 cc., or about 14 drachms—*i.e.*, ¼ per cent. solution. A very fine needle, supplied by Smith and Sheppherd, Stephen's Green, about a finger's length, is attached to a glass syringe of 10 cc. capacity, so that the needle lies at right angles to the syringe and horizontally as regards the skin. Suppose, now, it is desired to remove a varicose vein. The needle is passed into the subcutaneous tissue along the course of the vein; the solution is then injected, keeping the needle pressed against the under-surface of the skin during its gradual withdrawal. While the needle is being withdrawn, the novocain is introduced *pari passu* in the manner mentioned. If the vein is not visible, it is well to mark its position with a little iodine solution or a scratch with the knife immediately before the injection, for fear that when the injecting needle is removed, there will be no indication where the incision is to be made, and it is imperative that the latter should correspond exactly with the site of the injection of the anæsthetic. As many as three tablets may be used with impunity—that is to say, 150 cc. of ¼ per cent. solution—but such an amount is never required. After an experience of three years I have nothing but praise for novocain as a local anæsthetic. It lacks the toxicity of cocain, and has all its advantages. Novocain solutions can be boiled without deleterious effects (the adrenalin will not stand boiling), and so a porcelain capsule and a spirit lamp are useful adjuncts to the appliances already mentioned. A solution of novocain may be used instead of the tablets, to which a few drops of adrenalin may be added after boiling.

There are some patients who bring discredit on local anæsthesia—those nervous, hysterical cases which we occasionally meet with more frequently in men than in women. Thus I brought you into the theatre the other day to demonstrate the failure of local anæsthesia in a man whose finger required amputation. The stroke of a blunt-nosed forceps caused excruciating pain! The operation was completed under general anæsthesia. But this case and one other—a woman with a ganglion on the wrist—are the only two failures I can remember. Undoubtedly the use of local anæsthesia entails more trouble to the surgeon; the tissues must be divided with accuracy; no pulling or tearing or indiscriminate grasping being permissible. For these and other reasons disappointment is often felt by those beginning extensive local anæsthesia work, but everything requires practice, from the insertion of a stitch to the performance of the most intricate surgical operations. Amputations of the fingers and toes are better performed by the "regional anæsthesia" method—*i.e.*, injecting in a strong novocain solution (1 per cent.) into the course of the digital nerves proximal to the site of amputation, and waiting about 10 minutes until the finger distal to the injection becomes anæsthetised. This is a very effective method, and the operation can be performed quite painlessly. Again, if the same solution be injected into the ulnar nerve behind the inner condyle of the humerus, or as near to the nerve as can be gauged, the distribution of that nerve will become anæsthetic in a few minutes, a nerve block occurring and preventing the transmission of afferent or efferent impulses for over an hour. Regional anæsthesia may be supplemented by infiltration of the tissues to be divided. Patients are grateful when an operation can be performed without a general anæsthetic; it often means, not only the disappearance of that dread with which so many yield to unconsciousness, but they can with advantage eat a good breakfast before operation, enjoy their meals later on, and can even assist the surgeon by changing their position to suit his requirements. It is remarkable to hear men telling stories and discussing current events while varicose veins, for example, are being removed.

It is unwise to discuss the question of local anæsthesia with the average hospital patient; it should be adopted as a matter of course, and it is also unwise to allow assistants or nurses to question the patient during the operation as to what sensations they experience; you will very soon be informed of the fact if your work becomes painful. Occasionally the patient can tell when a knife and when a needle is being used, but without experiencing pain.

I must refer you to the excellent work of J. W. Struthers for all the details on the subject. Local anæsthesia is now following Continental practice more extensively in this country. The question of spinal anæsthesia, also, is full of fascination, but time does not permit me to discuss the relative advantages and disadvantages of the method.

Prior to the discovery of novocain, a ½ per cent. solution of cocain was used for infiltration anæsthesia, but now, if cocain is employed, a 1 in 500 normal saline solution with adrenalin is found sufficient. Cocain and novocain differ from the majority of other local anæsthetics, such as β eucain, in having an almost instantaneous effect when infiltrating the tissues. I am aware that many authorities state that a delay of a few minutes is necessary when using novocain, but that is not my experience unless where regional anæsthesia is employed.

Crushing of Pedicles.—The use of angiotribes (histotribes), or crushing forceps, in operations was advocated by Kocher, and Doyen, working independently. They showed what great advantages were to be gained by the powerful crushing of pedicles before applying, or instead of applying a ligature. Last month you saw in a thyroidectomy case the isthmus of the gland thus treated, as also the stump of an appendix; the turning back of a peritoneal cuff being so much waste of time. If the crushed stump be tucked into the colon and thus covered with peritoneum, it is the most rapid and effectual method. I have demonstrated to you how crushing an appendix divides the mucous membrane as if with a knife. In fact, all the tissues are divided by powerful crushing except the fibrous tissue which is surrounded by the ligature. The division and retraction of the mucous membrane in this manner disposes of the necessity of cauterisation with, say, pure carbolic acid; a ligature is applied to the crushed portion, and the appendix cut away immediately distal to it. You remember, after removal, I have shown you many times how if a crushing forceps be applied to the appendix, and you then lay it open with a pair of scissors, you find inside the mucous membrane sharply divided and retracted, and the crushed portion consists of nothing but fibrous tissue, forming a snug groove for the application of the ligature. It is a common fallacy to suppose that necrosis is produced by crushing; certainly, in intestinal work it would be impossible to produce necrosis by powerful crushing; the tissues are, on the contrary, with the exception of the fibrous tissue, divided as with a knife. You have seen the sacs of herniæ crushed, the stumps after resection of varicoceles, the ends of the intestine after resection, and prior to lateral anastomosis. This is the most rapid manner too of closing the intestine; a powerful crushing forceps is applied, a silk ligature secured round the crushed portion, and the stump beyond the ligature inverted and covered by circular or a few Lembert sutures. This is the best manner, also, to treat the proximal end of the duodenum in the operation of pylorectomy, where it is decided to perform gastro-enterostomy and closure of the remains of the stomach. Wherever a large pedicle is to be divided, first crush it, for this procedure reduces its size to a minimum, and forms a groove for the ligature which prevents the possibility of slipping.

There is scarcely an operation in which a crushing forceps cannot with advantage be made use of. It must be powerful to be effectual, and should be at hand as a matter of routine for every operation.

Saline Solution.—In conclusion, I will remind you of the many advantages gained by the general adoption of the use of saline solution, not only for the mechanical purification of infected wounds to which I have already referred, but in abdominal surgery. In bad cases of septic peritonitis arising from perforated gastric ulcer, gangrenous appendix, strangulated hernia, and the numerous other conditions with which you are familiar, great reliance should be placed on the continuous injection of saline solution combined with the Fowler position. I will explain the *rationale* of this treatment in a moment. In almost every abdominal case the use of saline injection into the tissues or into the rectum are accompanied by the greatest gratification to the patient. Thirst is effectually diminished; the nurses seldom, since the use of saline is adopted as a routine, draw attention to the thirst which patients were wont to suffer. In infected cases the toxins by this treatment are eliminated by increased diuresis, sweating, frequent action of the bowels; and by reversing the peritoneal lymphatic flow, their entrance into the circulation is impeded. At the same time the pulse tension is maintained, the tongue becomes moist, the facies Hippocratica disappears, and the mortality has been reduced in an astonishing way under its influence.

Some years ago I brought from Kocher's clinic in Berne the flask which you have seen so frequently used in the administration of saline solution, either into the tissues or into the rectum; this flask has more recently been adopted by Moynihan and other surgeons. It consists of a glass graduated vessel with a litre capacity into which fits a tight rubber cork with three holes. Through one passes a large thermometer, and the other two are traversed by glass tubes, one for the outlet of saline solution, the other for a corresponding inlet of air. From the former passes a rubber tube, about three feet long, to which is attached the hollow needle used for intra-cellular transfusion, or in the case of administration per rectum, a long flexible leaden tube perforated at the sides, lest fæces block the terminal orifice. This apparatus can be sterilised, complete, and during use the exact temperature of the solution can be read off; and maintained or diminished by placing the flask in a basin of water at the required temperature. By altering the water in the basin the temperature of the saline solution in the flask can be varied.

Sometimes during an operation involving much hæmorrhage, or the loss of a considerable amount of fluid as in cases of ascites, saline is allowed to slowly flow into the cellular tissue of the axilla or the outer side of the thigh, the flask being supported on a douche stand. After bad abdominal operations both axillæ are infiltrated through the needle with saline solution from the flask to the extent of about one pint into each armpit. When the patient revives after the anæsthetic, the long leaden tube is passed well up into the pelvic colon, and saline solution is allowed to trickle in, drop by drop, as recommended by Murphy; it is absorbed as quickly as it enters, and very large quantities are thus consumed. The flask need only be raised a few inches above the level of the patient's pelvis to promote sufficient flow. The temperature of the saline is kept constant at about 110° F. by renewing the hot water in the basin in which the flask stands. In children this continuous saline administration is not suitable, the sensation of the inflow into the bowel gives rise to an impulse to pass it out, and so the saline is not retained. In these cases, for example, the patient in the children's ward on whom I performed an emergency laparotomy for perforated colon following tubercular peritonitis, the method failed, and instead, abandoning the flask, we administered, at frequent intervals, intracellular injections simultaneously into both thighs by means of two needles attached to a funnel.

I think, after every abdominal operation, a saline should be administered as a matter of routine, but in acute suppurative cases the administration should be continuous for several hours and repeated after a short interval. In these cases, also, the Fowler position should be adopted, the patient being placed semi-sitting, so that the pus present may gravitate from the diaphragm towards the pelvis, from a position where absorption is rapid to a position which is fairly tolerant to the presence of pus. In this connection the manner in which cases are removed from, or to, the operating theatre is of primary importance, the direction of least resistance for the gravitation of the pus must be the pelvis where drainage tubes are provided for its exit.

In many cases other than abdominal, such as pneumonia following operations, extensive burns and all the affections producing toxæmia, frequent administration of large quantities of saline solution have afforded, for the reasons mentioned, most gratifying results.

Closure and Dressing of the Wound.—Michel's clips are always used where there is no tension. The angles of the incision are held up by means of two sharp hooks; the edges are then squeezed together with the finger and thumb of the left hand, and the clip inserted. Two forceps should be employed for the introduction of these sutures, the sister loading one while the other is actually in use. By this means, after a little practice, the closure of a wound becomes very rapid. Metal clips which are too pliable are worse than useless. I have had endless trouble in obtaining the correct variety. I have tried, and abandoned, the use of complicated self-loading instruments. Where it requires tension to bring together the edges of an incision, continuous silk or interrupted silkworm gut sutures are preferred. In uniting the abdominal parietes in young children, a single layer of the latter is used, but first each silkworm gut suture, following the fashion of Stiles, is passed through the finest possible piece of rubber tubing about an inch long. When the suture is tied, the tubing lies across the line of the incision, and prevents a transverse mark or cutting of the skin. The tubing is useful in these cases, for a single layer of sutures should remain undisturbed for nearly three weeks. The wounds are all dressed in the following manner:—A piece of folded gauze the length of the incision, and about a finger's-breadth, is laid along the incision over the sutures. This is held in position by a single layer of the same material which covers it and extends beyond it on all sides, and is painted lavishly with collodion with an ordinary sterilised paint brush. The collodion does not come into contact with the wound, but secures the dressing, and makes a very aseptic and reliable covering. Wool and a bandage may be added in certain cases, but, as a rule, are not required. Iodoform steeped in collodion (1-1000) is always at hand for wounds which are in danger of subsequent infection, such as hernia in children. The iodoform dries on the wound, and mechanically prevents the entrance of micro-organisms.

In all matters affecting technique it is necessary to have the co-operation of the nursing and resident staff, and in this I have been fortunate, for without the aid of our recent House Surgeons, especially Dr. Hunt and Dr. Arthur Knapp, the theatre sister and the nurses generally, I could have accomplished nothing.

There are many other points to which I would like to refer, but the time at our disposal is already at an end.

NOTE.—***A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Cuthbert Lockyer, M.D., B.S., F.R.C.S., Out-Patient Physician, Samaritan Hospital for Women, Obstetric Physician in Charge of Out-Patients, Great Northern Hospital, etc. Subject: "Cancer of the Uterus."***

THE KING has sent a present of pheasants to the Chelsea Hospital for Women.

ORIGINAL PAPERS.

NOTE ON
THE PATHOGENY OF DIABETES.

By S. A. ARANY, M.D.,
Carlsbad.

Since Claude Bernard discovered in 1855 that the lesion of the calamus scriptorius of the fourth ventricle is followed by the appearance of sugar in the urine, the authors of that and the following decades were unanimous in considering diabetes as being caused by some pathological changes in the brain or in other parts of the nervous system. Further researches have shown that the puncture operation causes a decided diminution of the glycogen contained in the liver, and glycogen flows off in the shape of glucose with the urine. In starving animals whose liver does not contain glycogen, the puncture cannot produce any glycosuria. Bernard's experiment proves undoubtedly the influence of the nervous system upon the liver, but, on the other hand, injury to the liver without the puncture is also apt to produce glycosuria, and Murchison ("Clinical Lectures on Diseases of the Liver") points out the connection between cirrhosis of the liver and diabetes. Naunyn ("Der Diabetes Mellitus"), confirming Murchison's view, claims that, out of 426 cases of diabetes, in 109—viz., in more than 25 per cent.—enlargement of the liver was present.

Almost a century previous to Bernard's famous puncture, Cowley called attention to a serious case of diabetes in which partial atrophy of the pancreas was present, and he therefore claimed the diseased condition of the latter organ to be the cause of diabetes. Cowley's opinion was shared by many others, but it was not till the year of 1889 that it was corroborated by Mehring and Minkowski's ("Archiv. fur. Exper. Pathologie and Pharmacologie," XXVI.) experiment of extirpating a dog's pancreas, and this resulting in a diabetic condition of the animal. Minkowski's experiment has been tried by several authors, and they have found that only the total extirpation of the pancreas is able to produce a diabetic condition; whereas if even a very small portion of the organ is left behind no diabetic symptoms appear. This discovery led the authors to the belief that the assimilation of carbohydrates must be due to some function of the pancreas, which if in a diseased condition gives rise to diabetes.

The kidneys are supposed to be a third source of sugar, and although this has by no means been confirmed, a good many German authors—and amongst them Naunyn—are strongly in favour of this theory. It was the diabetic condition of animals injected with phloridzin which led to the belief that the kidneys themselves are able to produce diabetes. Animals thus treated pass a good deal of sugar with their urine, and at the same time there is no trace of hyperglycæmia present, whereas after the puncture operation and the extirpation of the pancreas, the glycosuria was always accompanied by hyperglycæmia. Having this fact in view, the authors concluded that the source of the sugar must be in the kidneys.

This may or may not be the case in phloridzin diabetes, but if we go through the literature of kidney troubles, we find that there are only solitary cases of kidney disease followed by the appearance of diabetes. Moreover, we find—and even Naunyn confirms this fact—that Bright's disease is very often a complication of diabetes, and soon becomes the predominant ailment, whereas glycosuria gets reduced to almost nil. Noorden ("Handbuch der Pathologie des Stoffwechsels"), who takes a more doubtful view as to the existence of renal diabetes, thinks that in the so-called renal diabetes the kidneys cease to be "sugar-proof" (*zuckerdicht*), and may thus be instrumental in producing glycosuria.

Mention must also be made of Blum's researches ("Nebennierenglycosurie Deutsch. Archiv. für Klin. Med.," 1901) to the effect that an extract of the suprarenal capsules is apt to produce glycosuria. Herter and Richards ("On Glycosuria Following the Injection of Adrenalin," *Med. News*, 1902) have shown that Blum's extract is but adrenalin, and Noorden cites a case of glycosuria which has been brought on through the administration of adrenalin, and rightly ascribes the glycosuria to the toxic action of the drug.

According to present-day knowledge, the organs which are instrumental in producing diabetes—or, to use the German author's expression—the diabetogen organs, are the following:—(1) The brain and the nervous system; (2) the liver; (3) the pancreas; (4) the kidneys; (5) the suprarenal capsules.

Now, everyone who had to deal with a large number of diabetic cases, and was fortunate enough to see his observations *intra vitam* confirmed by post-mortems, will admit that in a great majority of the cases the diabetogen organs are found to be either normal, or pathologically changed in a lesser degree, and which changes might possibly be brought on by the disease itself—viz., by the hyperglycæmia. If it were not for the presence of the hyperglycæmia, the cases in which no pathological changes are present could be styled, with the German authors, as renal diabetes, as, according to them, the very existence of glycosuria with no changes in the other diabetogen organs is, *ipso facto*, renal diabetes, whether there are or are not diagnosable changes in the kidneys. Be this as it may, the existence of glycosuria without hyperglycæmia seems to be very unlikely. Our tests for this latter are almost unreliable, and the non-existence of hyperglycæmia at the time of the test does not necessarily prove that it did not occur at all. Besides, we are far from knowing the exact amount of sugar contained by normal blood. It is doubtless that diabetes is always accompanied by hyperglycæmia, which in its turn is responsible for glycosuria. The non-existence of the former in phloridzin diabetes cannot be considered a proof to the contrary; it only tends to show that phloridzin does not produce any discoverable changes in the blood, although other toxins, as curara, morphine, strychnine, carbo-oxide, etc., produce hyperglycæmia. Autopsies of the literature show that lesions of the fourth ventricle and of the nervous system in general are very rarely the cause of diabetes, although we are all aware of the fact that the nervous system is undoubtedly involved in the pathogeny of diabetes. Mention has already been made of the connection between kidney disease and diabetes, and as far as liver complaints are concerned, we know that cirrhosis of the liver and gall-stones do not infrequently coincide with diabetes; but, on the other hand, there are far more cases of liver disease in which glycosuria cannot be traced. The liver of diabetics shows, as post-mortems reveal it, either no changes at all, or, if there are any, they are mostly of a cirrhotic nature, although fatty degeneration is not of infrequent occurrence.

As far as the glycogen of the liver is concerned, the amount of the same is just as often found decreased as normal, and if Frerich's experiment ("Zur Kenntniss des Meuschlichen Glycogens") of testing the glycogen of diabetic patients, *intra vitam*, is to be trusted, the amount of glycogen is usually diminished in diabetes.

Pathological changes of the pancreas occur more frequently, and they are only too readily looked upon as the producers of the disease. In the majority of cases these changes prove to be atrophic, and it remains to be proved whether this latter is not of a secondary origin. How little importance has to be attached to the diseased condition of the pancreas is clearly defined in Hale-White's "Diseases of the Pancreas and Diabetes" (*Lancet*, March, 1903), in which the author points out that, out of 142 cases of pancreas disease, only in 19 cases was diabetes present. Since Minkowski's experiment of extirpating the pancreas, nobody will doubt that the pancreas has something to do with producing diabetes, but the experiment does not entitle us to state that the pancreas is to be looked upon as the seat of the ailment. We know that brain tumours are apt to produce optic atrophy, but it does not necessarily follow that every optic atrophy is due to a brain tumour. The physiological functions of the pancreas are far from ascertained, and all we know about this gland is that it plays an important part in the assimilation of carbohydrates. In what way this function is performed is, in spite of the many theories of various investigators, quite obscure. The theory of an internal secretion performing the act of assimilation seems to be the most likely, and Minkowski's experiment is also in favour of it. Neither experiments on animals nor post-mortems give any clue as to how this function is controlled in diabetes, and all we can conclude from the post-mortems is, that in about 1-5th of the diabetic autopsies some pathological changes are found in the pancreas, but, in contrast, to these, there are a vast number of cases of pancreas disease in which no diabetes was traceable *intra vitam*. Does this not entitle us to suppose that the pathological changes of the pancreas in diabetes are of secondary origin—*i.e.*, brought on by the disease itself.

Whether there are, or are not, pathological changes in the diabetogen organs, whether this or that organ may be involved, one fact holds good—viz., that, at all events, hyperglycæmia is present. Hyperglycæmia is the direct cause of diabetes, and is even in such cases established in which the glycosuria has disappeared. Therefore, the theory of renal diabetes appears to be quite illusory, and there is no doubt that also in these cases there is an excessive amount of glucose in the blood, and if the investigators could not establish it, that is solely due to the inadequacy of the methods, and to the fact that opinions differ as to the exact amount of sugar contained by normal blood. This latter amounts, according to Pavy's investigations, to 1.5 per cent., whereas Naunyn and Noorden put it below 1 per cent., and I am strongly convinced that in certain cases even much lower values may be looked upon as hyperglycæmia, and in other cases values above 1 per cent. may be regarded as normal, as the limit between the two depends upon the individual case.

Taking it for granted that the hyperglycæmia is the cause of diabetes, the question arises, "What is hyperglycæmia due to in human diabetes?" Bernard Claude's famous puncture, and Minkowski's operation, only show how we are able to produce hyperglycæmia, and where to look for the centres which are responsible for the control of carbo-hydrates. But what about such cases in which our pathological knowledge cannot discover any appreciable changes in those centres? Is it not obvious that even if we can't disclose the changes, such must be present? And is it not probable that if the changes cannot be proved anatomically, they could possibly be established by bacteriological and chemical methods? Is it not more than likely that the hyperglycæmia is a certain kind of toxæmia brought on by some unknown bacterium?

We have seen that the administration of phloridzin produces glycosuria without hyperglycæmia, but, on the other hand, we also mentioned that some chemicals, as morphine, strychnine, etc., are able to produce temporary hyperglycæmia, and we don't think we are going too far in presuming that there must be a toxin which is responsible for the causation of human diabetes. This toxin, which for brevity's sake we beg to call glycotoxin, is most likely produced by a bacterium which may or may not be present in the digestive organs of healthy individuals, and which, if brought under favourable conditions, is instrumental in producing the glycotoxin. The action of the glycotoxin cannot be uniform, and necessarily depends upon the virulence of the toxin. In the alimentary or mild form of diabetes, as other authors call it, or in the first stage of the disease as I ("The Treatment of Diabetes Mellitus," *Medical Press*, March, 1905, and "Diabetes and Its Treatment," *The Indian Lancet*, May, 1905) call it if the glycotoxin represents the lowest degree of virulence, and its action consists in destroying to a greater or lesser extent the glycolythic ferment of the pancreas and in producing the condition known as hyperglycæmia, this action of the toxin is very likely of a local and purely chemical character, and seems to depend upon the ingestion of carbo-hydrates. The withdrawal of these latter surely attenuates, and in some cases probably annihilates the virulence of the toxin, which also accounts for the possibility of a cure.

In other cases the symptoms of diabetes diminish for a more or less protracted period, to resume again with greater violence, which shows that the toxin has increased in virulence, and the disease represents the grave form, or, as I ("Dietary in Diabetes and Gout," *The Medical Press*, January, 1906; "Some Points in Diabetes," *The Lancet*, February, 1907) call it, the second stage of diabetes. At this stage of the disease the sugar contained by the blood is not only derived from the carbo-hydrates ingested, as we know that the withdrawal of the carbo-hydrates is not followed by any appreciable reduction of the hyperglycæmia, but also and chiefly from the breaking down of bodily tissue, which is proved by the presence of oxybutyric acid.

This catabolism speaks undoubtedly in favour of the toxic nature of the disease, and so do the acidosis and its consequence—the diabetic coma. The oxybutyric acid appears not only in diabetes; we also meet with it in various infectious diseases, as Külz ("Beiträge zur Kenntniss der B. Oxybutter-säure Zeitschr.-für Biologie," Bd. XXIII.) has shown it, and no doubt can be entertained that its appearance in the blood is due to reduced oxydation, which latter is, it goes without saying, also responsible for the hyperglycæmia. This course seems to be quite clear if we bear in mind that most toxins produce reduced oxydation, and as far as acids are concerned Naunyn ("Der Diabetes Mellitus") and others have proved it that besides retarding the oxydation, acids are also apt to produce glycosuria. It is, therefore, highly probable that the glycotoxin's action chiefly consists in producing acids of some kind or the other, which in their turn are responsible for the retarding of the process of oxydation.

We know that the assimilation is but a process of oxydation, and this seems to be largely dependent upon the alkalinity of the blood. Now, if the alkalinity of the blood is being reduced by the glycotoxin, the glycolithic ferment will, as a matter of course, be either partially or totally prevented from performing its action, and the condition known as hyperglycæmia ensues. The fact that in the alimentary form, or, as I call it, in the first stage of the disease, oxybutyric acid cannot be traced, does not necessarily imply that the hyperglycæmia is not due to the reduced alkalinity of the blood, as the absence of oxybutyric acid does not exclude the presence of some other acids, which our inadequate methods of blood-testing so far could not precisely establish.

The toxic nature of the disease is most clearly proved by the so-called acute cases which terminate fatally through coma in the course of a few weeks, and sometimes in a few days, and which I suppose to be produced by the glycotoxin of the greatest virulence.

The acidosis attains its height in the condition known as diabetic coma, which, according to present-day conception, is due to the action of the oxybutyric acid upon the blood. Whether this action is due to the oxybutyric acid only, or to its derivants, the diacetic acid and acetone as well, has not been decided yet, although Albertoin and Pisenti ("Azione dell' aceton e dell' acido acetacetico. Arch. d. la scienz. med.," XI., 1887) have shown that even as large doses of acetone as 2 drachms per diem could not produce symptoms of intoxication in rabbits by the continuous administration of the above dose for three weeks. On the other hand, Walter ("Uber die Wirtenng. der Säuren im tierischen Organismus. Exp. Path. Archiv. 7, 1877) succeeded in producing typical coma in rabbits through the administration of large doses of hydrochloric acid, which experiment justifies the supposition that the oxybutyric acid is not necessarily the only producer of coma, and in case of the improvement of our present methods of blood-testing, I should not be at all surprised to hear that the oxybutyric acid is only a derivant of an acid of far greater virulence than the former.

An unmistakable proof of the toxic nature of diabetes is Roque, Dévic and Huguenecq's experiment ("Coma diabetique, Revue de Médecine," 1892), but it is to be regretted that they only took the acidosis into consideration. The above authors injected the blood of a comatose patient into the veins of rabbits, and produced thereby toxic symptoms of the utmost severity; whereas if they increased the alkalinity of the blood injected, the toxic symptoms appeared to be of lesser intensity. Lépine succeeded in crystallising a substance ("Diabète produit par toxines uriques") from the urine of diabetic patients which, if injected into veins of dogs, possessed the quality of producing glycosuria. It would have been of great interest if these authors had investigated the toxic action from a bacteriological point of view, and it is more than likely that researches in this direction will sooner or later establish the bacterial nature of diabetes.

The fact that the diabetic blood, if its alkalinity has been increased, acts less toxically, does not imply that the blood acts only through its acidity as a toxin. All of us who have had to deal with cases of diabetic coma well know that the administration and intravenous injection of alkali are able to delay the appearance of coma, but cases in which these drugs could prevent the appearance of coma are not described in literature. On the other hand, Riess ("Coma diabetram sine diabete Zeitschr. für Klin. Med.," Vol. VII.) and others have described typical cases of coma in carcinoma, pernicious anæmia, and other diseases, in which emaciation takes place, and in which diabetes has been excluded, and it is a very well-known fact that profuse bleeding also produces a condition which is quite identical with diabetic coma. Taking all this into consideration, one arrives at the conclusion that coma must be produced by some changes in the blood, and it becomes quite evident that it is not only the reduced alkalinity of the blood to which the coma is ascribable, as such is surely not the case in coma produced by bleeding. The fact that carcinoma and pernicious anæmia are able to produce coma admits the supposition that also in diabetic coma there must be a toxin of far greater virulence than that of the organic acids found in the blood of diabetics, and which toxin not only reduces the alkalinity of the blood, but also produces some changes in the blood corpuscles, as is surely the case in pernicious anæmia.

The question of diabetes being a contagious disease has been discussed by various authors, and Boisumeau ("Diabète des mar., Gazette hebd.," 1897) mentions 101 cases of diabetes of married couples, and Schmitz ("Kann. der Diabetes übertragen werden?" *Berl. Klin. Woch.*, 1890) refers to 26 patients who have seemingly enjoyed robust health until they acquired diabetes through friendly intercourse with diabetic patients. Still more interesting is Naunyn's case ("Der Diabetes Mellitus"), referring to a young lady who stayed for a time with friends—*i.e.*, a married couple, both of whom were sufferers from diabetes, and acquired the disease, which, however, assumed only a transitory character. I myself have also had 10 married couples suffering from diabetes in my care, but am rather doubtful as to the contagious nature of the disease.

As far as heredity is concerned, it must be admitted that it is to be traced in at least one-fifth of the cases of literature, and everybody who sees a good deal of diabetic patients has had occasion to treat several members belonging to one and the same family for diabetes. However, this fact must not be misunderstood, as it does not signify that diabetes, as such, is hereditary; it only allows of the supposition that there must be a predisposition for diabetes in certain families. This predisposition, which, as we know, is not peculiar to diabetes only, but plays a very prominent part in tuberculosis as well, may be transmitted from parent to child. On the other hand, in four-fifths of the cases heredity cannot be traced, and there are also many instances in which the descendants of diabetic parents never showed any symptoms of diabetes, which entitles us to assume that, although it cannot be denied that there is a diabetic predisposition in certain families, diabetes may attack anyone whose constitution does not prove resistant against the toxin of diabetes.

The almost general belief that Jews are more prone to diabetes than the other races is by no means justified, and originates from the fact that we consulting physicians see a good many cases belonging to the Hebrew faith. This is, however, no criterion for a just percentage. Everybody having an international practice must have noticed that the lower classes of Jews are, very likely owing to their great intelligence, more mindful of their health than the lower classes of other nations. My international practice has shown me that if a very poor Polish Jew notices the first symptoms of diabetes, he immediately sees his local doctor, and if this latter advises him to go to Carlsbad, he is quite willing to do so, even if he has not got more than 40s. in his pocket. On his arrival at Carlsbad, he would inquire and find out the name of "the best doctor" in town, as he feels sure his case requires the advice of "the greatest authority," no matter whatever his fee is, as the Polish Hebrew is quite aware of the fact that no authority can make him pay. This ambition to get well by all possible and impossible means accounts for the seemingly large percentage of Jewish cases, but it is a quite erroneous idea that Jews are more prone to diabetes than other races.

In summing up the facts we have discussed in the present treatise, one arrives at the following conclusion:—That, whereas lesions to or the removal of some of the so-called diabetogen organs are apt to produce diabetes in animals, in the majority of cases of human diabetes there are no changes in the diabetogen organs, the chief feature in common between the two kinds of diabetes being in the hyperglycæmia only, which condition can also be produced by certain alkaloids and acids. It has further been pointed out that the appearance of acids in the blood of diabetics is a simultaneous phenomenon of the disease, and as physiological researches have proved that the appearance of acids in the blood retards the process of assimilation, the loss of the assimilation of carbohydrates in diabetes is probably due to the appearance of such acids. It is also highly probable that the production of these acids is effected by a toxin produced by some unknown bacterium which may or may not be present in the system of the healthy individual, and which, if brought under favourable conditions, is apt to produce human diabetes.

In spite of the fact that there are a few cases in literature in which diabetes attacked married couples, and, in spite of the evidence of some authors that in certain cases the contagious origin of the disease seemed to be traced, it would be too early to allege that diabetes is a contagious disease, as the number of cases referred to is diminishingly small in proportion to the very much larger number in which contagion could not be traced.

In conclusion, it must be admitted that, although there is a so-called diabetic predisposition in certain families, diabetes, as such, cannot be inherited, and the belief that certain races are more prone to it than others is also quite erroneous, and is only due to misjudged statistics.

LETTSOMIAN LECTURES, 1908.

TUBERCULOSIS OF THE KIDNEY. (a)

By CHARTERS J. SYMONDS, M.S., LOND., F.R.C.S.,

Surgeon to Guy's Hospital.

After paying a tribute to the memory of Dr. Lettsom, and thanking the Council for the honour they had done him in requesting him to deliver the lecture, he explained that the object of the first lecture was to relate the particulars of cases illustrating the early signs of renal tuberculosis and the effects of the operations performed.

Of the early symptoms the first to which attention was called was that of renal colic. A typical instance was the case of a young lady of twenty, who had the first attack two years before, the second a year after the first, and the third just before she was seen. In the interval she had been in apparently good health. Albumin was found to be present three months before she was seen, together with a little pus in the urine. The case was looked upon as one of renal calculus. Tubercle bacilli were examined for specially after the X-Rays gave a negative result, and were found. The cystoscopic examination showed tuberculosis of the bladder round the right ureter, with swelling of the ureteric orifice, the left side being healthy. On this evidence the right kidney was removed, the ureter being left, partly because the patient had recently suffered from an attack of scanty urine; partly because she was delicate and it was unwise to prolong the operation; and, finally, for fear that prolonged narcosis might be injurious in the presence of inadequate renal action.

(a) Abstract of Lecture I, delivered before the Medical Society of London, February 3rd, 1908.

The kidney showed an old tuberculous centre in the lower pole, evidently of long standing, with fresh miliary tubercles in the cortex and in the pelvis. Under tuberculin treatment this patient has completely recovered.

To further illustrate this initial symptom. A patient of 46, who had been out of health for two years, with no localising symptom, had a sharp attack of renal colic, followed by vesical irritation. He had a second attack in every way typical of renal colic, and it was thought that a small calculus had passed into the bladder. Nothing being found on examination, the urine was examined for bacilli, and these were found in fair numbers. The cystoscope showed a healthy bladder, with prolapse and œdema of the right ureteric orifice. The kidney, being removed, showed old cicatricial disease with marked contraction of the lower pole. This evidently was of long standing, and probably explained the early malaise. There was recent miliary tubercle in the cortex and in the pelvis. All the bladder irritability disappeared after the operation.

Next, vesical irritation as the only symptom was illustrated by the case of a young woman who had this trouble alone for twelve months, varying in intensity. There was no unilateral kidney pain. The bladder was found by the cystoscope quite healthy; the lips of the right ureteric orifice were swollen and marked by small white elevations. The kidney was removed and showed extensive disease of the lower half, with fresh clumps of tubercle in the cortex and the pelvis. The ureter was removed at the same time, and a rapid recovery followed, with immediate disappearance of all the symptoms.

In a lady of 40 the only symptom complained of for at least two years, and possibly for five, was from time to time an abdominal uneasiness, hardly amounting to pain. This sensation occurred chiefly in the night, lasted about an hour, was followed by a bad night's rest and a day of lassitude. Nothing was found on examination. Subsequently vesical irritation began, and later tubercle bacilli were found. Search was specially made for these because of the large amount of albumin in the presence of a little pus. In this case the bladder showed miliary tuberculosis and tuberculous ulceration near the right ureteric orifice, but the margins of the aperture were normal and the efflux of urine clear.

On this evidence tuberculin treatment was carried out, but without improvement. After ten months' treatment the patient suddenly became ill with high temperatures, rigors, passed a large quantity of pus, and developed a large painful renal tumour. Nephrectomy was performed, the ureter being left. The kidneys showed several cavities filled with pus; obliteration of the greater part of the pelvis with one ulcerated channel leading from some of the larger cavities to the ureter. The appearance suggested long duration and a recent communication between the pus cavities and the ureter.

The last case related was that of a lady of 30, who, after more than a year's vesical irritation, without any renal pain, was seized with rigors and hyperpyrexia. Coming under Mr. Symonds' care, after two months' illness, she was found very emaciated, delirious, and exhibited all the signs of septicæmia. The urinary tract being suspected, an abdominal exploration was made, and the left kidney found to be somewhat enlarged. Exposed and incised through the loin, pus was evacuated, followed by subsidence of all the symptoms. After a time the kidney was removed, and proved to be tuberculous. The loin, sinus and bladder symptoms persisting, the whole ureter was removed, and the patient made a complete recovery, being at the present time (ten years from operation) quite well.

The principal points commented upon in the lecture were the necessity of examining the urine in cases of renal colic in young people; the importance of vesical and urethral irritation as a symptom of renal disease, and especially of tuberculosis; again, that renal tuberculosis should be suspected when the amount of albumin in the urine is of greater amount than can be explained by the pus.

A special tribute was paid to the value of the cystoscope, and reference was made to papers read before the Society by Mr. Hurry Fenwick, and the lecturer acknowledged the help he had obtained in this regard from Mr. Pardoe.

Charts showing the opsonic index in two of the cases, where the tuberculin treatment had been carried out by Dr. Eyre, were also exhibited, together with lantern slides and water-colour drawings of the kidneys removed, as well as the specimens themselves.

SOME NOTES ON

INFANT FEEDING. (a)

BY HUBERT ARMSTRONG, M.D. VICT., CH.B.; M.D. LIVERPOOL;

Assistant Physician, Liverpool Infirmary for Children.

THE subject of infant feeding is a very extensive one, and with the time at my disposal limited, my intention now is only to touch upon one or two points which have been impressed upon me by a growing experience at the Liverpool Infirmary for Children, and to which I hope it will not be a waste of your time to listen.

Now, before a medical audience, I should like to leave unsaid that though there are many imitations, and many so-called foods that are very far from being imitations, there is no real substitute for the mother's milk. But the fact remains that in my experience cases are not infrequent where, according to the mother's statement, the infant has been taken from the breast under medical advice on what have appeared to me entirely insufficient grounds. I lay stress on the "according to the mother's statement," because it may so easily be a perversion of the truth. So many women only want the excuse to refrain from this somewhat irksome duty that, when consulted by one for the first time, I am sure it is better not even to mention the possibility of weaning, for fear of one's words being twisted to suit her inclinations. If the mother thinks her child is not thriving on the breast, have the infant weighed, and the weight recorded, regulate the woman's diet and habits, and—most important—the frequency with which she suckles the baby. This, of course, should be two-hourly during the first month, every two and a half hours during the second and third, and three-hourly subsequently. Too prolonged intervals, commonest among the upper classes and women who have to go out to work, render the milk too watery, tax the infant's staying powers, and are just as bad as too frequent nursing, a common fault among the poor and a very potent source of infantile dyspepsia. Haste must also be avoided: each feed should take from fifteen to twenty minutes. Constantly the insistence on regularity in these matters, particularly the frequency, is all that is needed to convert a whining, fretful baby into its mother's delight by day and the father's joy at night, while an increase in the weight will both gratify you and justify your resolution not to be responsible for unnecessary weaning.

(a) Read at a meeting of the North Wales and Lancashire and Cheshire Branches of the British Medical Association, at Chester, on April 10th, 1907.

Let us suppose a loss in weight, or some other legitimate reason for weaning; what is to be done? Now, if you read the latest and most up-to-date works on infant feeding, you would be led to imagine that there is but one hope for the alimentary salvation of such a child (putting aside the nowadays extinct "wet-nurse"), and that lies in a more or less complicated mixture, manufactured in a laboratory specially devoted to the purpose. This is the sort of prescription you must write:—

℞ Fat	3.25	per cent.
Lactose ...	6.50	,,
Whey proteids	0.75	,,
Caseinogen ...	0.40	,,
Alkalinity ...	5.00	,,

Eight feeds of six ounces. Interval 2½ hours. (*b*)

All this is not really so complicated as it appears, if you had your laboratory. Undoubtedly the percentage method is the most scientific, and in time to come will be the one we shall employ whenever possible. It is also the most expensive; in addition it is, in all except perhaps a very few cases, quite unnecessary.

In the large majority of cases there is no need for anything more than a simple moderate dilution of ordinary good cow's milk. Milk from one cow is quite unnecessary—rather, in fact, to be deprecated, as more liable to vary than the average of a herd. The fresher it is the better, and of course it must neither have been deprived of its cream nor had any preservative added. I have here a table I drew up some time ago, which was approved by my colleagues at the Children's Infirmary, and is in daily use among the out-patients there. The keynote is simplicity.

Age.	Number of Feedings in 24 Hours.	Interval between Feedings in Day Time. Hours.	Number of Feedings at Night. 10 p.m. to 7 a.m.	Quantity for each Feeding. Milk. Table-spoonfuls.	Water. Table-spoonfuls.	Sugar. Tea-spoonfuls.	Total quantity of Milk in 24 hours. Table-spoonfuls.
1st week... ...	10	2	2	1	2	⅓	10*
2nd to 4th weeks	10	2	2	1½	2½	½	15
2nd month ...	8	2½	1	2	3	½	16
3rd ,, ...	8	2½	1	3·5	3	½	32
4th ,, ...	7	3	1	5	3	1	35
5th ,, ...	7	3	1	6½	3	1	45½
6th ,, ...	6	3	0	9	3	1	54
7th ,, ...	6	3	0	10	3	1	60
8th ,, ...	6	3	0	11	3	1	66
9th ,, ...	6	3	0	12	3	1	72

* Twenty tablespoonfuls make half a pint.

During the first week 1 tablespoonful of milk to 2 of water is given; to the end of the first month, 1½ of milk to 2½ of water; during the second month, 2 of milk to 3 of water; and this last figure (*i.e.*, 3 tablespoonfuls of water) remains unaltered for the rest of the bottle-feeding. At the beginning of the third month 3 tablespoonfuls of each are being given, and the milk is gradually increased in amount; at the beginning of the fifth month it is 6 to 3; by the sixth, 9 to 3; and by the ninth, 12 to 3. Of course each bottle is suitably sweetened; and if the total quantity proves insufficient in the case of any particularly lusty infant, more may be given, preserving the proportions. I do not pretend that this is "humanising" the milk. It is *not*. The proteid content is far higher than in human milk. But if with the proportions given you combine ordinary cleanliness in the storage, in the bottle and teat, etc., and a rigid insistence on the regularity in times of feeding mentioned before, as a rule the child's digestion will cope with the excess.

Do not be misled by a little vomiting or "possetting" into altering the proportions of milk and water without first appealing to the weighing machine. If the child is putting on weight, there is no need to worry about the former.

For better-class patients who can afford fresh cream, the latter may be substituted for a proportion of the milk, or, if it agrees well, added with advantage to the bottle constituted as mentioned.

Babies are like many an adult in one respect; for one thing they do not like in large quantites is *water*. Too great a dilution is one of the most frequent causes of dyspepsia and wasting. We are all constantly seeing cases in which a child (say of 4 or 5 months) is getting 2, 3, or 4 of water to 1 of milk. Consider the amount of water with which the poor thing is deluged in order that it may get the insufficient nourishment in the attenuated mixture. In actual cases of this sort I have calculated that infants have been given 10 to 12 ounces of milk a day when they should have been having 20 to 30. Small wonder they wasted, and less that their tired stomachs resented the hydropathic treatment they were undergoing! Whole milk is far more likely to agree than these excessive dilutions.

Small doses of hyd. *c.* creta (apart from any syphilis) have often a beneficial effect if there is a little tendency to vomiting, with curdy stools—say, quarter or half a grain, with an equal amount of rhubarb and bicarbonate of soda, three times a day. Another powder which I have found of use, though more in acuter cases of vomiting, and combined with a temporary cessation of feeding, is one of bism. carb., gr. iij.-iv., and calomel, gr 1/20-1/12, three or four-hourly.

If the child feeds pretty well but does not gain weight, a teaspoonful of lemon or orange juice, sweetened, once a day, will often produce the desired result. I find myself, and indeed it is the experience of most, that the systematic weighing of infants is a great aid in guidance as to how much of mothers' statements to believe. Many mothers, especially first ones, are unduly pessimistic. It also acts as an incentive to the mother to follow up one's directions thoroughly when she sees the visible result as recorded by the scales.

Some babies seem to get tired of the unvaried diet of milk and water. In their case the addition of a teaspoonful of Mellin's food to one or two bottles in the day will tempt their jaded appetite. The same addition also may be made as a corrective of constipation, but there is no need for Mellin's or any other food *as a food*, till at least the seventh month. They are so consistently

---

(*b*) From "Nutrition of the Infant," Vincent. 2nd Edition. 1904.

followed by rickets when given before that age that, although some are worse than others in this respect, they are all better avoided.

Personally, I prefer the milk *not* sterilised. Systematic sterilisation is a frequent source of scurvy; and if the practice be adopted, anti-scorbutic treatment ought always to be carried on concurrently with the feeding. Sterilised milk often disagrees; it will also keep indefinitely, and stale milk is distinctly bad for the child. If sterilisation is to be done, it should be done twice a day. Exceptionally, during the hot summer weather, for instance, the advantages outweigh the disadvantages; but obviously sterilising is tackling the pure milk problem at the wrong end.

I have found but little, if any, advantage in barley water over plain water. It also should be made twice a day, as it goes sour even quicker than milk. It is not a food for young children, and, as often given to supplement the breast, it is practically starvation diet.

Cream and whey mixtures, though theoretically the soundest, are the most difficult to prepare satisfactorily outside the laboratory. Consequently, I reserve them entirely for the first week, for cases—and they are really comparatively few—in which a fair trial of the milk and water proves a failure, and for periods when the stomach is temporarily upset from one cause or another.

THE PATHOLOGY OF

CONGENITAL HYPERTROPHY OF THE PYLORUS

IN RELATION TO TREATMENT (a).

By EDMUND CAUTLEY, M.D., Cantab, F.R.C.P. Lond.,

Physician to the Belgrave Hospital for Children, and to the Metropolitan Hospital.

Accepting the view that there is such an affection as pyloric spasm, and that the action of the pylorus is that of the closed door which only opens in response to duodenal stimuli, the author argued that there is no evidence that spasm could cause hypertrophy. Almost all physicians had found anti-spasmodic drugs of no value in treating pyloric hypertrophy, a remarkable fact if the symptoms were due to spasms grafted on, or causing hypertrophy. Moreover, spasm might occur at any age, and yet these cases of hypertrophy were peculiar to the first few months of life, and there was no evidence of spasm at a later age causing hypertrophy. Recovery from pyloric spasm under medical treatment in cases mistaken for true hypertrophy had led to an unduly favourable estimate of the value of medical treatment in treating hypertrophy. The latter affection varied from a degree of hyperplasia, which was fatal unless treated surgically, down to a slight hyperplasia, which was compatible with life if no secondary affections occurred. These affections, viz., dilatation of the stomach, gastric catarrh, and occasionally acute oedema of the pyloric mucosa, were due to contraction of the muscle. In mild cases the degree of contraction might prevent sufficient nutritive food passing through the pylorus, and yet not set up the secondary symptoms. Three of his cases had been of this type, and under medical treatment had succumbed to marasmus, although food was present in the intestine after death. It was these cases in particular that made one critical of the assumed value of diet and lavage. Drugs he had found useless. A diet of whey or albumen water, carefully regulated, would suit such cases for a time, but as soon as the strength of the food was increased, secondary symptoms arose. On the assumption that the condition was produced by hyperchlorhydria, cases had been treated by undiluted cow's milk. Such a food had proved useless in his hands, and he suspected that the successful cases were due to pyloric spasm. Recent observations by Miller and Wilcox supported the view that there is no excess of acid in these cases, and all clinical and pathological evidence was in favour of the weak nutritive fluid rather than undiluted milk. Lavage would be useful in hyperchlorhydria and pyloric spasm, but it would hardly be expected to be of value in cases of mild hypertrophy without secondary symptoms. It seemed unnecessary if food were passing through the pylorus, if vomiting was absent, and if there was little or no dilatation. There were undoubted cases of this type. It was of great value in curing secondary dilatation and gastritis, but it only cured these secondary affections, and not the hypertrophy, and might place the child in the *statu quo ante*. Then, if the degree of hypertrophy and contraction was compatible with life, the child might recover. He regarded it of vital importance to differentiate spasm from hypertrophy, and that the medical treatment of true hypertrophy should not be unduly prolonged, for the greater the degree of marasmus previous to operation, the smaller is the chance of the child's recovery.

CLINICAL RECORDS

OPTIC NEURITIS IN CEREBRAL TUMOURS

By L. PATON, M.B.Cantab., F.R.C.S.

This paper is based on the records of 252 consecutive cases seen at the National Hospital, Queen Square. In 202 of those the localisation of the intracranial tumour was definite, and 148 were confirmed by operation or post-mortem. Of the 202 cases, 38, or 18.8 per cent., had no neuritis, 12 had only very slight neuritis, the edges being at no period completely blurred, 27 were in a condition of post-neuritic atrophy when first seen, and the remaining 125 had marked neuritis. Mr. Paton pointed out that the great majority of cases without neuritis occurred in subcortical and pontine tumours. The percentage of cases with no neuritis in tumours of those two areas was, respectively, 38 per cent. and 43.5 per cent. He pointed out, further, that when sub-cortical tumours developed optic neuritis, it almost invariably indicated that the growth had involved either the grey matter of the cortex or the grey matter of the base, and that when pontine tumours developed optic neuritis, it practically, without exception, indicated very definite involvement of the cerebellum. He showed that in tumours of the cerebral cortex the intensity of the neuritis seemed to vary inversely with the distance of the tumour from the anterior pole of the middle fossa. He adduced evidence to show that the nature of the growth had little, if any, influence on the development of optic neuritis, except in so far as the nature of the growth might influence its position. He stated that the figures showed that very little reliance could be placed on differences in the intensity of the neuritis as indicating the side of the tumour, and that in the cases of frontal and of cerebellar tumour neuritis was just as frequently most marked in the optic disc of the opposite eye as it was in the eye on the side of the tumour. The neuritis commenced more frequently in the eye on the side of the tumour than in the opposite eye, but even here the preponderance—23 to 13—was not sufficiently marked to make the sign one of much value for localising purposes. He described in detail the development of the macular changes seen in intense cases of tumour neuritis, and showed that these changes were most probably produced by an overflow of œdematous fluid from the much swollen disc into the nerve fibre layer, and that the presence of very

---

(a) Abstract of Paper read before the Society for the Study of Disease in Children, Jan. 17th, 1908.

well marked macular fans was compatible with the retention of perfectly good vision. The causation of the temporary attacks of blindness, lasting from a few seconds to half an hour, was discussed, and it was shown that these were probably not associated with optic neuritis, as they had been observed three times in cases when no optic neuritis developed, and in other cases these fleeting amblyopias had occurred before ophthalmoscopic evidences of disc change were present. It was suggested that these attacks were due to sudden rises in intraventricular tension, causing a bulging of the thin floor of the third ventricle, and to direct pressure on the chiasma. The attacks were invariably accompanied by increased headache and giddiness. He pointed out that there was no evidence in favour of optic neuritis in these cases being due to an inflammation descending from the basal meninges, nor was there evidence in favour of its being due to pressure of fluid in the vaginal space. The clinical evidence against it being a descending inflammation in the nerve trunks was even stronger, nor was there any more evidence in favour of the neuritis being produced locally by the action of toxins, or of its being a vaso-motor phenomenon. He regarded our knowledge as, as yet, insufficient to justify any definite theory as to the causation of optic neuritis, but a general review of the subject in its clinical aspects inclined him to the view that in so-called optic neuritis there was simply a manifestation locally of a general œdema of the cerebral tissues, due to the irritation set up by the tumour as an actively-growing foreign body.

OPERATING THEATRES.

GREAT NORTHERN CENTRAL HOSPITAL.

Pyonephrosis, with Displaced Heart.—**Mr. Arthur Edmunds** operated on a woman, æt. about 45, who had been suffering from a lump in the left side of the abdomen. This had not caused any very marked symptoms, and although the swelling had been diagnosed as an enlarged kidney, and the patient had been advised to submit to operation, she had refused all treatment. For a short time, however, before her admission to the hospital, the tumour had begun to cause a considerable amount of cardiac disturbance, the heart being displaced upwards and slightly to the left. On admission, the patient was in a critical condition; the abdomen was greatly distended, and was dull all over the left side, the boundary of the tumour passing beyond the middle line. The apex beat was in the third intercostal space slightly outside the nipple line; the pulse was small, rapid, and intermittent; there was marked dyspnœa; the urine contained pus in microscopic quantities only. It was obvious that there was a large cystic swelling on the left side of the abdomen which from its position behind the colon was probably the kidney. An attempt at a radical operation was clearly out of the question. Accordingly, the patient was anæsthetised, the tumour exposed through the ordinary lumbar kidney incision. An incision was then made into the organ, and several pints of pus evacuated. Large drainage tubes were fixed in position, and the patient returned to the ward. Mr. Edmunds said this method of opening such large swellings was, on the whole preferable to tapping with a trochar. It can be performed rapidly, with but little shock, and enables the surgeon to get some idea of the existing condition of the deeper structures. Care must, however, be taken not to allow the fluid to escape too rapidly, as this is liable to produce a fatal dilatation of the heart. The patient bore the operation well, but it was some time before her heart regained its balance, and it seemed safe to proceed to further treatment. All this time the pus had been pouring freely from the wound, but there had been no spreading infection of the surrounding cellular tissue.

The wound previously made was now opened up and extended in both directions. The whole kidney was then excised. This was extremely difficult, as there were dense adhesions in all directions, and it was impossible to avoid opening the peritoneum widely. The vessels were secured without difficulty, however, and the ureter was found normal. The whole wound was packed, the packing being subsequently replaced by drainage tubes. Mr. Edmunds said the case was obviously one of an infected hydronephrosis of a non-calculous character, the obstruction being due to a malposition of the ureter at its junction with the pelvis of the kidney. It would, of course, have been preferable to have excised the whole tumour at the first operation, but the patient's condition was such as to entirely preclude such a procedure. The healing was slow, but the patient made an excellent recovery.

TRANSACTIONS OF SOCIETIES.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

Meeting held Friday, January 17th, 1908.

Mr. Sydney Stephenson, F.R.C.S., in the Chair.

Dr. Edmund Cautley read a paper on the

PATHOLOGY OF CONGENITAL HYPERTROPHY OF THE PYLORUS IN RELATION TO TREATMENT,

an abstract of which will be found on page 153.

Dr. G. Carpenter read notes of a case of

CONGENITAL HYPERTROPHIC STENOSIS OF THE PYLORUS,

which he had treated in conjunction with Dr. D. J. Munro, of Brixton, and which had recovered under medical treatment; diet, lavage and drugs being the methods employed. The infant was two months old. It was breast-fed, and in good health for the first week, but, the bottle being substituted, it gradually lost ground, and, as the parents said, "in spite of being fed on a variety of foods, it was sick after everything." At the time Dr. Carpenter saw it, the infant vomited accumulated feeds, it was constipated, and was passing scanty and concentrated urine. It was wasted, and so weak and ill from starvation that it was thought it would not live through the night. The diagnosis was confirmed by the detection of the typical pyloric tumour as large as an almond and as hard as gristle. There was associated gastric peristalsis in the direction of the tumour. Owing to the infant's condition, operative treatment was considered out of the question. It was ordered 2-oz. feeds of whey every two hours, drop doses of laudanum every four hours, and gastric lavage. This was on May 22nd, and on the following day the opium was reduced by half because of somnolence, and was finally discontinued on June 6th. During the treatment an attack of œdema, associated with albuminuria, difficulty of breathing, and also swallowing, came on. He coughed at his feeds, had to be propped up with pillows, and often had to be held up by his feet, as he choked and went black in the face. The infant weighed 7 lbs. at birth, 5 lbs. 13 ozs. on May 22nd, and on June 14th 5 lbs. 7 ozs. On June 7th humanoid milk was given (2-oz. feeds), and on the 14th milk 1 part and water 2 parts (2 to 3-oz. feeds) was substituted. Lavage was discontinued on June 20th. During the first week of milk and water diet it lost 5¼ ozs. in weight, but after that it began to forge ahead and gained on an average an ounce a day. It vomited for the last time on June 28th. Day by day it took increasing quantities of milk and water, rising from 18 ozs. daily to 30 ozs. on July 6th. While on whey the bowels were open once daily, and the motions were green, but after it had been on milk and water for a week, the stools became quite natural, and numbered 2—4 in the 24 hours. At 7½ months old, the middle of October, he weighed 16 lbs., and was a normal baby, and he is still (January, 1908) doing well. Dr. Carpenter laid great stress on discovering the pyloric tumour, as, without detecting it, it was impossible to be sure that the case was an example of hypertrophic pyloric stenosis. For pyloric spasm and infantile dyspepsia produced symptoms which could not be distinguished from the state in question. Vomiting of accumulated feeds, projectile vomiting, gastric peristalsis, constipation, and scanty urine could all be present without any tumour to account for them. He said that it was necessary to detect the tumour to prevent the mistake of operating upon cases where no tumour existed. He claimed that hypertrophic stenosis of the pylorus was a congenital condition, an abnormality of development and not a secondary muscular affection, the result of spasm, as claimed by Heubner and others. He said that in the cases he had examined microscopically not only was the pylorus muscle hypertrophied, but the stomach muscle also, usually about the pyloric third or fourth. Sometimes all the stomach muscle was hypertrophied, but in that case also the brunt of the enlargement fell on the pyloric end. The musculature of the pylorus was an exaggerated condition of the normal, in which the circular fibres greatly preponderated. He thought that the occlusion of the pylorus might be due to reflex spasm, or, as he would suggest, in some cases to œdema or congestion of the mucous membrane, analogous to the congestive stricture of the urethra. But whatever the explanation of the obstruction of the pyloric channel might be, he considered that dyspepsia was at the root of the illness. Cure the dyspepsia, or, better, avoid the dyspepsia, and the pyloric tumour could be very well left alone. He thought the secret of successful treatment lay, as in all infantile dyspepsias, in the discovery of what form of cow's milk (in the absence of suitable suckling) was least obnoxious to the infant's stomach. Feeds should be small, given regularly, and, above all things, the milk should be clean and fresh. In addition to this, gastric lavage was a well-tried and efficient remedy. Antispasmodic drugs could be used, but they did not appear to do much good. He thought that even the most hopeless-looking cases should not be abandoned by the physician, but submitted to dietetic treatment, and to those drug remedies which had proved beneficial in dyspepsia. As the result of medical treatment, he thought that in the future there would be more medical successes and fewer surgical failures. He thought that if the surgeon were called in, it should be late and not early. What the remote future had in store for the cases cured by the physician time would tell, but Seefisch had reported three cases that had to be operated upon before they were twelve years old, so it was possible that the visit to the surgeon would be merely postponed. If that were so, it was then even better for the child, as the mortality of the operation would be greatly reduced.

In the discussion following the reading of these papers,

Dr. **Sutherland** protested against the assumption that if pyloric stenosis were cured medically, it must have been in such a mild form that it would have recovered without treatment. Operation was a very serious matter, and many infants who had stood the operation died afterwards from bowel trouble of some sort. He did not think that, for a complete diagnosis, one should be able to feel a pyloric tumour, as the pylorus was a very uncertain thing to feel in an infant. The diagnosis could be made if vomiting, constipation, wasting, and marked visible peristalsis were present. Where trouble arose when breast milk was given, the fault was not with the milk, but with the manner of feeding. Small feeds of the most digestible material were required, and if there was a residue of food left in the stomach after washing out for a day or two, the infant was not having suitable food.

Mr. **Lockhart Mummery** said that it was scarcely possible to have a more unsuitable subject for a severe operation. The child was very young and badly nourished, and had probably been vomiting all the nourishment given to it for some days before. Very few cases died on the table. The only patients in which the prospect of operation was good were those seen early before there had been wasting, and in whom there was a fair amount of fat.

Dr. **Charles W. Chapman** said that in the condition under discussion there was a great deal of irritation causing the closure, and he was therefore surprised that no one suggested the administration of carbonate of bismuth. It might be given freely in as much as teaspoonful doses.

Mr. **Hugh Lett** said the members were much indebted to the readers of the papers, as the subject was one of great importance. Surgical treatment was a very serious matter, and in many cases, by the time that the surgeon was called in, the condition was practically hopeless. The physician should be clear at the beginning of his treatment how long he would continue medical measures, lest by unduly prolonging them the prospects of operation were affected. He advocated the claims of gastro-enterostomy as being simpler than pyloroplasty, and safer than Loreta's operation.

Dr. **Reginald Miller** suggested that the symptoms of pyloric stenosis were entirely referable to spasm. First, because of the onset of the disease. At the Clinical Society last year, 40 cases were collected, and in 70 per cent. of them the onset did not occur until the third or fourth week of life. He had a case in which diarrhœa preceded the onset of the symptoms. It was true that many babies vomited from birth, but not sufficiently to cause wasting, and the well-marked constipation was frequently absent during the first two or three weeks of life. That suggested that there was not marked blocking at the pylorus as a congenital lesion. Secondly, only the circular coat was hypertrophied, and he agreed that if it were spasm, the longitudinal coat would be hypertrophied. But if the longitudinal coat were hypertrophied, presumably there would be no symptoms. Thirdly, that although the baby did not live, yet as the result of lavage and careful dieting, it usually died of diarrhœa, showing that the pylorus was once again patent, and that something had happened, for presumably the spasm had been relaxed. A fourth and controversial point was that a few cases got well in which gastric peristalsis was observed week after week, and in which the tumour might be palpable for weeks. Such cases strongly simulated the real condition which Dr. Cautley referred to, and he, Dr. Miller, thought they were quite identical.

Dr. **T. R. Whipham** showed a case of congenital heart disease in a girl of 17. There was no cyanosis or clubbing. There was a history of slight rheumatism in the feet three years previously, but none of rheumatic fever or chorea. The left ventricle was greatly hypertrophied, and over the upper part of the sternum there was a marked thrill. In this region, and to the right, a loud systolic murmur was audible which could be heard all over the præcordium. There was no polycythæmia. The diagnosis was some malformation of the great vessels, possibly a patent ductus arteriosus.

A case of syphilitic synovitis of the knee-joint in a boy, æt. 7, was shown by Dr. **Porter Parkinson**. He was the subject of congenital syphilis, and the effusion followed periostitis of both tibiæ. There was marked effusion, but no pain or tenderness, and no alteration in the bony structure of the joint.

Dr. **Parkes Weber** said he believed that in syphilitic joint diseases the Röntgen rays were of great use in diagnosis.

Dr. **Sutherland** said it was contrary to his experience to find rapid improvement under mercurial treatment. In his experience fluid came and went, and recurrences were very common. He had seen cases which had been operated upon, and yet the condition recurred.

Mr. **Hugh Lett** considered it a typical case of synovitis of the knee due to inherited syphilis, and he thought these cases were important, as they were occasionally diagnosed as being due to some other cause. He had seen several cases which had been treated with splinting for some time in consequence of a diagnosis of traumatic synovitis having been made. In another important variety of the congenital syphilitic joint there was considerable thickening of the synovial membrane, with little or no effusion into the joint. Both these types—viz., with or without effusion—were occasionally treated as tuberculous joints. The most striking feature in these cases was the absence of pain on movement.

The **Chairman** said he thought the way mercury was used had something to do with the result. Some of the syphilitic joints associated with interstitial keratitis yielded to intra-muscular injection of mercury.

Dr. **Porter Parkinson**, in reply, said there was evidence of thickening in the tibiæ due to periostitis. The effusion in the knee-joint appeared while the child was under mercurial treatment for periostitis of the tibia. Whilst Scott's dressing was beneficial, he thought it was due to the pressure exerted. In most of such cases he did not think there could be much difficulty in the diagnosis, but he had recently read a paper contributed to a French journal stating many mistakes had occurred between that condition and tubercular joint disease.

Dr. G. A. **Sutherland** showed a case of cretinism in a boy, æt. 9, who was seen in November with typical signs of cretinism present. He improved very markedly under thyroid treatment. Growth in the long bones was very delayed, and pituitary extract had been given without any benefit so far. He asked if any member had seen any improvement from pituitary extract in a similar condition.

Dr. **Parkes Weber** said he had never seen any improvement of any condition from pituitary treatment. He had never used it himself.

Dr. G. A. **Sutherland** also showed a case of tubercular peritonitis in a girl, æt. 9. When first seen in September the case seemed hopeless; there had been signs of tubercular peritonitis for five months. She was wasted, and in a stuporous condition. She suffered from diarrhœa, and had delirium at night, and hallucinations during the day. She is now convalescent, and the signs of active tuberculosis have subsided, although the abdomen is still distended.

Dr. **Cautley** agreed that the prognosis in uncomplicated tubercular peritonitis was eminently favourable if there were no tubercular masses and no purulent effusion. When patients died, it was found that they had secondary complications, such as tuberculous disease in the lungs.

Dr. **Carpenter** said tubercular peritonitis seemed to be the least fatal of tubercular affections, but in many of the cases there was meningitis, and in some the lungs were affected later. He had followed up a large number of cases of tubercular peritonitis, and had been surprised at the large number who had subsequently died.

Dr. **Sutherland** agreed that many such cases died, and that they did so from some such complications as had been mentioned. When gradual improvement was noticed in this child, he put her on a proteid and non-fermentative diet, and under that the condition improved rapidly, and the abdominal distension subsided. The combination of open-air treatment and diet brought about the cure. Drugs had no part in it.

Dr. **McMaster** (for Dr. Guthrie) showed a case of acute polio-encephalitis following measles. The patient, a girl, æt. 5, was well nourished and intelligent, but had spastic diplegia. There were no ocular symptoms; there was weakness of the muscles of the back, so that she could not sit upright and could not hold her head up. The condition simulated one of congenital spastic diplegia.

Mr. P. **Lockhart Mummery** showed a case of supernumerary auricles in a boy of three months. On each side of the head there was a supernumerary auricle situated just in front of the external auditory meatus. On the right side it was about half the size of the normal ear; on the left side it was much smaller. There were no other congenital defects.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD THURSDAY, JANUARY 30TH, 1908.

The President, Mr. R. **Marcus Gunn**, F.R.C.S., in the Chair.

THE following card specimens were shown:—

Mr. E. E. Henderson: Sections from case of Sarcoma developing under Calcareous Plate.

Mr. P. C. Bardsley: A New Form of Scotometer.

Mr. S. Stephenson: A case of Buphthalmia apparently cured by the performance of Iridectomy.

Dr. L. Guthrie and Mr. S. Mayou: Right Hemiplegia with Obstruction (? thrombosis) of the Left Common Carotid and Central Artery of the Retina, with Perception of Light in the Eye.

Mr. G. H. Goldsmith: Optic Neuritis.

Mr. J. S. Horsford: Essential Shrinking of the Conjunctiva.

Mr. C. Wray: Sympathetic Iridocyclitis.

PAPERS.

Mr. S. **Mayou**: Microphthalmia, resembling Glioma, with Lenticonus and Hypertrophy of the Ciliary Body.

Mr. Mayou said the case belonged to the class of phthisis bulbi. Some of those cases had been of inflammatory origin, but this, and possibly some of the other cases, were attributable to the imperfect development of the mesoblast, and it entering the ocular cleft to form the vitreous. The child was 6 months old, and was admitted under Mr. Hancock. The mother had noticed that the left eye was very small from birth, but the child had no other deformities. There were no signs or history pointing to congenital syphilis. The right eye was normal in size, and there was nothing abnormal in the fundus. In the other eye there was a well marked pupillary membrane. Behind the lens, which was clear, was a yellowish-white reflex, with vessels on it, similar to that seen in glioma and pseudo-glioma. As diagnosis was doubtful, enucleation was performed, and the child made a good recovery. The eye was hardened in formal, and sections cut antero-posteriorly. The optic nerve was removed, and cut in transverse section. The globe measured 15 m.m. antero-posteriorly, 10 vertically, and 10 horizontally. The sclera showed no change. The angles of the anterior chamber were imperfectly formed, owing to incomplete separation of the iris from the back of the cornea. The ciliary body was free from signs of inflammation. Behind, and lying on the pars plana was a large mass of pigmented and unpigmented cells, derived from the ciliary body. Towards the outer part was an attempt at alveolar formation. The retina was detached, but did not stop at the ora serrata, but passed close behind the ciliary process, where it was continuous with the anterior layers of the epithelial cells and the mass mentioned. The lens was thickened and thrown into folds, and consisted principally of neuroglial tissue, but possessed no regular structure. The retinal detachment was of earlier date than the hæmorrhage. The choroid presented a coloboma below, but the blood vessels were not thickened. The lens showed a condition of posterior lenticonus. The central artery was well developed, and showed no changes in its walls. Generally in such cases the distortion of the posterior part of the lens was associated with a persistent hyaloid artery, or a gap in the posterior part of the lens capsule, but neither of those conditions was present in this case. There was a hypertrophy of pigmented and non-pigmented epithelial cells, the reason of which it was difficult to understand, unless it was due to nutritional disturbance in the line of separation of the two layers in the primary optic vesicle.

Mr. L. **Paton** read a paper on OPTIC NEURITIS IN CEREBRAL TUMOURS, an abstract of which will be found under the head of "Clinical Records."

The following two papers by Mr. Simeon Snell were, in his absence, taken as read: Carcinoma of Orbit originating in a Meibomian Gland.

The case occurred in a woman, æt. 63. In 1904 another surgeon had removed a lump from the right upper eyelid. In July, 1905, there had been a recurrence at the site of that scar reaching back to the orbit, and about the size of a walnut. This was removed with the portion of eyelid, but in June, 1906, there was another recurrence, and then the eyeball was removed and the whole orbit cleared out, and chloride of zinc paste applied. Still further recurrence had occurred, and the orbit was filled with a large ulcerated growth, and the preauricular and cervical glands were enlarged. Dr. A. E. Barnes reported that it was a spheroidal-celled carcinoma, and was of opinion that it had probably originated in a meibomian gland. Mr. Treacher Collins corroborated this.

The second paper was on Coloboma of Iris in each

Eye, occurring in five generations. Mr. H. was the first person seen, and he had a large coloboma in each eye, down and out. The defect was known to have existed in his grandmother, in her sister, and in his mother. Mr. H. had six children, three of whom were affected, and of these, two had children—one three children of which two were affected, and one one child affected. Mr. H. was the only child of his father, but his mother had, by a second husband, five children of which three were affected. One of these had three children, two of whom were affected. The other had one child, which was not affected. In all, of 41 persons, 12 are affected—five males, seven females. In the great-great-grandchildren, the defect was complete aniridia.

HARVEIAN SOCIETY OF LONDON.

Meeting held Thursday, January 23rd, 1908.

Dr. G. A. Sutherland in the Chair.

The evening was devoted to the showing of
CLINICAL CASES AND PATHOLOGICAL SPECIMENS.

Dr. Sidney Phillips showed: (1) A case of splenic anæmia in a child. The liver, spleen, and lymphatic glands were enlarged, and the blood showed the usual signs of anæmia, but no leucocytosis. The case was discussed by Dr. Sutherland. (2) A case of Landry's paralysis in which recovery had taken place.

Mr. Clayton-Greene showed: (1) A case in which rupture of the liver had occurred from abdominal injury. An operation was performed within seven hours of the accident, and recovery followed. (2) A specimen of cirsoid aneurysm of the arm and forearm. The arm had been amputated owing to the extensive involvement of the vessels. This was discussed by Dr. Low.

Dr. Willcox showed: (1) A case of greatly enlarged lymphatic glands on both sides of the neck, which he regarded as due to lymphadenoma with tubercular infection superadded, the latter having been proved by investigations of the opsonic index. The case was discussed by Dr. Sutherland. (2) A case of enlarged liver and spleen, with leucoderma. This was regarded as cirrhosis of the liver. Dr. Langmead discussed the case.

Dr. Langmead showed a case of third nerve paralysis, which was discussed by Dr. Sutherland.

Dr. Carmalt Jones showed a case of arterio-sclerosis, with a vascular lesion, giving rise to a crossed sensory lesion.

Mr. W. V. Low showed a case of Charcot's disease of the knee-joint, with spontaneous fracture of the tibia on the same side. There were well-marked signs of tabes dorsalis.

Mr. Crisp English showed: (1) A case of Charcot's disease of the ankle-joint, which was discussed by Mr. Kelly. (2) A specimen of large fibroma of the breast.

Mr. Lawrence Jones described: (1) A case of musculo-spiral paralysis. (2) A specimen of ureteric calculus.

Mr. Maynard Smith showed a case of injury to the brachial plexus, followed by a root paralysis, which recovered after operation. The case was discussed by Dr. Willcox.

Mr. E. Morris showed a skiagram of a supernumerary thumb.

Dr. C. Singer described the drawings, microscopical and pathological specimens, of a case of exophthalmic goitre which had recently been under his care.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

Meeting held Friday, January 31st, 1908.

The President, Dr. Walker Downie, in the Chair.

Before proceeding with the business of the evening Dr. Walter Downie made sympathetic reference to the sudden death of Professor Sir Thomas McCall Anderson, who became a member of this Society in 1861, and held office in it both as President and Vice-president.

Dr. Albert A. Gray read notes on a case of abscess of the temporo-sphenoidal lobe of the brain, with rupture into the lateral ventricle. He described the condition of the patient—(a girl, aged 7 years)—before she was operated on; the operation, and the condition of the patient for 14 days after the operation till death occurred. He also read the notes of the post-mortem examination, and showed specimens of the temporal bone and the brain of the case, illustrating the pathological conditions that gave rise to the symptoms and caused death.

The chief interest in this case was the length of time the patient lived after the rupture of a cerebral abscess into the lateral ventricle of the brain; the temporary improvement in the general condition that resulted from the operation which effected the evacuation of the purulent contents of the lateral ventricle.

The abscess was due to chronic middle ear disease, and acute symptoms had existed for three weeks before admission to the hospital. Three days previously the symptoms increased, paralysis of the face came on, and the patient was almost comatose, only uttering a querulous cry when roused. The radical mastoid operation was at once performed, but no abscess was found nor any opening leading to the brain. The lateral ventricle got tapped in the course of the operation, and a large quantity of watery pus gushed out. The wound was dressed in the ordinary way. The patient's condition improved immediately after the operation. On the second day coma had passed off, and by the fourth day the facial paralysis had disappeared. The neutral condition was quite normal, and the patient answered questions intelligently. On the tenth day the patient became apathetic and did not care for food, then twitching of the hands began, and on the fourteenth day after the operation death occurred from meningitis.

In cases where cerebral abscess ruptures into the lateral ventricle death generally follows in twelve to twenty-four hours. Here there was a temporary recovery after the pus was evacuated from the lateral ventricle, which was no doubt due to the relief of the intracranial pressure. In the discussion which followed it was suggested that it might be possible to save the patient's life in such cases by draining thoroughly the lateral ventricle as well as the operation wound. This it was pointed out might prevent the spread of infective material to the lateral ventricle of the opposite side, to the third ventricle and to the fourth ventricle which in this case had taken place, and which set up the septic basal meningitis that lead to the death of the patient after the symptoms due to the abscess itself had disappeared.

Dr. Kelly read a short paper written by Mr. Freeland Fergus, the subject of which was "Lachrymation." The various causes, and the treatment of this condition were indicated, and a short discussion followed.

CORRESPONDENCE

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Feb. 2nd, 1908.

Hæmophilia.

Histological study has been found incapable of explaining the cause of hæmophilia. Chemical examination of the blood, however, has thrown some light on it. It is admitted to-day that the affection is connected with some trouble of coagulation produced by imperfection of the ferments of the blood, which is proved by the fact that a cure can be obtained by injecting fresh serum which contains the ferments of the blood. Such is the conclusion formulated by Dr. L'Abbé at the Medical Congress held last October, and that this bad quality of the blood ferments is due to deranged functions of certain organs (liver, suprarenal capsules, thymus, thyroid ovaries), or from other undetermined causes.

However, what is necessary to know is the method of curing the disease.

The ordinary methods fail in general. Perchloride or iron, antipyrin, ergotin, have been employed without much effect. According to Sahli, adrenalin was successful in some cases, and L'Abbé obtained a cure by the injection of half a milligram of adrenalin. As a local application—bleeding gums, vegetations—it has also produced good results.

Subcutaneous injections of gelatine in artificial serum (1—5 per cent.) at the dose of from 1 to 3 ozs., did not deserve the success attributed to them.

Chloride of calcium plays, as everyone knows, an important *rôle* in the coagulation of the blood. The application of a solution of chloride of calcium (1—100) on a bleeding surface favours coagulation and arrests the hæmorrhage. Taken internally, the salt exercises a hæmostatic action, both preventive and curative, on the condition that its use is prolonged. Lactate of calcium is superior to the chloride, according to Paramore and Wright, which, however, L'Abbé contests. For him the salts of calcium taken internally possess a very problematic hæmostatic action.

Of all the methods of treatment, the most active is the intra-venous injection of half an ounce of fresh serum; immediately the hæmorrhage ceases, and an operation can be undertaken without danger. At the end of a few weeks the effect is spent, and the injection must be repeated. The remedy has also been employed with success subcutaneously; practitioners who might hesitate to inject the serum into the vein can always employ the more simple method.

The fresh serum should not date over 15 days. The serum of the horse, the rabbit, or of man may be employed, and, in the absence of these, anti-diphtheritic serum might be used.

The hygienic treatment should not be neglected—sea or mountain air, tonics, cacodylate of soda, discodide, methylaisinate, etc.

Treatment of Polyuria.

Intense polyuria constitutes frequently a very grave affection. It brings about rapidly a state of emaciation which terminates in cachexia; it is accompanied by frequent desire to urinate, intense thirst, and an exaggeration of the appetite which fatigues the stomach. All these symptoms are especially well marked in polyuria, associated with glycosuria and phosphaturia. Frequently, however, the cause cannot be determined, and the treatment has to be addressed first to modificators of the nervous system, then to those of arterial tension, and finally to derivatives. Amongst the former, valerian, says M. Plicque, takes the first place. It is generally given in the form of extract on account of its disagreeable odour. Twenty grains three times a day is considered a proper dose, although it might be increased.

Antipyrin possesses the double advantage of moderating the spinal irritation and diminishing the urinary secretion. Given in 10-grain doses four or five times a day, or every hour in bad cases, antipyrin succeeds admirably in diminishing the quantity of urine. It should be used, however, with caution in polyuria of renal origin, as it might irritate the kidney. Salicylate of soda may be tried in gouty and rheumatic subjects, but is counter-indicated in albuminuria. It sometimes acts very rapidly.

Belladonna and opium should be employed with much reserve. They are specially indicated in polyuria accompanied by vesical tenesmus, nocturnal incontinence, frequent and painful desire to urinate.

Bromide of potassium is especially useful in polyuria of diabetic patients, and also in that of epileptics.

Iodide of potassium or of sodium give the best results in polyuria due to arterial tension, but their effects require several weeks to become manifest. The doses should not exceed 20 grains per day.

Ergot of rye, or ergotin, has been employed with varying success. Hydrastis and hamamelis are less active, but more easy to moderate in their effects than ergot of rye. The co-existence of hæmaturia would be an indication of their use.

Derivative agents, as purgatives, sudorifics, should be employed only occasionally, and are specially indicated in polyuria of nervous origin.

GERMANY.

Berlin, Feb. 2nd, 1908.

At the Medizinische Gesellschaft, Hr. H. Senator spoke on

Diabetes in Married Couples (Diabetes Conjugalis) and Its Communicability.

He took notice of some earlier statistics regarding the frequency of the occurrence of diabetes in married couples, and which, as a whole, amounted to 1⅓ per cent. This estimate was not correct, as, as H. Leo was the first to point out, it was not determined in the inquiry how many of the diabetics were married, concerning which point, in the case of men, at least, no indication whatever was given. We knew nothing of the period of incubation of the disease, but a minimum of six months had been accepted, when the possibility of transmission had been considered at all.

From observations made in his private practice, the speaker had ascertained that, amongst 516 diabetics who were married, there were 21 married couples, of which, however, 3 were almost simultaneously attacked; 18 cases, therefore, remained to be considered—3.5 per cent. If those cases were deducted that had been married barely a year, the percentage was higher—viz., 4 per cent., a percentage that gave food for thought. In four of the diabetic couples there was a hereditary tendency on both sides, so they must be left out in considering the question.

The speaker then quoted a number of statements from the literature of the subject that appeared to be in favour of the transmission of the disease, and related himself the case of a medical man practising in a small town of 2,500 inhabitants: in one street of this town there were six diabetics, and a case was known to him in which the second wife of a diabetic, whose first wife died of the disease, also fell a victim to it.

There were also experimental observations in which a dog into whose intestinal tract intestinal contents of a diabetic patient were introduced, excreted sugar; there was also the case of guinea-pigs who excreted sugar after subcutaneous injection, but this had not been confirmed from other sources.

He asked practising physicians to contribute to the solution of this question. It was only by the family doctors working together that it could be solved, as they only were in a position to take note of all the conditions.

Hr. Neumann had instituted an inquiry in Potsdam through the medical men and apothecaries there, and could discover nothing that pointed to any infectiousness of diabetes. Private practice alone must not be made use of in the inquiry, but practice amongst paupers as well.

Hr. Albu attributed an important *rôle* to accident, when both husband and wife suffered from such a widespread disease.

Hr. Ewald also doubted the infectiousness of the disease, and considered that the observations that had been made in that direction were not convincing.

Hr. Senator participated in all these doubts, but by bringing the subject forward he hoped to stimulate further inquiry.

In a case of diphtheria bacillus and streptococcus sepsis that recovered (*Deutsche Med. Zeitung*), Dr. Philip Mahler employed injections of serum. On the left thigh into which the injections were made, a cutaneous eruption appeared (a number of circumstances were against it being erysipelas). The writer took it to be a primary necrosis set up by the injections. No similar case had been recorded.

Dr. Ernst Rieben, of Bern (*ibid.*), has been interesting himself with the solubility of pills in the gastro-intestinal tract, his investigations being carried out in the Institute for Medical Chemistry and Pharmacology of that city. Amongst other things, he found that pills coated with silver leaf were not nearly so readily absorbed as pills without that covering.

AUSTRIA.

Vienna, Feb. 2nd, 1908.

Tetanic Deformity.

At the meeting for "Innere Medizin," Lehndorff presented a twelve-year-old boy with great deformity of the spinal column and ribs, the result of a severe attack of tetanus.

About the middle of May he got his ankle injured. In a few days after tonic spasms commenced in the muscles of the body and extremities, with opisthotonos, abdominal muscles as tense as boards, accompanied with spasmodic attacks of dyspnœa. After treatment with serum and chloral, the spasms relaxed, but the deformity of kyphosis in the dorsal vertebræ persisted, while the scapulæ were raised higher and twisted towards the sternum. The ribs at their cartilages were bent inwards, and the thorax quite distorted. All the muscles of the child are well developed and strong, and the electric movement normal. There is no pain in the bones, and the Röntgen rays show a normal structure.

There is no case in the literature of the subject where this distortion of the skeleton is recorded, and no doubt can remain that the deformity was the result of the long-continued contractions and bending of the young structure.

Female Milk with Rennet and Acids.

Brenenfield read a paper on the action of rennet and acid on milk, but more particularly on female milk. The casein of cow's milk was easily acted on by both rennet and acids, but human milk was not curdled by either. If, however, human milk be centrifugalised, and one-tenth of a solution acidified, 2.4 per cent. added, and the whole raised to 40° C., = 104° F., coagulation at once sets in; but if the temperature is raised still higher, the coagulation disappears and no curd is observed. If alkali be added to exactly neutralise the acid, the mixture with the female milk will instantly coagulate. It thus appears to be the acid that produces the curd in human milk and not the rennet.

Escherich said his experience was just the opposite in the treatment of children. If an infant be given rennet after a meal, a fine flocculent clot will be formed in the stomach; if a small quantity of acid be added, the clot is rapidly dissolved, leaving the whole in a fluid condition.

Fränkel thought the casein of human milk could not be the same as that of the cow, because the albuminoid reacted differently, and the quantities were not in the same proportion. With acid in cow's milk, 83 per cent. of the nitrogen will be thrown down, while the same acid will only bring down 16 per cent. of the nitrogen in human milk. No specific rennet action exists, as the rennet from the human stomach will not coagulate the milk from a female. The casein in both differs widely in the amount of phosphorus they contain.

Again, if the filter be made finer with acid in the human milk, and placed in vacuo at 30° Cent., another albuminoid body will come down containing a large quantity of sulphur. This seems to be the body that comes down when the acidity is concentrated in the stomach, forming a flocculent mass.

Iodglidine.

In a lecture by E. Schmid, iodglidine was praised as a new drug of wonderful merit in the treatment of arterio-sclerosis and asthma. The substance is a non-irritant vegetable combination, which he has prescribed for a year now with excellent results. The iodate combination with the vegetable substance makes it easily borne and more readily assimilated than any other preparation on the market. Hitherto the toxic effect of the drug has been a drawback, limiting its use and often disappointing the prescriber owing to cardiac depression, vomiting, etc. The happy combination of vegetable albumin prepared according to Klopfer's idea removes all these disadvantages from the administration of potass iodide, as the iodine is already incorporated with albumin and ready for absorption which hastens its transfusion. Schmid next illustrated his success by reading a few cases which he had treated with the drug.

E. G., æt. 58, a metal worker, well nourished, but pale, with anxious features and pulsus tardus—60 per minute—but regular. Both radial arteries were rigid and serpentine. He frequently complained of pain and pressure in the chest, with great dyspnœa. No trace or history of syphilis was present. After 14 days' administration of two iodglidine pastilles, containing 0.5 gramme each, three times a day, and thus representing 0.3 gramme of the iodate of potassium, or 4.6 grains of the drug, the feeling of pressure, weight, and anxiety quite disappeared. He advised the iodglidine to be suspended for a week to observe the effects. The attacks did not come on at regular intervals as heretofore, but a heavy, uneasy pressure lingered over the chest. Again, the two pastilles of iodglidine were recommended for another 14 days, and this was succeeded by a perfect disappearance of all the uncomfortable feeling and pain. No pressure nor difficulty of breathing is now experienced; neither was any trace of iodism observed during the whole course of treatment.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

The Late Professor Pettigrew, St. Andrews.—The death of Dr. J. Bell Pettigrew was announced on January 30th. He had been in failing health for some years, so that the news was not altogether unexpected. He was born in 1834, and was trained in medicine in Edinburgh, where he graduated after a distinguished course of study. In 1860 he was appointed Croonian Lecturer to the Royal Society, and in 1872 he began to lecture on physiology in Edinburgh. Two years later he was elected to the Chandos Chair of Medicine in the University of St. Andrews, and held that post up to the time of his death. The Chair was converted into a Chair of Physiology by the University Commissioners about ten years ago, in connection with the rearrangement of the teaching consequent upon the amalgamation of the Dundee colleges with St. Andrews University. During the latter years of his professoriate Dr. Pettigrew had withdrawn from active work in the way of lecturing, and filled the leisure he enjoyed by engaging in research. Dr. Pettigrew's early investigations concerned the mechanism of circulation, and he published important papers on "The Muscular Fibres of the Heart" and "The Valves of the Vascular System." He made a hobby of aëronautics, and in 1867 published a memoir on the "Mechanism of Flight." He was also a connoisseur of violins, of which he possessed a remarkably fine collection. His interest in public affairs was not restricted to those of his own profession, for, in addition to being for some years a member of the General Medical Council, he threw himself into municipal politics, and took an active part in promoting local railway enterprise. He is survived by a widow, but no family.

Ruchell Fever Hospital, Glasgow.—The Local Government Board has decided to hold an inquiry into the affairs of this hospital, and has appointed Sheriff Crawford, K.C., assisted by Prof. Harvey Littlejohn and Mr. A. Murray, to investigate and report. It will be remembered that the Local Government Board deputed Professor Littlejohn to make a preliminary inquiry about a fortnight ago, in consequence of complaints made by the resident medical staff.

Morison Lectures on Insanity.—This year's course of lectures was delivered on January 27th, 29th, and 31st, by Dr. Lewis Bruce, Superintendent of Murthly Asylum, in the Royal College of Physicians, Edinburgh. The subject of the lectures was "The Symptoms and Etiology of Mania."

BELFAST.

Public Health.—During the past week there has been a slight but distinct recrudescence of the epidemic of cerebro-spinal meningitis. This epidemic began about a year ago, reached its height last spring, and died down in the autumn, there being only a very few cases reported each month for some months now.

Ten cases were reported last week, and there are at present in the Purdysburn Fever Hospital 19 cases under treatment. There are probably a good many more in the city, as of late the cases have not generally been sent to hospital. The Notification of Births Act comes into force in Belfast this month, and the local executive of the Women's National Health Association have already asked the Superintendent Medical Officer of Health to supply the Association with a list of all births in the city, so that they might render assistance to both mother and baby when needed. As the births number some eleven or twelve thousand annually, the Association will have plenty of work to do.

Belfast Hospital for Sick Children.—The annual meeting of this hospital was held last week, when Mr. T. S. Kirk, F.R.C.S., read the medical staff report. In the intern department last year there were treated 269 medical cases, 361 surgical, and 17 eye cases. The operations numbered 352, and there were 45 deaths. The general report showed an average expenditure upon in-patients of 2s. 4½d. per day, and the annual cost per bed occupied £50 2s. 2d. Among the speakers at the meeting was Dr. P. R. O'Connell, J.P., one of the surgeons to the Mater Hospital, who spoke in a most friendly way of the excellent work done by the medical and surgical staff.

LETTERS TO THE EDITOR.

LAW REFORM AND THE MEDICAL PROFESSION.

To the Editor of The Medical Press and Circular.

Sir,—One is always reluctant to write a word in opposition to a paper which devotes itself to raising the honourable position of medicine. Sometimes, however, a paper, in attempting so great a task, may fall into an error and thus produce the very opposite effect to that intended. In a leader in your issue of the 22nd ult., you say, under "Law Reforms and the Medical Profession":—"Of all the coming reforms, there appears to be no single one of more direct or urgent importance than that which asks for some re-adjustment of the present system, whereby opposing expert evidence is now tendered by both parties in a law-suit. A more costly device for getting at the truth could hardly be imagined than that which brings into court on either side an imposing array of more or less eminent expert witnesses." You then proceed to ask: "Why should not a body of experts be appointed to sit permanently and decide upon all medical points submitted to them for consideration?" The answer to this question of yours is that which you yourself give further on in the same article, when you speak of "the spectacle of half-a-dozen bigwigs in the witness-bog flatly contradicting half-a-dozen colleagues of equal standing." As, since you make no suggestion that the six bigwigs on one side or the other are dishonest when they flatly contradict each other, is there not some other cause beyond partisanship which makes them so widely differ? The answer is that there is another and greater cause, and one which will last for all time, and that cause is summed up in the few words that, the science of medicine being infinite, opinions must differ. Those who are familiar with the discussions of medical societies must recognise the insurmountable difficulties which beset the science of medicine at every turn, and cause the opinions of equally eminent men to be so diametrically opposed. Nowhere, then, is the value of an arbitrator of more advantage to the litigants than in a case where scientific experts honestly disagree. There is no one, in the writer's opinion, more capable of drawing sound deductions from conflicting opinions, and of giving sound advice to a jury, than a High Court Judge, unbiassed and untrammelled by scientific knowledge of medicine, yet having had laid before him, as plainly as possible, the theories of both sides. So much in favour of the present system. Now, against the proposed alteration, no matter how large the number of members of the proposed board, there would still be opposing theories held by its members. Further, a preliminary expert examination, with its attendant likelihood of disagreement, must mean the assemblage of a number of eminent men at an enormous expense to the ratepayers, an expense at present very properly borne by the litigants, or the established board would ere long fall into the usual perfunctory body consisting of only just sufficient in number to constitute a quorum, and composed mostly of the same individual members whose questions, judgments and reports would savour very much of mechanical results. For it must not be overlooked that in all similar bodies, such as committees, etc., there are two or three (sometimes only one) who practically do all the work. Then, again, medicine and surgery have their fashions and cranks, which would not be submitted for the impartial judgment of an outside court. If the question is to be decided by technical experts, what will be the position of the jury, the boast of every Englishman? The tendency of the present day is to make more and more appointments, with the result that the public are gradually losing their individuality, medical men their self-confidence, and the country is overrun by those whose sole aim appears to be to magnify the importance of their individual appointments, increase the scope of their offices, and reduce the science of medicine to something little better than a clerkship.

I am, Sir, yours truly,

R. H. H.

February 1st, 1908.

To the Editor of The Medical Press and Circular.

Sir,—With regard to your leader in The Medical Press and Circular, January 22nd, *re* "Law Reform and the Medical Profession," I should like to ask—Why should not such a course as you propose be taken in all cases of disputed medical evidence in all civil actions, and a report be placed before the Court?

(1) Of facts admitted on both sides.

(2) Statement of differences in opinion, such differences being supported by a statement of the grounds upon which such differences of opinion are based.

(3) A summing-up by the "Official Referee" of the case as a whole, and his opinion of it.

The fees should be paid as "divided costs" between plaintiff and defendant.

I do not know if I make my meaning very clear upon this latter point. What I wish could be avoided is party worship.

Both sides might nominate men in whom they had confidence, but they should not go into the matter in any way tied to support the case of those who nominate them; they should have no reason to feel biassed. The one idea in their minds should be, "What are the facts of the case as they appear to me, and what opinion have I formed from what I regard as established facts, no matter how they may tell for the plaintiff or for the defendant?" The present state of affairs is indeed lamentable, and makes medical evidence a byword and a subject for scoffing with the laity.

Sincerely hoping that some radical reform may be effected at no distant date, and thanking you for having drawn attention to so grave an evil,

I am, Sir, yours truly,

John W. Martin.

Sheffield, January 24th, 1908.

NURSING HOME CHARGES.

To the Editor of The Medical Press and Circular.

Sir,—Although the question I am desirous of raising herein is somewhat outside the scientific field of surgical practice, I trust you will kindly allow me to ventilate it, and afford me, possibly, the authoritative answer I desire.

A relative of mine at present in a private nursing home for a somewhat serious operation to her hand, though well able to walk to the operating theatre, had naturally to be carried back to her room on a stretcher (up a winding staircase) after the anæsthetic. The men who transferred the patient thus are, I may say, permanently employed by the home, performing other duties as well. In her last weekly account, just rendered, appears the item, "Bearers, 4s." This is not a large amount, I know, but is it not somewhat unusual and unreasonable?

In the next place, it has been my experience that the inevitable extras, such as dressings, visitors' teas, etc., are invariably left to the end, when they cannot easily be checked. Is there sufficient justification for this?

I readily admit that there may be cases where neither the patient nor relatives would care to be worried while the former is in a critical condition.

I am, Sir, yours truly

Lux.

TREATMENT OF CORNS IN THE ARMY.

To the Editor of The Medical Press and Circular.

Sir,—I am glad to learn from your last issue that the treatment of corns is to be carried out in the Army.

It is little known what intense suffering is caused by corns among working people and soldiers whose boots come out of a ready-made stock—indeed, not these alone, but vast numbers of well-to-do people are "voluntary" sufferers from corns, inasmuch as they are slaves to a fashion of tight, and pointed, and high-heeled boots.

On one occasion, after amputating a leg, necessitated by a compound fracture, the first words of the patient on recovering from the chloroform were, "Which leg, sir, have you cut off?" I informed him that it was the right leg, and his reply was, "Thank God, my corns are gone." I examined the foot, and certainly there was cause for his thankfulness—five or six corns on the sole of the foot, some of them nearly an inch across. This poor fellow said he "sweated with pain from morn till night."

Well, corns don't kill people, but they are the cause of a life-long suffering, and as medical men don't give much consideration to them, it is not surprising that people place themselves under the care of corn-cutters, some of whom become corn quacks and extortioners.

Well, the treatment of corns is not *corn cutting*, but eradication, and if the operation is limited to corn cutting, it had better be avoided altogether. Corn eradication is an operation in which selected members of the Medical Staff Corps, who in intelligence are the pick of the private soldier, could very soon become skilled. For the operation the instruments required are a sharp dissecting knife, a sharp and pointed pair of small scissors, and sharp-pointed forceps. The foot should be soaked in warm water for half an hour, or, in cases of very large corns on the sole of the foot, for an hour; then the delineation between the corn and healthy tissue becomes clear. The edge of the corn is to be lifted with the forceps, and the knife or scissors delicately used to sever the connection of the corn with the healthy tissue. The cutting should be rather towards the corn than towards the healthy tissue, and under no circumstances should there be any bleeding whatever. If there should be bleeding, it is better to desist and do the operation another day, and with greater care.

A corn once removed in this manner may never recur. Any sign of recurrence should be quickly removed, and I distinctly assert corns are curable by this operation.

I do not know the name of the Army surgeon who has suggested that the treatment of corns should be taken up by the bearer companies, but certainly the suggestion is worthy of great praise.

Further, I am inclined to suggest that if practical instruction in the treatment of corns, such as I have described, were given in ambulance lectures, much agony among the poor might be prevented.

I am, Sir, yours truly,

A. T. Norton.

MOTOR-CARS FOR MEDICAL MEN.

To the Editor of The Medical Press and Circular.

Sir,—In reply to a letter from "M.D." on the subject of a small motor-car suitable for a country practitioner, it is very difficult to answer the first part of his letter. The broad lines of selection may be stated thus:—

A car by a well-known manufacturer, with an agent, who knows something about it, not too far off—*i.e.*, in Dublin (I am writing in Ireland), short-wheel base in any case, and a two-seater for choice; this reduces prime cost and up-keep materially, for, if a car is overloaded, it ruins the tyres very quickly, and if you have only two seats, this prevents overloading. Also, in some districts, if the roads are not mended with limestone, these cars can be run without non-skids. The number of cylinders is a matter of choice; obviously, four are better than one, but four need a little more attention. For country work a magneto should be fitted, in conjunction with the ordinary battery and coil, but this refinement is expensive, as it is not a standard on these small cars. A glass screen and hood add much to the comfort of the passengers. It will be seen that it is necessary to spend about £250. Less capital expenditure than this cannot be advised if 5,000 miles per annum are to be covered, and the car expected to wade through mud and against wind. For fine-weather work a smaller expenditure is possible, but, in the end, the smaller car will cost more in repairs, and the saving will not be what it might be expected. In reply to the second portion of the letter:—I ran a small 6½-h.p. car for 2½ years, with an outlay averaging £45 per annum, but this was an immature car, and needed too many repairs. By that I mean some parts were not up to their work, and so wore out quickly; also they were not protected from mud. N.B.—That car is running still in the hands of a friend of mine.

For the last year I have run a 15-h.p. five-seated car, often overloaded, including a tour of 1,000 miles, and my expenses for 5,000 miles are as follows, not including shillings:—Tyres, £53; petrol, £20; repairs, £5; oil, etc., £5; insurance, £13; total, £96. Taking expenses at £100, and mileage 5,000 (this is taken with a milometer), the average cost is 4·8d. per mile.

My tyre bill is too heavy, owing to two circumstances—first, a 300-mile trip at Easter, over new-laid stones, often with five up; and, secondly, an unnoticed puncture, which ruined a tyre and tube. Weight of car, 24 cwt., including all extras.

From the above, it is evident that a car of 10-h.p., with two seats, could easily be run for £50:—Tyres, £20; petrol, £12; oil, £3; repairs, £5; insurance, £8; total, £48.

I will be happy, if "M.D." is going to buy a car, to give him any advice and assistance if he will write direct to me.

I am, Sir, yours truly,

Lex.

February 1st, 1908.

THE "STAR" AND THE MEDICAL PROFESSION.

To the Editor of The Medical Press and Circular.

Sir,—When I wrote that it seemed not necessary to continue this controversy in your pages I had in view your professional readers alone. These had, I was sure, read enough to make plain the deplorable, bitter prejudice towards the medical profession displayed by the editor of the *Star*, and to estimate his claim to speak with authority on the subjects under discussion. He shows himself unacquainted with coarse facts essential to the formation of a sound opinion, and he gives no evidence whatever that he possesses the rudimentary knowledge needed even for the understanding of the scientific problems involved. His prejudice is again displayed to-day, when a charge of inhumanity alleged against two practitioners is put forth as though, if true, it should disparage the whole profession. One wonders whether the editor fully realises his responsibility in these matters, whether he bears in mind the fact that his paper forms the sole literary pabulum for thousands of poor and ignorant readers, who accept his utterances as their gospel; whether he has considered what the cost in suffering and misery may be if he beguile his simple readers into neglect of the help in preventing, relieving, and curing disease which medical and surgical art now so surely offers in many directions; and whether he has considered the harm that is being done to the poor and ignorant in driving them into the hands of the cruel quacks whose advertisements crowd the pages of so many newspapers. To point out all the misconcepitons which the editor's letters suggest he labours under would occupy pages of your space. The fact that he writes to you again shows, at any rate, that his mind is not closed; and, if you will allow me, I will point to one or two directions in which, if he desire enlightenment, he may inquire and gain it. In the first place, he seems not to be aware that a considerable section of the profession, not only in these islands, but throughout the civilised world, are not called upon, during the whole of their careers in their special departments of practice, to perform the operation of vaccination. These include many thousands engaged only in scientific work, and it is impossible to find one in a thousand among all these experts of experts who does not have his own children vaccinated. Does the editor of the *Star* insist that these men err through ignorance? Does he suggest any sordid motive for their conduct? Does he believe that they would uphold vaccination by their personal testimony if not convinced that it was at once necessary and harmless? We all know the danger of blindly accepting authority in matters of opinion; but in matters of scientific experiment we accept as true the testimony of an army of separate independent investigators, who state that the experiment is always followed by the same result, for we know that we can verify the statement by making the experiment for ourselves. The vaccination experiment has been made by tens of thousands of qualified observers, and its efficiency for its purpose and its harmlessness have been demonstrated millions of times since Jenner's discovery. Then, does the editor really know anything at all about the scientific aspect of the case, especially as viewed in the light of the new bacteriological knowledge of the present day? Does he suggest any scientific facts going to show the possibility of the convection of disease through vaccine lymph taken from the calf? Does he suggest that diseases like syphilis or tuberculosis could be so conveyed? And does he suggest that, if this were possible, the evidence would not be overwhelming, and that cases would not present themselves to observation in numbers every day? The fact is that the anti-vaccination propaganda is based almost entirely upon falsehood and gross, vulgar superstition. The evidence is of the crudest and most barbaric *post hoc propter hoc* variety. The vulgar ignorant are told that the operation is harmful, and they are ready to ascribe to it every complaint or disease to which a child is liable. The baby was vaccinated, and later on developed, for example, tubercular gland disease or syphilis, clearly inherited from the parents, and the vaccination must have formed the cause! In the very few cases, during half a century, in which an inquest has been held on an infant, the death of which has been ascribed to vaccination, it has been very rarely possible, after the most careful investigation, to trace any connection whatever between the alleged cause and the result. Will not the editor of the *Star*, for the sake of his ignorant readers, agree to remain neutral in these questions until he has mastered the necessary knowledge he now clearly lacks?

I am, Sir, yours truly,

January 29th, 1908. A SURREY DOCTOR.

CHRISTIAN SCIENCE AGAIN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. Dixon denies that Christian Science is either unscientific or blasphemous. He calls your statement "a colossal generalisation," as though the "size" of a generalisation had anything to do with its truth. This phraseology is a good example of the tall talk that serves as Christian Science literature, and is worth passing notice on that score. As to the blasphemy, with which, by your leave, I would like to deal briefly first, I would point out that if to lower Divine Providence, the Omnipotent and Omniscient, to the level of an African fetish, constitutes blasphemy, then Christian Science is certainly blasphemous, and blasphemous in the eyes not only of Christendom, but of Judaism, Buddhism, Shintoism, and every elevated religion which worships a real God and not an artificial idol of its own manufacture. We cannot explain the mystery of human suffering, but we know that disease and pain exist, and have always existed for countless generations, not only in Christian lands, but among the myriads who have never heard, and cannot in our time hear, of the name of Christ. We are told by the Christian Scientists that pain and anguish can be done away with by belief in certain dogmas or creeds, and by performance of certain rites prescribed by their special ritual; and we are thus also told that the Omnipotent allows the vast mass of human misery due to disease to continue unchecked, and dispenses His mitigating favours only to those who know how to gain His ear and propitiate Him by their ceremonies and prayers. No other word than blasphemous can properly characterise such a cult. As to the science of it, the phenomena of disease are the outward show of solid concrete facts, the results of the action and reaction of matter and force. To profess, for example, to eliminate disease, due to the reception of solid, tangible doses of specific poisons into the system, by the induction of a certain form of religious emotion within the patient, and by the prayers of ministers of the cult, is to profess to work miracles. It is not unscientific; it is non-scientific; it is pernicious nonsense.

I am, Sir, yours truly,

January 30th, 1908. HENRY SEWILL.

TRYPSIN AND CANCER—THE QUESTION OF PRIORITY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—By universal consent, there are two crucial points that establish scientific priority These are—(1) priority of publication, and (2) priority of practice, and Dr. Saleeby, in his letter of January 29th, has conceded both these points to me with regard to the treatment of cancer by trypsin.

I fail, however, to comprehend how Dr. Saleeby can reconcile the statement in his letter to the effect that "there has never been any question as to Dr. Shaw-Mackenzie's claim" with the following expression of opinion which appears in his book, p. 68—viz., "Only a few weeks after Dr. Beard's lecture, Dr. Shaw-Mackenzie began the hypodermic use of trypsin in cancer, and to him undoubtedly must be awarded the credit of being the first physician to employ the new treatment," while, in addition, in the preface to his book he refers to "the new mode of attack indicated and initiated by Dr. Beard."

The obvious and only interpretation to be placed on these statements and on Dr. Saleeby's reservation of "priority of idea," is, that the trypsin treatment of cancer is due to Dr. Beard, whereas it was introduced by myself (*Lancet*, February 11th, 1905), based on a pancreatic theory published by me (*Lancet*, January 14th, 1905)—in continuation of my own work and question in this direction, previously published—and absolutely independently of any other investigator.

In view, therefore, of the contradictory statements to which I have referred above, I do not feel myself called upon to discuss the further points which Dr. Saleeby has raised in his letter.

I am, Sir, yours truly,

J. A. SHAW-MACKENZIE, M.D. (Lond.).

London, January 31st, 1908.

OBITUARY.

DR. ANTONY ROCHE.

WE regret to announce the death of Dr. Antony Roche, which occurred on Wednesday, the 29th ult., at his residence, 60, Lower Baggot Street. Dr. Roche for many years has been a well-known figure in medical circles, and has done much by his energy as a popular lecturer to improve the general hygiene of the city. He took the diploma of the King's and Queen's Colleges of Physicians in 1871, after a distinguished career as a student, and, on the death of Professor McSwiney, was appointed to the Chair of Medical Jurisprudence and Hygiene in the Cecilia Street School of Medicine. He has also been for many years Examiner in Public Health in the Royal University. Dr. Roche was a most determined advocate of improved housing of the working classes, and, by persistent agitation through letters in the press and popular lectures, did much to prevail on the municipal authorities to remedy the evil of overcrowding in the city. His efforts in this direction also tended to inaugurate the main drainage scheme. For many years Dr. Roche has bestowed much attention on the tuberculosis problem, and, long before the present anti-tuberculous crusade, his voice was raised in commending isolation and notification. In addition to his other appointments, he filled the position of Lecturer on Hygiene to St. Patrick's College, Maynooth. Dr. Roche's sterling qualities endeared him alike to his colleagues and his students, and his name will long be honoured, not only in Cecilia Street, but by the poor of Dublin. He has left a widow and five children to deplore his loss. At a specially convened meeting of the Medical Faculty of the Catholic University, the following resolution was passed unanimously:—"The Faculty of Medicine of the Catholic University desire to place on record their sense of the great loss which the School has sustained by the death of their esteemed colleague, Professor Antony Roche. An old student of the school, whose career was marked by the highest distinctions in all his classes, he has filled the Chair of Hygiene and Medical Jurisprudence in a manner to merit professional and public respect, and to earn the gratitude of the pupils, in whom he inspired a thorough devotion to scientific progress. The Faculty mourn the untimely demise of an honourable colleague, a professor of exceptional ability, a warm-hearted friend, and a strenuous advocate of the educational claims of the Irish people. They tender to his bereaved family a sincere expression of condolence in their affliction."

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons in Ireland.—Annual Dinner.

On Saturday the annual dinner of the Royal College of Surgeons took place in the dining hall of the College, Stephen's Green. The President, Sir H. R. Swanzy, occupied the chair. There was a large attendance. After dinner and the toast of "The King," the Vice-President, Dr. Lentaigne, proposed "The Guests." The Very Rev. the Dean of St. Patrick's, the Hon. the Recorder, and the President of the Royal College of Physicians responded.

Dr. J. Magee Finney, President of the Royal Academy of Medicine, proposed the toast of "The College of Surgeons." The toast was warmly received.

The President, in responding, said that their college had unquestionably had a distinguished record. Many of its members in the past had become most eminently distinguished. But what was more important in this work-a-day world was that the vast army of the rank and file had gone forth well-equipped for the battle of life, and had carried with them over the face of the earth the healing art and the good name of that college of which they were proud. In a few days the Royal College of Surgeons would have reached the end of its one hundred and twenty-fourth year. One hundred and twenty-four years was not, after all, a great age for a college—as the lives of colleges and universities were reckoned. Yet in that country, where they saw colleges and universities springing up, as he might say, in the night—or even in the course of a Parliamentary debate—and spending so short a life that one had really hardly time to get a nodding acquaintance with them—one hundred and twenty-four years was really quite a respectable span of life. Within the last eight or ten years there had been very important achievements and improvements in that college, and in the school they had provided many improved facilities for the teaching of bacteriology and of physiology, and they had also done a great deal to promote the comfort of the students.

Professor William Carter, of Liverpool.

There was a large and enthusiastic gathering at the Adelphi Hotel, Liverpool, on the 25th ult., on the occasion of a public dinner that had been accorded Dr. Carter on his leaving that city. The occasion was also taken advantage of for the presentation of a portrait in oils, painted by Mr. F. T. Copnall. The chair at the dinner was taken by the Lord Mayor, Dr. Caton. In proposing the toast of the evening, "Our Guest," his lordship referred in felicitous and sympathetic terms to his 40 years' friendship with the guest of the evening, and expressed his deep personal regret that he was leaving Liverpool. He well remembered when Dr. Carter first came to Liverpool (and so also does the present writer) being impressed with the fact that he was not only a medical man, but a graduate in law. He remembered, too, how his professional brethren soon learned to esteem Dr. Carter and to recognise his great learning, and his great ability as a physician. Dr. Carter had worked hard for the Medical School for 40 years. He also referred to his long association with the Royal Southern Hospital as physician; to his work as city magistrate; his labours on behalf of temperance, and his close association with the School of Tropical Medicine in Liverpool. Not many knew how generous he had been, but some of them knew how open his purse had been to every call of poverty, sickness and want.

The Bishop, who spoke to the toast, thought that the words of Hamlet as applied to his father were also applicable to Dr. Carter—"He was a man, take him for all in all, we shall not look upon his like again."

Dr. Wm. Alexander also supported the toast, and his words bore the greater weight as he had for 20 years been Dr. Carter's colleague at the Royal Southern, and had, as a matter of fact, been his surgeon, and Dr. Carter had been his physician. As showing his colleague's open mind, he mentioned that, although Dr. Carter held such strong opinions in regard to alcoholic drinks, he recognised the value of alcohol in the treatment of diseases, and used it where necessary.

Dr. Carter, in returning thanks, mentioned some particulars of his career. Until a fortnight ago he said he had been supposed to be an Irishman. He had taken the Fellowship of the Royal College of Surgeons in Ireland, and had married an Irish wife. Dr. Carter, as most of his friends are aware, was born at Newbury, Berks, being the son of a medical practitioner there, so that for him the science of medicine has claims by way of heredity. Of his career it would be superfluous to speak. We wish him a happy and green old age in his retirement, and we feel sure that, with his books, his garden, and his botany, of which he has always been an enthusiastic lover, he will find plenty to occupy his time and his thoughts.

Libel Actions by Dr. Hebert settled out of Court.

We have been asked to insert the following statement as to Dr. Hebert's libel actions:—In consequence of certain reports which appeared in the Press in relation to the Versailles affair, Dr. Hebert issued writs against the following newspapers, viz.:—The *Daily News*, the *Daily Mirror*, the *Daily Mail*, the *Evening News*, the *Pall Mall Gazette*, the *Evening Standard*, the *Daily Express*, the *Westminster Gazette*, the *Manchester Courier*, the *Glasgow Evening Times*, and the *Liverpool Echo*, for publishing libellous articles sent out by the Exchange Telegraph Company, Limited, referring to Dr. Hebert in connection with a charge at Versailles against the woman Pesnel, *alias* Cesbron, and the case was settled out of Court by the payment to Dr. Hebert of the sum of £1,000 for damages and costs, and the undertaking, on the part of the said newspapers, to publish an apology of a form agreed upon, and which has already appeared in the *Daily Mirror* of January 10th last.

University of Durham.—Faculty of Medicine.—Alteration of Dates of Professional Examinations.

The attention of candidates is directed to the fact that the examinations in Medicine, Surgery and Hygiene will, in future, be held in March and July, instead of April and September, as hitherto. For particulars as to dates of forthcoming examinations see advertisement.

Conjoint Examinations in Ireland by the Royal College of Physicians and the Royal College of Surgeons.

The following candidates have passed the Third Professional Examination, January, 1908:—P. N. Allman, H. Gray, E. A. Gregg, J. T. Heffernan, L. Hynes, T. J. Lyons, J. Marmion, T. McDonald, H. G. Miles, A. E. Moore, W. P. H. Parker, J. Patton, P. M. Power.

Special Examination for the Diploma in Public Health.—E. E. B. Landon, M.R.C.S., L.R.C.P.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for The Medical Press and Circular.

RECENT SURGICAL LITERATURE.

The Contents of Irreducible Inguinal Herniæ in Female Subjects, and True Hermaphroditism.—Corner (*Brit. Med. Journ.*, Jan. 4th, 1908) states that the contents of irreducible inguinal herniæ in females differ in the most marked manner when found in adults and when found in children. In children some of the female internal genitalia are practically always found in the hernial sac. The author has tabulated 20 cases of these herniæ in female infants up to 13 months old. Ninety-five per cent. of these contained ovaries or tubes, or both. In 15 per cent. bowel was present as well. When irreducible, the hernia of a female child will be felt to contain a small rounded body about the size of a small pea, which is freely movable upon its pedicle. It is the ovary. When strangulated, there is a non-translucent mass over the external abdominal ring through which it protrudes. There need be no sickness, and the bowels will act. The lump gets larger and larger, but may cause the infant very little inconvenience. The diagnosis is easy. When the hernia is simply irreducible the ovary and tube can be readily felt. When the hernia is strangulated and has no impulse on crying, the diagnosis is not difficult to make on account of the non-translucence of the swelling, and the association of it with no more symptoms than perhaps some slight irregularity of the bowels and the digestion. The hernia is of truly congenital origin, but may not appear till shortly after birth. The irreducibility to some extent depends on the difficulty that there may be in manipulating a small movable body through a small hole. Very occasionally these organs undergo spontaneous reduction. Operation is the only treatment, the gland being returned to the abdomen, and the sac removed. The use of the truss is contraindicated on account of the injury it may do to the gland. If left *in situ* the ovary is very liable to torsion of its pedicle, causing inflammation and destruction of the gland, or to the prevention of full maturition and development at puberty. In some cases, if the glands are removed and examined microscopically, they will be found to be immature testicles, not ovaries. When this is so the case is truly hermaphrodite—male generative glands and female generative organs. In 49 cases of irreducible inguinal herniæ in females between the ages of 15 and 91 years, four only contained internal generative organs, while 65 per cent. contained bowel. S.

The Treatment of Tuberculous Arthritis.—Primrose (*Canadian Journal of Med. and Surg.*, January, 1908) in general advocates conservative non-operative treatment in tuberculous arthritis, but recognises that operative measures are not infrequently indicated where the conditions are becoming rapidly worse, in spite of efficient conservative treatment. In tuberculous abscesses the great point is to avoid mixed infection by avoiding the drainage tube. Abscesses occasionally disappear spontaneously. When the abscess is enlarging progressively it should be incised by cutting into the cavity at a point which is not dependent, the incision being so placed that a considerable thickness of tissue is cut through before the cavity is reached, and not where the abscess approaches the skin. After evacuation of the contents the wall is thoroughly curetted, then rubbed with iodoform gauze and curetted again, the process being repeated till a smooth firm wall remains. The cavity is then flushed out with sterile water and carefully stitched up again without drainage. Occasionally the cavity fills up, and leakage occurs, the line of incision breaking down. The same process should be repeated a second time. Even a third operation may be necessary; but if a culture from the cavity shows pyogenic organisms, it is useless to persist. Excision of joints or less extensive operations are sometimes called for, as where serious destruction of a joint is threatened, or where constitutional symptoms become grave. Also in long-standing cases where septic sinuses exist amputation may be necessary. In cases of definitely localised areas of disease it is often possible to remove these foci without opening the articular cavity. The author removed diseased bone from the femoral neck by tunnelling through the great trochanter. S.

Appendicitis due to the Presence of Oxyuris Vermicularis.—Thrush (*Medical Record*, December 28th, 1907) describes a case presenting the usual classical symptoms of acute appendicitis. As medical treatment failed the appendix was removed by Dr. Wharton. It presented the characteristic appearances of acute infection, the only peculiar feature being a bulb-like expansion of the tip into a mass about one inch long and about double the calibre of the remainder of the organ. On dividing the appendix a thick mucoid substance was found, with a constriction above it, separating it from the rest of the appendicular canal. The mass contained a large number of worms moving around freely. There were about one hundred of these in various stages of development. Microscopically the diagnosis of oxyuris vermicularis was confirmed. Rectal examination showed an abundance of these worms. Evidently they had spread up from the rectum, and some of the ova becoming imprisoned in the appendix had developed and caused the attack of appendicitis. S.

Inoperable Sarcoma of the Neck Treated Successfully with Coley's Toxins.—Oliver (*Lancet-Clinic*, January 11th, 1908) reports the following case. The patient, æt. 52, had a tumour in the neck for 11 years, when it commenced to grow rapidly, and was removed. It proved microscopically to be a myxo-fibro-chondrosarcoma. New tumours appeared, and grew more rapidly than the original ones. They were situated at the angles of the jaw and along each carotid sheath. The right tonsil and side of the pharynx were pressed inwards by these masses, seriously encroaching on the lumen of the throat, and causing difficulty in swallowing. The right tonsil was indurated, ulcerated, and had the appearance of a malignant growth. An attempt was made to remove one of the tumours for diagnostic purposes, but it was so friable, vascular, and intimately united to the lower jaw that it was found impossible to remove the entire mass. A microscopic section of part of the removed mass showed chronic adenitis, but the subsequent history proved the malignant nature of the case. Coley's serum was injected from October, 1905, to March, 1906, about every other day. This was followed by marked local reddening of the skin over the masses, and also by a general reaction. During part of this period X-rays were also employed. In March there was scarcely a remnant of the original growth. Two months after leaving hospital the patient developed, apparently spontaneously, a severe attack of facial erysipelas, which quickly recovered under treatment. The tumours disappeared entirely, and remained away until November, 1907, when there was a recurrence in the right parotid region. He is again under treatment. The author used this treatment in three cases of tuberculous cervical adenitis. The reaction was not well marked, and no good results were obtained in this class of case. The author considers that about 10 per cent. of sarcoma cases are saved by Coley's treatment. S.

Modifications of the Movements of the Knee-Joint Directly Consequent on Injury.—Sir Wm. Bennett (*Brit. Med. Journ.*, Jan. 4th, 1908) divides these cases into two types—(*a*) those in which the joint is completely locked; and (*b*) those in which flexion to a limited degree is possible. The commonest causes of complete locking in patients under 35 are displaced semilunar cartilages. After that age it is usually due to hypertrophied synovial fungus, especially in osteo-arthritis. Some cases in young patients are due to an abnormal flap of synovial membrane which is sometimes found dependent from the patella. These occasionally become caught between the bones of the joint. Rarely, locking is due to a piece of bone broken off one of the condyles. The author does not consider that a displaced tendon of popliteus muscle is a possible cause. Locking in the absence of an anæsthetic may be caused by muscular spasm, secondary to pain. Restriction of movement in the joint may be due to small foreign bodies acting as a wedge in certain positions of the joint only. A fairly common cause is ruptured conical ligaments following a violent forcing backwards at the knee-joint. The commonest causes of restriction of movement are extra-articular, as rupture of the inner head of the gastrocnemius, thrombosis from injury to a vein, and formation or rapid increase of a popliteal bursa in osteo-arthritic subjects. If extension is free, the question of foreign bodies between the bones may be for practical purposes set aside. S.

Acute Suppuration in Thyroid Adenoma.—T. Legg (*Lancet*, January 25, 1908) reports the case of an Italian, æt. 26. He was suffering from typhoid fever, which ran an ordinary course, but at the end of five weeks his temperature, instead of dropping, began to rise again, and a tender swelling was discovered in the right lobe of the thyroid. The gland had been enlarged for at least two years, presenting the appearance during this time of an ordinary goitre. In four days' time the swelling had become much larger, the whole of the right lobe being globular and elastic. The evening temperature was over 102°. An incision was made into this swelling, and about two ounces of pus were evacuated. The cavity was drained, and healed in the course of a couple of weeks. From the pus evacuated cultures of typhoid bacillus were obtained without any difficulty. The formation of an acute abscess in an enlarged thyroid gland is always a rare occurrence, but probably happens more often after typhoid fever than under any other conditions. Once a diagnosis of pus is made, the abscess should be opened at once, as otherwise it is liable to penetrate the capsule of the gland and lead to a diffuse cellulitis of the neck and mediastinum, or may open into the trachea or pharynx. Whichever of these occurs the result will in all probability be fatal. G.

Anastomosis of the Ureter.—Leguen (*Le Progrès Médical*, August, 1907) thinks that the causes of failure in many cases of ureteral anastomosis are due primarily to a fault of union by primary intention. When this occurs, either immediate or remote failure is bound to ensue. It is well to remember that because a case clinically appears well, we cannot regard the ureteral anastomosis as successful until the ureter has been catheterised. The author mentions a case of ureteral implantation in the bladder. This operation was performed for a patient who was continually getting severe attacks of renal pain of an obstructive nature. This obstruction was proved to be due to the retraction and thickening of a ureter which had been previously injured. The operation was apparently quite successful, the renal crises all ceased, but three years later the patient died, and the post-mortem examination showed the anastomotic opening completely obliterated, and the kidney had become entirely obliterated. G.

Congenital Hydronephrosis.—H. Coffin (*Post Graduate*, January, 1908).—The congenital forms of hydronephrosis are rarely bilateral. The condition may result from abnormal position of the kidney, atresia of the ureter, abnormal valvular formations, phymosis, and abnormal entrance of the ureters into the bladder. The retained urine distends the ureter, extends to the pelvis of the kidney, then to the tubules, causing degeneration finally of the parenchyma of the kidney. The author reports two cases—a child, aged 23 days, died, after some convulsive attacks, and the passage of a small amount of blood-stained urine. P.M.—Acute parenchymatous nephritis, the ureters were distended to twice their natural size, both pelves were dilated, the right ureter was markedly constricted 4 c.cm. below the kidney, at its entrance into the bladder there was another constriction causing dilatation above. The left ureter was narrowed at its entrance into the bladder, and above this the tube was greatly dilated. The bladder was normal, and contained a little bloody urine. The second case was that of a child who only lived six weeks, and died of an acute pleurisy, P.M. —There was acute nephritis and hydronephrosis of the right kidney. The pelvis of the kidney was much dilated, five cm. below there was a tight constriction of the ureter. There was a second stricture of the right ureter at its entrance into the bladder. The bladder was normal. In neither case was there any stone in any part of the urinary organs which could possibly have caused the trouble. G.

Cocaine in Vomiting after Anæsthesia.—H. Freund (*Wien. Klin. Woch.*, November, 1907) believes that if the gastro-intestinal canal is completely anæsthetic, all reflex irritability must necessarily be abolished. Vomiting usually occurs after a general anæsthetic as soon as the patient regains consciousness, though its appearance may be delayed for some hours. No one method of combating this vomiting can succeed, as there are two varieties of it—central, due to irritation of the vomiting centre in the medulla oblongata, and peripheral vomiting, due to reflexes originating in gastric and intestinal irritations. The former occurs during the induction of anæsthesia as the stage of excitement is passing into that of narcosis, the latter depends partly on the irritation caused by saliva impregnated by the anæsthetic, and partly by the secretion of the anæsthetic by the gastric mucosa. The author treats post-anæsthetic vomiting in the following way: Half an hour before the administration of the anæsthetic 1-6th of a grain of morphia and 1-200th of a grain of scopolamine is given hypodermically, just before the operation is completed 1-3rd of a grain of cocaine is given hypodermically to the patient. Out of 110 cases so treated only 14 had any vomiting after the anæsthetic. G.

Six Cases of Congenital Word-blindness affecting Three Generations.—In the *Ophthalmoscope* of September 1, 1907, Sydney Stephenson relates the above experience. The symptoms of the case which came under observation, and which gave rise to an inquiry into her family history, were of the usual kind, and similar to those recorded by other observers. The young lady, aged 14, was well developed and strong, with good hearing and full visual acuity, with weak correcting glasses. Her education was commenced before she was seven years old, and after two years she could read her letters at sight. When ten she could read aloud with difficulty such short words as "dog," "cat." During the following two years considerable improvement took place in her reading. Although distinctly intelligent, the patient was two years older than the others in her class. There was, as usual in these cases, no difficulty with figures, arithmetic being her strong point. Good at geometry, and passed with honours three examinations in drawing. Although learning music for six years there was difficulty in reading the notes. The family history revealed that the maternal grandmother learned to read with difficulty, and was seldom seen to read to herself. The patient's mother (unaffected) was the eldest of eight children, four of whom showed symptoms of congenital word-blindness. Of these, Barbara, now aged 35, could read slowly when 14, seldom reads for pleasure, and is very musical. Charles, who died at 32 years, was educated and clever, but had more difficulty in reading than Barbara. A girl who died at 8 years had a difficulty in learning to read, and Bella was worse than Charles. A brother, aged 16, had no difficulty in learning to read. It will be noted that the condition was passed from the second to the third generation by a female, who herself was unaffected. M.

NOTICES TO CORRESPONDENTS, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. Half Page, 13 insertions, at 35s.; 26 at 32s.; 52 at 30s. Quarter Page, 13, at 18s.; 26 at 16s.; 52 at 15s. Eighth Page, 13, at 9s.; 26 at 8s.; 52 at 7s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

VETERAN NURSE.

At the age of 104 Mrs. Mary Nelson, formerly an Army nurse, who was with Miss Florence Nightingale's nursing staff in the Crimean war, and was an eye-witness of the charge of the Light Brigade, has died at Carrick-on-Shannon (Co. Leitrim).

Pes Anserinus.—We have looked into the matter to which our correspondent refers, and our information goes to show that his assumption is quite correct.

Dr. G. J. P.—We are sorry to have to hold your letter over owing to the crush this week.

THE LATE ATTORNEY-GENERAL.

The lamented death of Sir John Lawson Walton reminds us that he was counsel for the plaintiff in a case which attracted great attention in medical circles some years ago. It was the action brought against the late Dr. William Playfair by a patient for breach of professional confidence, viz., communicating information to his wife. The verdict went against him, and he had to pay £12,500 damages.

Laboratory Notes.—Under the above heading last week we inserted a notice of Messrs. Allen and Hanbury's preparation "Sauerin"—by a typographical error this was spelt "Sanerin." At the same time we should like to mention that although Professor Metchikoff's name is mentioned, he is in no way responsible for the preparation.

N. 3 Med. Journ.—We are glad to see you read this column, and should be still happier if you thought more of us when quoting.

"OPHTHALMIA" NEONATORUM.

Up-to-date Medical Student *(loquitur)*: "Please, sir, what is ophthalmia neonatorum?"

Elderly Ophthalmic Surgeon: "Inflammation of the conjunctiva of the infant."

U.-t.-d. M. S.: "Yes, sir, I know—but what is 'ophthalmia'?"

E. O. S.: "Well, it doesn't mean inflammation of the eye——"

U.-t.-d. M. S.: "Thank you. But what I want to know is—wouldn't it be more correct to say *conjunctivitis* neonatorum instead of *ophthalmia* neonatorum?"

E. O. S.: "Certainly not. Hippocrates used the word 'ophthalmia,' and later authors after him have done the same."

U.-t.-d. M. S.: "I'm so much obliged. I'll make a note of that."

C. A. M. B. (National Canine League).—Can you seriously expect us to publish a letter containing such an expression as yours begins with? We certainly refuse to give currency to such a story as you introduce, unless we are satisfied that it is literally true; that it took place in England within recent years; that no anæsthetic was administered; and that the case had been brought to the notice of the Inspector under the Experiments of Animals Act, and not dealt with by him. If we are satisfied as to these points, we should do more than merely publish it without comment. If it does not fall in with these conditions, it is no more in point than the horrors of the Inquisition.

Meetings of the Societies, Lectures, &c.

Wednesday, February 5th.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. J. Berry: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. R. H. J. Swan: Malignant Cutaneous Tumours.

Thursday, February 6th.

The Throat Hospital (Golden Square, W.).—5.30 p.m.: Mr. Faulder: Lecture:—Surgical Anatomy of the Tympanum and Mastoid Process.

North-East London Clinical Society (Prince of Wales's General Hospital, Tottenham, N.).—4.15 p.m.: Clinical Cases.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. R. Jones (Liverpool): The Present Position of Arthrodesis and Tendon Transplantation.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Throat Operations (Mr. Carson).

Great Northern Central Hospital (Holloway Road, N.).—2.30 p.m.: Medical In-patients (Dr. Morison).

St. John's Hospital for Diseases of the Skin (Leicester Square, W.C.).—6 p.m.: Lecture:—Dr. M. Dockrell: Syphilis: Papular (I., Miliary; II., Lenticular; III., Squamous; IV., Moist), Pustular and Tuberculous.

Friday, February 7th.

Royal Society of Medicine (Laryngological Section) (20, Hanover Square, W.).—5 p.m.: Dr. W. Williams, Sir Felix Semon, Dr. J. Donelan, Dr. St.Clair Thomson and Dr. J. Horne: Cases and Specimens.

West Kent Medico-Chirurgical Society (Miller Hospital, Greenwich, S.E.).—8.45 p.m.: Dr. F. E. Taylor: Uterine Hæmorrhage.

West London Medico-Chirurgical Society (West London Hospital, Hammersmith Road, W.).—8 p.m.: Pathological Meeting. Specimens will be shown.

Society of Anæsthetists (20, Hanover Square, W.).—8.30 p.m.: Adjourned Discussion on Status Lymphaticus.

Royal Society of Arts (John Street, Adelphi, W.C.).—8 p.m.: Mr. W. Burton: The Hygiene of the Pottery Trade. (Shaw Lecture on Industrial Hygiene.)

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Dr. D. Grant: Clinique. (Ear.)

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques: Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. M. Leslie).

Great Northern Central Hospital (Holloway Road, N.).—3.30 p.m.: Lecture:—Dr. C. E. Beevor: Diagnosis and Treatment of Hemiplegia.

Monday, February 10th.

Royal College of Surgeons of England (Lincoln's Inn Fields).—5 p.m.: Erasmus Wilson Lectures:—Mr. S. G. Shattock, F.R.C.S.: Ovarian Teratomata.

Appointments.

Cooper, A. J. Sisson, L.R.C.P. and S.Irel., Medical Officer and Public Vaccinator for the Fontmell District.

Friend, Gerald Edward, M.R.C.S., L.R.C.P.Lond., Superintendent and Resident Medical Officer at St. George's Hospital.

Glenny, Edward T., M.B., B.S.Lond., L.R.C.P.Lond., M.R.C.S., Medical Officer to the Bristol Dispensary.

McCandless, R., M.B., B.Ch.R.U.I., Certifying Surgeon under the Factory and Workshop Act for the Rathfriland District of the county of Down.

Morris, Leonard Newsom, L.R.C.P.Lond., M.R.C.S., Medical Officer to the Bristol Dispensary.

Phillips, Hugh R., M.D.Edin., Physician to Margaret Street Hospital for Diseases of the Chest.

Telling, W. H. Maxwell, M.D., B.S.Lond., M.R.C.P., Honorary Physician to the Cookridge Convalescent Hospital, near Leeds.

Vacancies.

Castlebar Union.—Medical Officer. Salary, £110 per annum. Applications to J. M. Quinn, Clerk of Union. (See Advt.)

Birkenhead Borough Hospital.—Senior Resident House Surgeon. Salary, £100 per annum and fees. Applications to the Hon. Secretary.

Parish of Lambeth.—Board of Guardians.—Third Resident Assistant Medical Officer. Salary, £125 per annum, with the usual residential allowances. Applications to the Medical Superintendent at the Infirmary, Brook Street, Kennington Road, S.E.

County Borough of Great Yarmouth.—Assistant Medical Officer of Health. Salary, £200 per annum. Applications to W. Edgar Stephens, Town Clerk, Town Hall, Great Yarmouth.

Drogheda Union.—Medical Officer. Salary, £110 a year. Applications to Thomas Dowdall, Clerk of Union. (See Advt.)

Births.

Buchanan.—On Jan. 30th, at Kirkgate, Thirsk, the wife of Walter J. Buchanan, M.B., of a son.

Edwards.—On Feb. 2nd, at Granville House, Bridport, the wife of Charles Edwards, M.R.C.S., of a son (stillborn).

Marriages.

Reynolds—Romer.—On Feb. 1st, at Holy Trinity Church, Tulse hill, London, Russell John Reynolds, M.B., B.S. (Lond.), L.R.C.P., M.R.C.S., only son of John Reynolds, M.D., F.R.G.S., of 11, Brixton-hill, London, to Anna Thekla Henrietta Römer (Annie), only daughter of Adolph Römer, of "Brynbella," Tulse-hill, London.

Deaths.

Green.—On Feb. 1st, at Greyroofs, Wimbledon Hill, London, Mowbray Vincent, only son of Dr. and Mrs. Vincent Green, in his 6th year.

Holland.—On Jan. 31st, Charlotte Elizabeth Holland, dearly beloved wife of Dr. Edmund Holland.

Marley.—On Jan. 26th, at Mellingey, St. Issey, Cornwall (late of Padstow), Henry Frederick Marley, L.R.C.P.Lond., M.R.C.S.E., last surviving son of the late M. P. W. J. Marley, F.R.C.S., of Burlington Gardens, London, W., aged 76.

Pettigrew.—On Jan. 30th, at The Swallowgate, St. Andrews, James Bell Pettigrew, M.D., LL.D., F.R.S., F.R.C.P., Chandos Professor of Medicine and Anatomy in the University of St. Andrews.

Respiratory Inflammations.

There are many reasons why Angier's Emulsion is so extensively employed in bronchitis and the various inflammatory affections of the respiratory organs incidental to the winter months. The first and most potent of these reasons is the universally attested clinical fact that the remedy quickly relieves these conditions. Equally true is it that the Emulsion exerts its curative influence in both the acute and chronic forms of bronchitis. Cough is checked, bronchial irritation allayed, and expectoration facilitated. No other remedy has such sedative demulcent and lubricating effects, while its stimulating influence on nutrition overcomes the oft-present element of systemic depression. It is no exaggeration to state that Angier's Emulsion is not only the simplest but likewise the best treatment for acute and chronic inflammatory affections of the respiratory organs.

FREE SAMPLES TO THE MEDICAL PROFESSION.

ANGIER'S EMULSION

(Petroleum with Hypophosphites).

THE ANGIER CHEMICAL CO., Ltd., 32 Snow Hill, LONDON, E.C.

By Appointment to H.M. the King.

Cyllin Inhalant

as given off by the Cyllin Inhalator is most beneficial in all diseases of bacterial origin in the mucous lining of the throat, nose, and ears.

In Influenza

its germicidal action on the specific bacillus situated in the superficial layers of the mucous membrane of the respiratory tract, renders valuable assistance.

Cyllin is also put up as a Syrup, and in Capsule form (Palatinoids) for stomachic and intestinal antisepsis.

See pamphlet entitled "Standard Chemical Disinfectants." Copies, together with working samples, sent gratis and post free on applying to

Jeyes' Sanitary Compounds Company, Ltd.,
64, Cannon Street, London, E.C.

SCHERING'S MODERN THERAPEUTICS

EXODIN

Tasteless and Odourless Laxative, in Table form
Mild, but Sure and Safe.

SUBLAMIN

Non-irritant Sulphate of Mercuric Ethylendiamine
Preparation for Hand Disinfection.

EMPYROFORM

Dry, almost Odourless Tar Preparation. No Local Irritation or Intoxication. Excellent in treatment of Eczema, Psoriasis, etc.

EUPHTHALMIN

Powerful Mydriatic. Excellent in Acute and Chronic Iritis. Far superior to all other Agents for Ophthalmoscopic Examinations.

BETA EUCAIN LACTATE

Local Anæsthetic par excellence. Soluble up to 20%. Toxic effects reduced to a minimum.

PIPERAZINE **PHENOCOLL** **CHLORALAMID** &c.

FOR SAMPLES AND LITERATURE APPLY TO

A. & M. Zimmermann, 3 LLOYD'S AVENUE,
London, E.C.

S.H

Xeroform An absolutely non-poisonous desiccating, and deodorising **Dusting Powder** for wounds. Actively promotes the growth of epithelium, and does not irritate either the wound or the surrounding skin. Excellent for dry dressings and also for dressings which are seldom changed. Has a specific action on **Moist Eczema, Ulcers of the Leg,** and **Burns.**

Collargol An admirable remedy in **Septic Processes, Puerperal Diseases,** etc. Administered intravenously it produces no ill-effects of any kind. It may also be given by the rectum, or by the mouth, or by inunction in the form of **Credé's Ointment.** Useful in the treatment of **Wounds** and **Infectious Diseases of the Eye** and for **Washing out the Bladder.**

Salit A Salicyl Compound in the liquid form. Moderate in price and gives immediate relief when rubbed on the seat of pain in **Rheumatism.** Does not injure the skin even when undiluted. Has no ill effect on the internal organs.

Novargan A Soluble Albumen-silver Preparation for the treatment of **Gonorrhœa,** especially in the **acute** stage. Even in the concentrated form it does not irritate the mucous membrane.

Samples and Literature may be obtained of . .

Annotations

CALCIUM LACTATE

Recent research has shown that urticaria or nettle rash, erythema pernio (chilblains), certain forms of albuminuria and of headache, serum rashes and other affections, are intimately related to, and may probably depend upon, deficient coagulation power of the blood. Salts of calcium increase blood coagulability, and their administration has proved very successful in the conditions referred to.

'TABLOID' Calcium Lactate is specially suitable for the purpose. It presents the pure active salt in exact amount, convenient for treatment. It is non-irritating, readily soluble and easily absorbed without causing digestive disturbance. It produces its effect quickly and certainly.

Aneurism and various forms of hæmorrhage are also benefited by the use of 'Tabloid' Calcium Lactate. The salt is prescribed in hæmorrhagic small-pox, and as a preventive and curative in hæmophilia, in uterine hæmorrhages and preliminary to surgical procedure, where its use may obviate dangerous bleeding.

'Tabloid' Calcium Lactate, gr. 5, is supplied to the Medical Profession, in bottles of 25 and 100

Trade 'XAXA' Mark
(ACETYL-SALICYLIC ACID)

Salicylic acid and its simple salts have serious drawbacks; they create gastric disturbance and may produce depressant and toxic effects. Acetyl-salicylic acid possesses the therapeutic value justly attributed to salicylic acid and the salicylates without attendant disadvantages.

'TABLOID' 'Xaxa' contains no free salicylic acid, but presents perfectly pure acetyl-salicylic acid in a manner conducive to easy, regular administration and most satisfactory therapeutic results.

Being insoluble in the stomach, 'Xaxa' produces neither gastric discomfort nor digestive derangement. It passes unchanged into the intestine, where it is decomposed by the alkaline secretions, and salicylic acid is liberated. The gradual absorption and elimination of the salicylic acid prevent cumulative toxic effects.

'Tabloid' 'Xaxa,' gr. 5, is supplied to the Medical Profession, in bottles of 25 and 100, at 8d. and 1/6 each

'XAXA' AND PHENACETIN

'Xaxa' is frequently prescribed in combination with an analgesic and antipyretic, for which purpose 'TABLOID' 'Xaxa' and Phenacetin containing 2½ gr. of each is admirably adapted.

'Tabloid' 'Xaxa' and Phenacetin is supplied to the Medical Profession, in bottles of 25 and 100, at 8d. and 1/8 each

'XAXA' AND DOVER POWDER

The diaphoretic and anodyne effects of compound ipecacuanha powder are, at this season, of the greatest service, especially when combined with 'Xaxa,' which is conveniently done in 'TABLOID' 'Xaxa' and Dover Powder containing 2½ gr. of each.

'Tabloid' 'Xaxa' and Dover Powder is supplied to the Medical Profession, in bottles of 25 and 100, at 8d. and 1/8 each

Trade 'XAXAQUIN' Mark
(QUININE ACETYL-SALICYLATE)

This new quinine salt, manufactured at the 'Wellcome' Chemical Works, combines the therapeutic activities of quinine and salicylic acid and possesses advantages over the ordinary salicylate of quinine similar to those which 'Xaxa' possesses over salicylic acid.

'Tabloid' 'Xaxaquin,' gr. 3, is supplied to the Medical Profession, in bottles of 25 and 100

'XAXA' AND 'XAXAQUIN'

This combination presents the valuable antiseptic, antipyretic and specific properties of the salicylates, without their disadvantages, and combines with them the antiperiodic and antipyretic effect of quinine. The value of such a combination in the early months of the year is obvious. Each product contains 'Xaxaquin', gr. 2, and 'Xaxa', gr. 3.

'Tabloid' 'Xaxa' and 'Xaxaquin' is supplied to the Medical Profession, in bottles of 25 and 100

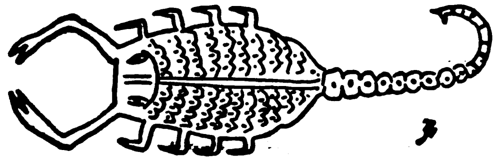
QUININE AND CAMPHOR

Antipyretic, antiseptic, diaphoretic and expectorant. This combination increases bodily resistance and fortifies the vital powers; it is of special service at this season of the year. 'TABLOID' Quinine and Camphor contains accurate weights of exceptionally pure ingredients. It enables quinine to be taken readily and easily, and allows of regular and effective administration. It presents obvious advantages over nauseous mixtures.

Each 'Tabloid' product contains quinine bisulphate, gr. 1, and camphor, gr. 1/5.

'Tabloid' Quinine and Camphor is supplied to the Medical Profession, in bottles of 25 and 100, at 6d. and 1/4 each

BURROUGHS WELLCOME & CO.
LONDON (ENG.) NEW YORK MONTREAL
SYDNEY CAPE TOWN



THE ZODIACAL SIGN OF THE SCORPION, AS REPRESENTED IN AN ANGLO-SAXON MS. OF THE X CENTURY

Diseases that were supposed to have their origin in the "flegm" were signified, according to an antient writer, by the following planetary positions:—

> "If the lord of the ascendant and the lord of the sixth house and the moon shall be in watery signs, they declare that the cause of the disease proceeds from the moist causes."

(COPYRIGHT)

CONSTELLATION SERIES—No. 125

The published statements of prominent surgeons of all countries show that

ARGYROL

(Silver Vitellin)

is the best silver salt, and that no known agent can compare with it in eradicating gonococcal and other infections, speedily and without discomfort to the patient.

Argyrol is used in 10 per cent. solution as injection in gonorrhœa every 3 hours; in 25 per cent. solution as instillation (diseases of eye) every half hour or hour, and in 25 per cent. solution as local application (throat, vagina, etc.) once daily.

Produced by

BARNES & HILLE,

32 Snow Hill, LONDON, E.C.

One unique effect of

OVOFERRIN

(Iron Vitellin)

is its property of improving the patient's general nutrition in a very striking manner.

Literature on Ovoferrin by recognized authorities in medicine in America and Europe, show that it is a hæmatinic and general tonic of very unusual value.

Ovoferrin is furnished by chemists, on prescription, in twelve-ounce bottles. The dosage is one tablespoonful in wine-glass of water or milk three times daily.

Produced by

BARNES & HILLE,

32 Snow Hill, LONDON, E.C.

VOL. CXXXVI. WEDNESDAY, FEB. 12, 1908. No. 7.

NOTES AND COMMENTS.

More Light. A nation which deliberately neglects the resources placed by Nature at its disposal must not seek sympathy if it suffers in health or pocket by its policy. The gospel of fresh air, imported from Nordrach, has—the gospel, that is, not the fresh air—captured thousands, and the gospel of light, imported from Denmark, has conquered its tens of thousands. Stuffiness and darkness are beginning to be recognised as unnatural conditions of life for *homo sapiens*, and there is no doubt these are very healthful notions. Electricity or incandescent gas have not the reputation of sunlight, either as agents for good or as bactericides, and yet civilised man deliberately prefers literally to turn night into day rather than endure the minor discomforts of getting up a little earlier in the morning and going to bed a little earlier at night. A gentleman named Mr. William Willett recently devised a plan for cheating us of our laziness without our knowing it; something like the "drink cures" which are put into the drunkard's cup to deprive him of his relish for strong liquor. Mr. Willett's proposal was that all public clocks during the Sundays of the month of April should be put forward twenty minutes, so that during the summer we should have an hour and twenty minutes more daylight during waking hours. Similarly during the month of September the Sunday time should undergo a complemental retrograde movement, so that by October we should be in the same position as we would have been if the scheme had not been in operation.

And Old Age Pensions. Public attention has been called to the matter by the introduction of a Bill into Parliament "to promote the early use of light in certain months of the year"; Mr. Robert Pearce, the member for Leek, being the agent who wishes thus to do us all good by stealth. This gentleman has had to undergo a good deal of good-natured chaff by his unimaginative fellow-legislators, and we should be surprised if so novel a measure found its way to the Statute Book in the course of the next few sessions. But, looked at fairly and squarely, we confess we like the scheme very much, and when hygienic crusades are taking place on all sides it is not for medical reformers to throw cold water on so suitable and elegant a plan for giving health to the people. From every point of view, sunlight is the prime agent of good to man. It supplies him with energy, it tinctures his blood with hæmoglobin, it slays the insidious microbe, and it relieves the strain on his eyes; so much we know, and what good influences lie in its actinic rays we are beginning to find out. Opposition is sure to be forthcoming from gas and electric light companies, whose shareholders, like Demetrius, would be alarmed for the gains of their occupation did the plan look like succeeding; but that would be all the more reason why citizens with no axe to grind should adhere to the other side. It is calculated that the nation would save £2,000,000 yearly by this simple dodge, and if, grateful for the support of the profession, they would use that sum for the supply of old age pensions for medical men over the age of 60, we may assure the promoters that our support would be none the less hearty.

Mrs. Harris à la mode. Even those who are most dissatisfied with the present system of training and "supervising" midwives agree that poor women should have the advantage of being able to secure in their confinements, the services of a person who has had some education in the responsibilities attendant on the practice of the art of obstetrics. The worst of education, however, is that it has a knack of making Jack as good as his master, and despise the daily round and common task which in his unregenerate condition he performed without demur. The old-fashioned Gamp, with all her dirt, and superstition, and ignorance, when she attended a confinement, was not above doing the housework, cooking the husband's dinner, and slapping the children, what time her patron was unable to carry out those necessities of civilised existence. The registered madam of to-day, now that her eyes are opened to the difference between good and evil, considers herself a professional lady, and the position of a domestic drudge is not one which she fancies. At least, so it would appear from a claim made by one Clara Tyte in the Temple Cloud County Court recently. The lady in question sought to recover from a farm labourer the sum of 5s., the balance of the amount alleged to be due to her for attending the defendant's wife in her confinement. The stipulated fee was 10s., but the plaintiff, after attending for three days, was taken ill and had to secure the services of a fellow-midwife, who, like herself was duly certified, to complete the job. The substitute bore the suggestive name of Mrs. Harris, but, unlike her renowned prototype, she was visible in the flesh when duty called. The defendants were not pleased with either of the midwives, and refused to pay Mrs. Tyte for Mrs. Harris's services, alleging neglect on the part of both ladies. These ladies, however, replied that their duties did not include household work, and eventually obtained judgment for 4s. and costs. Surely the old order is changing, but is the new quite Utopian?

The Brown Dog in Parliament. The brown dog has founds its way into Parliament. The Home Secretary was quizzed last week as to the cost of guarding the memorial, and apart from emergency arrangements, it seems that six members of the Metropolitan Police are told off for the sole purpose of watching the statue. Indeed, Buckingham Palace, in all its glory, is not more efficiently cared for, for two sentry boxes have been erected for the accommodation of the policemen on guard, and a sleepless vigil is kept up. The suggestion was made that the cost of these measures should be borne by the Battersea Borough Council, and there seems to be every reason in common sense why they should be. That sapient body have had every opportunity of making reparation for the insult and of withdrawing the obnoxious inscription, but although a temperately-worded motion for this purpose was presented by one of their members and well supported by the more statesmanlike members, the majority would not listen to it, and the proposal was rejected by a large majority. If the Council as a whole, then, consider the inscription worth preserving, they probably will see no reason why it is not worth paying for, and they would probably render themselves very popular with their constituents if they proposed to cast a burden of £700 a year on the rates to gratify their favourite whim of posing as humanitarians and stultifying that honourable title. As things stand, the next move, it seems to us, lies clearly with the Council of University College, who have the public courts open to them, and who should not hesitate to have recourse to them to justify the good name of their institution. Everyone knows ths risks of the law, the chance of a composition of a jury, and the predispositions of the parties engaged, but the accusation is sufficiently specific and definite to afford ground for action, and the College should not fear to attempt victory because of the risks to be taken in achieving it.

Royal Commission on Vivisection. After all it is necessary to remember that the anti-vivisectionists form a very small proportion of the community, although by the noise they create they may be mistaken for a lusty crowd. As a matter of fact, a great deal of the shouting done by them is analogous to that of a child in the dark who makes a noise to show he is not afraid. The influence of the various cliques which run good-hearted people into mistakes and misapprehensions as to experiments on animals is likely to be seriously undermined, we venture to predict, when the report of the Royal Commission on Vivisection comes out. That body has now retired to draft its report, which is likely to be presented in April or May, and seeing the class of people who gave evidence on the anti-vivisection side, their mental calibre, and their general muddleheadedness, we cannot see how the Commissioners can attach any weight to their evidence. The Hon. Stephen Coleridge, with his wild accusations and ingenious methods of treating "facts," cut a particularly pitiable figure when faced with such an impartial judge of evidence and procedure as Lord Selby, before whom bluster and pompous posturing are not calculated to score, as they do on the annual platform of "my" society. We are prepared to see an increase in the inspectorate recommended, for the simple reason that the bulk of the work carried on now is vastly greater than it was thirty years ago, and also as a guarantee to the public that every reasonable precaution is taken. We have no doubt, too, that various points in administration will be subjected to suggestion and criticism, but we shall be surprised if the report is not unanimous, considering the line taken by the various members in examining witnesses.

Indecent Advertisements. We should be glad to know if it has come to the knowledge of any of our readers whether any of their lady patients who have been recently confined, have received obscene advertisements from certain traders. In a case under notice, among the many legitimate advertisements of perambulators and baby requisites which flood the letter-box of parents of a child whose birth has been announced in the daily papers, a particularly offensive circular was received addressed to the wife and marked "Private." Among the announcements of certain trumpery goods purveyed by the firm is contained descriptions of aphrodisiac medicines and preventive pessaries, together with the usual insult to the effect that this sort of thing is supported and prescribed by the medical profession. It is disgusting enough that every dealer in pornographic literature and other filth should advertise "medical specialities" as a description of his prurient goods, but it is more than insulting when the lowest type of quack preparations are described as "recommended by the medical profession." How far the guttersnipe who send advertisements of this type to ladies recently confined are amenable to the law we are not aware, but the matter is certainly one for the police, and we should be glad to place evidence of this kind before them. Indecent advertisements can be no less of a scandal when sent direct to ladies than when published in "comic" papers, and the parties responsible for them should be held equally criminal.

LEADING ARTICLES.

ANOTHER UNITED HOSPITALS CONFERENCE.

MORE than a year has elapsed since the joint Conference of representatives of the medical charities of the United Kingdom met together at University College, London. Our views upon that event were freely expressed in a leading article of the MEDICAL PRESS AND CIRCULAR of December 12th, 1906. The main feature of the situation was a transparent attempt to fix upon the whole hospital system a set of principles framed by persons who, for the most part, were not in close touch with the general practitioner, in whose interests the Conference has been avowedly organised with a view of stemming the tide of hospital abuses. We pointed out that the chairman, although an eminent and a popular man, as an ex-President of the London Royal College of Physicians, represented a body that is absolutely autocratic and aloof from the faintest suspicion of modern democratic thought and progress. The chief resolution, again, was moved by Sir Henry Burdett, an amiable and well-intentioned philanthropist, but, so far as one can gather, without any solid claim to represent the general interests of medical men. The Conference of 1906 was asked to adopt out of hand a number of principles involving most complex and vital issues, and the delegates spoke their minds on these matters with no uncertain voice. They carried a resolution welcoming the further consideration of the principles drawn up by the joint Hospitals Committee of the British Medical Association; they advocated an annual conference; and they appointed a committee to act in conjunction with the Hospitals Committee to consult with medical charities generally and organise a Conference in 1907. The determination to hold a further meeting in 1907 has fallen through, but it is gratifying to find that the germ of energetic hopefulness indicated by the original attempt has been able to survive the perils of its nativity, and that another meeting is to be held in 1908. The composition of the committee entrusted with the organisation of the coming Conference is, we venture to say, hardly that which will secure the confidence of the general practitioner. Take the vexed question of payment by hospital patients, which is one of supreme importance in the relations of the medical charities to the profession. On the committee of fifteen are such ardent advocates of the pay system as Sir Henry Burdett and the Hon. Sydney Holland, not to mention others. Then, again, the lay portion of this united committee has an overwhelming element from the Metropolitant Hospital Funds. With all our admiration of those bodies, it is impossible to shut our eyes to their faults. The government of the King Edward's Fund, for instance, is absolutely autocratic, and the representative element is either absent or hopelessly curtailed. The policy of the Sunday and the King Edward's Funds is clearly to destroy the small hospitals, and their awarding or withholding of public money is determined upon *in camerâ*. There is no opportunity for an aggrieved hospital to appeal against a decision or to ascertain the reasons for a grant having been withheld. Under such circumstances the dispensation of money entrusted to the Funds for distribution is practically handed over to a kind of Twentieth Century Star Chamber, of which the administrators and defenders are amiable and benevolent elderly gentlemen whose only conceivable ulterior motive could be the somewhat meagre one of love of power and the thirst for social advancement. Now, if the United Kingdom Hospitals Conference Committee, as it is now called, wants to submit a vital issue at their meeting, let them bring forward the policy, the administration, and the control of the Metropolitan Hospital Funds. If these things be settled on a sound basis in London the rest of the kingdom will quickly follow suit. The Funds are claiming the right by the power over the purse to direct the affairs of the metropolitan hospitals. This assumption may, or may not, after due discussion, meet with general approval. But the public will demand a declaration of the principles which are adopted by the Funds. Are the Funds, for instance, in favour of the pay system by patients, or are they not? Do they uphold any system of restricting the number of patients seen by the honorary medical staff? Are they to be supported in their deliberate policy of crushing the small hospitals out of existence? Why should not the Funds seize the opportunity of this Conference, pregnant as it is with possibilities for the future progress of the cause of the medical charities, to declare their views upon each of the fundamental principles to be discussed at the Conference? Surely, if the Funds are to be the self-appointed mentors of the hospitals, their minds should be made up on all these points. If they are not so made up, how can the public and the medical profession and the medical charities look forward to consistency and justice in the allocation of money given by the charitable for the relief of the suffering poor? At present the policy of the Funds appears to be simply chaotic, and lies at the mercy of the caprice of irresponsible individuals or small groups of individuals. At the present moment there is a widespread feeling of discontent against the arbitrary actions of the King Edward's Fund, and we suggest that the Fund will do well to approach the Conference, and by that conciliatory step to avert the possibility of a coming storm. As regards the Conference itself, we have little doubt that the representatives will have the courage of their opinions in 1908 as they had in 1906, and that they will refuse to be guided by any but their own convictions. The issues are of importance, not only to the medical profession, but also to the public. Moreover, ultimate settlement can only be arrived at on sound and equitable principles, but the evolution of perfection in human affairs is often an extremely slow process. At any rate, whether we agree or otherwise with the views of the organisers of the original Conference, we thank them most heartily in the name of the medical profession for the attempt to arrive at some sort of solution to the many problems that vex the hospital world. That they should have survived the somewhat serious rebuff of 1906, and have presented a revised programme for discussion in 1908, furnishes a proof of tenacity of purpose that augurs well for the future. They have practically accepted the only sound basis of permanent rule, namely, government by consent or representation of the majority. If we mistake not, the real struggle to be fought out at the second Hospitals Conference is that between the autocratic and the representative government of hospital funds, of hospitals, and of the medical profession.

THE HEALTH OF DUBLIN.

Dublin is, as our readers are aware, the city with the highest death-rate in the kingdom. During the ten years 1895-1905 its average annual death-rate was 27 per 1,000, as contrasted with that of London, 17.7 per 1,000, and of Edinburgh, 16.7. During the past few weeks the mortality rate of the Dublin Registration Area, which contains several healthy suburbs as well as the City of Dublin, has reached to 30 and even 33 per 1,000 per annum, the city rate being presumably something higher. It will be seen, therefore, that Dublin has an unenviable eminence, not only in the United Kingdom, but throughout Europe. As a matter of fact, outside some of the cities of Russia, we can find no city in Europe whose average mortality is as high as that of Dublin. These facts are so notorious that one might hope that the Corporation of Dublin would have been forced by very fear to bestir themselves to do something to put the city in a more healthy condition. It will hardly be believed that Dublin, a city with over a quarter of a million inhabitants, and the appalling mortality we have mentioned, has not the advantages of the services of a whole-time medical officer of health. Such, however, is the case, and, moreover, in the health department there is not a single qualified assistant. In the year 1900 a Committee appointed on the suggestion of Earl Cadogan, then Lord Lieutenant of Ireland, to inquire into the causes of high mortality in Dublin, made in their report some eighteen recommendations. Of these, according to the report of Surgeon-Colonel Flinn to the Local Government Board a year ago, four have been followed. The excuse given for the neglect of most of the remainder is, that new legislation is necessary to carry them into effect. This requisite legislation the Dublin Corporation are now in a position to demand, as they are promoting an Omnibus (or Various Powers) Bill in the present session of Parliament. As first drafted and submitted to the House, this Bill contained clauses which would give the Corporation much valuable power to deal with matters affecting the public health. Provision is made therein for the compulsory notification of tuberculosis, for the establishment and maintenance of a bacteriological laboratory, for the better control of meat and milk exposed for food, and for the establishment of milk depôts. To our amazement, however, it is now proposed to drop these sections! Vested interests have apparently been too strong, and the Bill has been eviscerated. As a measure for the betterment of public health, it will not be worth the paper it is printed on, except for the solitary clause making it a penal offence to spit in a public place! We do not know how long the public of Dublin is going to tolerate this criminal contempt for their lives. If the Corporation of Dublin persist in the withdrawal of the public health clauses, they are taking on their heads the responsibility of postponing indefinitely the public health reforms so urgently required.

CURRENT TOPICS.

The Professional Income.

THE editors of some of the public newspapers have lately been exercised in mind as to the general prosperity of the medical profession. They have been set thinking by the fact that large numbers of highly-qualified men apply for any vacancy in a public post offering a salary of £500 a year. The idea of a man in the prime of life, who has spent several thousand pounds and devoted many years of his life to render himself competent in a learned profession striving for such a post as his *summum bonum,* may well make the average journalist pause. What moderately prosperous tradesman would launch his son on the journey of life with such a prospect as that before him? Yet the average medical practitioner would think himself lucky if he can made sure of an income of £500 after years of honourable and assiduous toil. The fact may be commended to Mr. John Burns and other legislators who appear to think that the State is entitled to demand gratuitous services from the medical profession. A close review of the situation, however, will serve to show the editors that they themselves have no small hand in straitening the medical income. Without newspaper advertising there would speedily be an end of the huge system of quackery which now defrauds the public and diverts them from the honourable services of State-qualified medical practitioners. The public suffer not only in health, but also by the injury inflicted upon their medical attendants—while the newspaper proprietors, and their advertising clients, prosper exceedingly.

Report on the Peterhead Typhoid Epidemic.

THE report on the recent epidemic of enteric fever at Peterhead has been presented by Professor Matthew Hay to the local Town Council. Some interesting points were brought forward. The sanitary arrangements of the town are clearly open to a good deal of improvement, especially in the provision of water closets and of sound drains. The origin of the epidemic, moreover, lay neither in the water supply nor in the defective drainage, although the water supply appears to be in need of rigorous remedial measures even more than the drainage system. It is exposed to risks of contamination at many points, and the catchment area of its origin contains various dairy farms manured with town refuse. So that if Peterhead has not been devastated by wholesale typhoid fever, it seems to be rather by good luck than by good management. The ultimate cause of the outbreak was an infected milk supply, and the later spread of the disease was for the most part due to personal contact. Peterhead has now had a formal warning, so to speak, to put its house in order, still it is somewhat disquieting to learn from Professor Hay that in the matter of defective drainage Peterhead is probably not worse than the majority of towns of similar size and age. Like all other reforms, that of sanitation makes but slow headway against the inertia of the established and conservative order of things.

Herbal Indignation.

THE Bradford and Halifax Branch of the National Association of Medical Herbalists, Limited, held a monthly meeting last week, to enjoy a scientific paper by a member on "The Evil of a Common Cold," but the lecturer being summoned suddenly away, presumably to attend some patient with whom his herbs were not agreeing, the members fell to politics as affecting their cult. Ultimately a number of resolutions were passed *nem. con.* The first urged the Council of the Association to take immediate steps to get some definite provision for *bonâ fide* medical herbalists under the Death Registration Act, "in order to avoid the worry and anxiety their patients are put to." The second was like unto it, namely, that a strong protest be laid before the Lord Chancellor against holding inquests on the patients of herbalists, except under extraordinary circumstances, and finally that the testimony of the herbalists themselves should be taken at inquests. The herbalists are beginning to take themselves very seriously, and their desire that the deaths of their patients shall not be made the subject of inquiry is very natural. The exposure attendant thereon must certainly be bad for trade.

The Local Government Board and Plural Appointments.

IN former years the general undesirability of plurality in public health appointments has been adversely criticised in our columns. It is only under the most exceptional circumstances that any single medical officer of health or analyst can do justice to more than one appointment, especially if it be of any great magnitude and importance. We are glad to see that the Local Government Board has taken up this point, because, after all said and done, the key to the situation has been ultimately in the hands of the central authorities at Whitehall. The immediate occasion of their interference was the proposal to appoint Dr. G. P. McCleary, Medical Officer of Health for Hampstead, to the post of Consulting Medical Officer of the Bedfordshire County Council. As the Local Government Board pay half this salary they have a right to withhold their consent, which they have done on the ground that under the terms of the present appointment he is bound to give the whole of his time to the service of the Hampstead Borough Council. It is to be hoped that this policy will be definitely established at Whitehall, for in some instances that could be cited the number of diverse posts held by individual health officers amounts to something approaching a public scandal. Amongst other serious objections to plurality of posts is that it tends to encourage underpayment of officers by local authorities, who regard the added posts as contributory sources of income which will ease their own legitimate burden.

The Viewing of Bodies.

THE English law is built upon tradition, and many of its survivals have long since become grotesque. Now and then, as in the case of the proclamation of the court usher, "O Yes, O Yes," there is a quaint reminder of ancient times that reconciles one to its want of latterday practicability. Undoubtedly, it appeals more forcibly to the imagination of the man in the street to call for his attention in corrupt Norman than in simple Anglo-Saxon. Other legal survivals, however, are injurious to the best interests of the subject, and should be relegated to the limbo of barbarous times. Among these objectionable things may be mentioned the "viewing" of the body by the Coroner's jury. In ancient times, somewhere about the Norman Conquest, the Coroner's jurisdiction gradually emerged into separate existence, and it has been with us ever since. In the early days when the general security of life and property was a plant of slender growth, it was undoubtedly necessary to ensure identification of a body found dead by every reasonable means at command. But it would be idle in the present day to say that the Coroner's jury are able materially to assist the cause of justice by personal inspection of the corpse. On the other hand, the process is sometimes dangerous and often revolting. A Bill will shortly be read a first time in the Commons, introduced by Mr. Higham, to dispense with the compulsory viewing of bodies by Coroners' juries. Under exceptional circumstances we imagine the right to compel viewing would probably be retained by the Coroner.

Fees of Medical Witnesses.

WHILE so much is heard nowadays about the hard case of the medical practitioner, it cannot be said that the authorities, great or small, neglect any opportunity of cutting down his income still further. On this principle the Lancashire County Council recently decided that after March 31st they will pay only one guinea per inquest to medical men giving evidence Mr. Coroner Brighouse, of South-West Lancashire, referring to the subject the other day at St. Helens, suggested that the doctors should protest most vigorously. No doubt this advice will be followed to the letter by the local medical societies. It is to be hoped that the matter will go further, and be taken up by the British Medical Association and by other medical journals, for this parsimony affects the whole profession. As a matter of fact, some unfortunate practitioner in Lancashire may find himself taken a long distance away from his patients and kept waiting two or three days to give evidence, for which he will be awarded the magnificent sum of one guinea. Well might Mr. Brighouse exclaim that if he were a medical man he would never dream, under the circumstances, of bringing his son up to the profession to which he belonged; he would rather make him a crossing sweeper! We trust his fervent wish will be realised, namely, that medical men will take steps to see they were remunerated in a manner that is more consistent with the knowledge they bring to bear on the execution of their duties.

PERSONAL.

DR. D. J. MORGAN, M.A., M.D. Cantab., D.P.H., has been appointed Medical Officer of Health for the Borough of Swansea.

SIR ALMROTH WRIGHT will deliver the Harveian Lecture on "Some Points in Connection with Therapeutic Immunisation."

SIR HENRY R. SWANZY, President of the Royal College of Surgeons of Ireland, took the chair at the annual dinner of that institution on February 1st.

DR. GLOVER LYON was elected President of the Life Assurance Medical Officers Association on February 6th, and delivered his Presidential Address.

MR. D'ARCY POWER has been elected President of the Harveian Society, Mr. Crisp English and Dr. Willcox being elected Honorary Secretaries.

DR. R. B. WILD has been unanimously elected Chairman of Convocation of the University of Manchester.

DR. WILFRED HARRIS has been appointed Physician-in-Charge of the new special department for nervous diseases at St. Mary's Hospital.

MR. W. J. M. ETTLES will give the annual Hunterian Oration to the Hunterian Society this evening. His subject is "The Renaissance of Ophthalmology during the Hunterian Period." Medical men are invited.

DR. W. CARTER has been appointed a Professor Emeritus, in recognition of his long and useful services to the Liverpool University College and the University.

ON February 18th Sir Dyce Duckworth will give a lecture in French to the Medical Faculty of Paris on "Les Diathèses, le Facteur Personnel dans les Maladies." Professor Landouzy will be in the chair.

DR. W. N. BARLOW, who was for six years Medical Officer of Bootle, and now holds a similar post under the Wallasey District Council, was the recipient of two handsome presentations from his old colleagues under the Health Committee of Bootle.

DR. CHARLES PYE OLIVER has been appointed by the Borough Council of Maidstone to carry out the medical inspection of school children. For services rendered in this connection his salary has been raised by £200 per annum.

THE Liverpool Council last week passed a special resolution of thanks to His Majesty for his gift of a plaster cast of his horse Persimmon to the Veterinary Department. The school is fortunate in the possession of the skeleton of his Majesty's horse Ambush II., presented some time ago, and also of the skeleton of the well-known steeplechaser Manifesto.

A CLINICAL LECTURE

ON

CANCER OF THE UTERUS. (a)

By CUTHBERT LOCKYER, M.D., B.S., F.R.C.S.,

Senior Out-Patient Physician, Samaritan Hospital for Women; Obstetric Physician in Charge of Out-Patients, Great Northern Hospital.

Gentlemen,—I have chosen to speak upon the somewhat melancholy subject of cancer of the uterus, because it is one which has occupied and engrossed my thoughts for many years, and because I am sure that no one who listens to what I have to say can dispute the fact that it is a subject of prime importance for us all. It is now a well-established fact that more women die of cancer of the womb than of cancer of any other part of the body. As Dr. Herbert Spencer reminded us in his admirable address at Exeter last July, nearly 4,000 adult women die of cancer of the uterus every year in England and Wales. This is an appalling fact; and in these days of surgical successes it behoves us to ask ourselves what can be the causes which lead to so sad a record.

The main reason is not far to seek. The women come to gynæcologists too late for operation. Then, again, many operators are themselves very pessimistic, and have as little to do with cancer of the uterus as possible. Dr. Spencer quotes Pozzi as saying he cannot speak of cure by operation, but only of "prolonged survivals"; but when we remember that there are many cases on record where women have remained well for twenty years after operation for cancer of the cervix, it is certainly not going too far to say that, under favourable conditions, this disease can be cured by operation. As an operating gynæcologist, I am convinced that if cases come to me early in the disease, I can honestly promise a fair measure of successes, and what I would like to insist on, to-day and for all time, is that we operators need the intelligent co-operation of our brethren, the general practitioners (to whom many of these sufferers from cancer first present themselves). An immediate examination should be insisted upon, and in cases of even doubtful malignancy a microscopical examination should be made of the suspicious cervix, and this can only be done for the poorer classes in an hospital.

From a careful record of every case of cancer of the uterus which has come under my observation, I have calculated that from the vaginal hysterectomy point of view, at least 80 per cent. were inoperable when first seen. For the last two and a half years I have abandoned this operation for the more radical method of abdominal pan-hysterectomy according to Wertheim's technique, thereby raising the percentage operability almost fourfold. Whilst mentioning this fact, I would fain point out my conviction that the improvement hoped for in dealing with cancer of the uterus is not to be sought so much in extended operative technique as in an hitherto un-made effort to get these cases in the initial stages of the disease. Strenuous attempts must be made to educate the patients, general practitioners, midwives, and all concerned in the signs and symptoms of incipient cancer; and the question arises—How is this to be done? Five years ago Winter published a paper entitled "Strife Against Uterine Cancer," in which he stated the results obtained from a pamphleteering crusade which he waged single-handed in East Prussia. In addition to soliciting the help of general practitioners, midwives, and irregular practitioners, he utilised the medium of the public Press, advertising far and wide the symptoms of early carcinoma of the womb.

Professor Strassmann, of Berlin, who was present at the discussion on the earlier recognition of cancer opened by Dr. Spencer at Exeter, laid on the table a specimen of the appeal issued by the Berlin Society of Obstetrics and Gynæcology to practitioners in that city, asking for their help in the campaign against cancer. He told us that the same Society issued pamphlets instructing midwives in the early symptoms of cancer, and Strassmann advised that popular lectures should be given to the public, even going so far as to advocate a demonstration to the laity of specimens such as we have before us to-day. The consensus of opinion at the Exeter meeting was in striking contrast to that expressed at the Leicester meeting of the British Medical Association in 1905. The idea of educating the public by any means whatever met only with derision two years ago, whereas at Exeter last July Dr. Thomas Wilson's amendment, "That the Council of the British Medical Association be requested to appoint a Committee to consider the best means of disseminating knowledge of the importance of the early recognition of uterine cancer," was carried *nem. con.*

We have a right to hope, therefore, that some sort of crusade will soon be started in England, and it is to be hoped that the Registrar-General's report of 4,000 deaths annually from cancer of the womb will be substantially reduced.

Whilst awaiting the inauguration of a scheme of crusade by the British Medical Association against cancer, it will not be amiss to pass in review the signs and symptoms by which we as doctors are to recognise the disease.

In the first place, let us remember that cancer of the womb varies greatly in degree of malignancy, according to whether it originates in the body or in the neck of that organ.

Cancer of the "body," whether it be the type known as malignant adenoma, or whether it be the diffuse adeno-carcinoma, is far less virulent than is any form of cancer affecting the cervix. Cancer of the body is a rarer disease than cancer of the cervix. It is generally found in elderly spinsters, or in elderly married women who have borne but few children.

It arises more commonly after the menopause than before the change of life.

Its connection with the lymphatics and blood-vascular system of the pelvis is less intimate and more remote than is the case where cancer starts in the neck of the womb. Consequently, there is far less risk of the growth trespassing beyond the confines of the uterus than is the case with carcinoma cervicis. This disease may be suspected when a sanious discharge makes its appearance after the menses have totally ceased, or where an inter-menstrual, blood-stained, watery discharge is noticed in a previously healthy woman about the time of the climacteric.

It may exist in a uterus which is atrophic from old age, and which gives a sound-measurement of less than 2½ inches. I have had three examples illustrating this fact, where the uteri were small and mobile, painless on contact by bi-manual examination, and where nothing wrong could be discovered, save the fact that the patient had a blood-stained discharge.

On the other hand, a corporeal cancerous growth may be rapid in its development, enlarging the uterine body to three or four times its normal size in a short time.

The treatment for these cases, in my opinion, is vaginal hysterectomy, but the abdominal route is the better if there is stenosis or contraction of the vagina.

I do not favour vagino-perineal section in these cases, for several reasons. First, because, even when the vagina and perineum have been split to give freer access, it frequently happens that, before the uterus can be removed, the organ has to be divided by mesial section, which leads to direct cancer implantation upon the newly-cut surfaces; and, secondly, in drawing down a uterus per vaginam, the cancerous material is very prone to ooze out through the external os, even when attempts have been made to close the canal by circular ligature. With plenty of room, however, we can remove a small uterus with cancer of the body, *per vias naturales*, with perfect safety. I have removed the uterus seven times for cancer of the body with one recurrence. One case dates back five years, and the woman has had no return of the disease. The recurrence occurred in my third case, and appeared within a few months of operation, the site of the secondary growth being the urethra. The body of the uterus was large, and I think the urethral orifice was abraded by the vaginal speculum.

(a) Post Graduate Lecture delivered at the Great Northern Central Hospital, Jan. 31, 1908.

To pass to the more important question of cancer of the cervix, let us first note that this commoner and more fatal disease is prone to affect the mothers of large families. In Lewer's statistics, he proves that women who have borne five children are more liable to become the subjects of this malady than those whose families are smaller. As regards the age incidence, cancer of the cervix is commonest between 35 and 50 years, but is by no means confined to these limits, so that the age question must not be allowed to weigh in the least against the diagnosis of cancer of the cervix. Heredity is thought to play a not unimportant *rôle* by some, but my own experience leaves this an open question.

Among the early symptoms, *bleeding* is the most important indication; in fact, for some time it may constitute the only sign. In some of my cases the bleeding has amounted to a flooding or floodings, but, as a rule, a pinkish *discharge* and hæmorrhage of slight degree, only noticed on coitus, constituted the earliest symptom. The early hæmorrhage is often preceded or accompanied by a muco-purulent discharge, the latter being streaked with blood, and at first not offensive. Later on, *pain* is added to the above cardinal signs, and, unfortunately, the patient often postpones her visit to the family doctor until this late symptom has driven her to seek advice. The pain is often associated with fœtor from necrosis and decomposition of the growth.

The pain may be due to extension of the growth into the cellular tissues which embrace the cervix, or it may be caused by distension of the cavity of the uterus by discharges which cannot escape because the cervical growth has completely blocked the cervical canal. The physical signs of cervix carcinoma are worthy of careful study, and in this connection I would state that, whilst some cases could not be missed by a novice provided he made vaginal examination, others are extremely difficult of diagnosis in the early stages, and in these the microscope is often necessary to settle the question.

When cancer of the cervix presents as a prominent excrescence or overgrowth, or where it takes the form of an excavating ulcer which bleeds profusely on digital examination, there can be no doubt about the nature of the case. It is with what are termed intra-cervical growths that a difficulty may arise. Here there may be no abrasion of the vaginal surface of the cervix, but only a circumferential enlargement of the collum or an induration or thickening of one or other lip. In such a case it is well to pass a sound into the cervical canal to see if there is any bleeding, for the external surface of the cervix will not bleed on contact. In such cases the os is usually patulous, the canal bleeds readily on passing a sound, and the cervix is thickened.

Again, a simple erosion may take on malignant activity, and for this reason erosions should not be ignored, but carefully treated and examined until healing is secured.

My plan in dealing with erosions of the cervix is to pass a Fergusson's speculum, mop away all discharge with a solution of bicarbonate of soda, then swab the surface with iodised-phenol, remove the excess, and insert a tampon soaked in 10 per cent. ichthyol in glycerine. This I do every week until the lesion is healed.

If the erosion shows any signs of spreading, or is sluggish under treatment, I remove a portion for microscopical examination. This is done under anæsthesia, when the nature of the tissue can be better studied, and at the same time I apply the actual cautery to the so-called ulcerated area.

These are the precautions which I should like to feel were becoming generalised, for I am sure many lives would be saved, for, speaking generally, it may be said that it is only in the early stages that cancer of the cervix is difficult of diagnosis, and it is equally true that only in the early cases can we feel any degree of certainty as to permanent cure by operation.

There are but few affections of the cervix which can be confused with cancer upon making a thorough vaginal examination. The most likely condition is primary tuberculosis. A colleague of mine sent me a case which he considered might be tuberculosis, but which proved to be cancer. I have seen two or three examples of tuberculous cervix after removal, but have never met with a case in the ordinary course of vaginal examination. Again, the microscope will tell us with which of the two diseases we have to deal.

The danger of cancer of the cervix is twofold: The disease soon spreads by continuity of tissue to the surrounding parts; it is also prone to cause early infection of the lymph glands of the pelvis.

A point of practical importance is that, whereas under anæsthesia we can, with some degree of accuracy, estimate the freedom or otherwise of the parametric tissues, such as the bases of the broad ligaments and the utero-sacral folds, it is extremely difficult to feel the cancerous glands which run along the great iliac vessels, and which lie deep in the fossa ovarica. Only once have I been able to feel these glands, and in this case a well-known Colonial gynæcologist thought the palpable mass was an enlarged ovary.

The frequent gland-involvement, and the more frequent infection of the parametric tissues, even in cases of comparatively small malignant growths of the cervix, have an important bearing upon the question of operative technique, and, to my mind, render any hope to secure a large percentage of permanent cures by vaginal hysterectomy quite abortive. In the year 1902 I expressed my doubts, at a meeting of the Obstetrical Society of London, on the utility of vaginal hysterectomy as a radical operation for cancer of the cervix. My objections to this operation are not theoretical, but based upon personal experience—an experience which I have published *in extenso* in the *British Medical Journal.* Vaginal hysterectomy opens up the enormous risk of implantation of cancer cells on the surfaces which are severed during operation, so that in a large number of the cases so treated this growth returns locally in the vaginal vault. Moreover, it is impossible to remove the parametric tissues which surround the cervix when operating per vaginam, whilst, of course, the high-lying cancerous glands are not discoverable, and, if they were, could not be removed. It seems high time that we should adopt a more heroic technique in dealing with this fatal disease, and science, as well as humanity, demands a more determined effort to cope with cancer of the cervix on the lines of modern surgery, such as is exemplified in dealing with malignancy in other parts of the body. We see the general surgeon attacking cancer of the breast by following the lymphatics on to the abdominal wall, into the axilla, and even beneath the clavicle and up the neck; and yet English gynæcologists have been content to palliate with cancer of the cervix by leaving the infected adjacent tissues behind. The reason for this seems to me to be the fact that there are admittedly some cases—although few—in which the patients have remained well after amputation of the cervix and vaginal hysterectomy for eight, twelve, and even twenty years; but it cannot be denied that these are the fortunate exceptions which prove the rule—the rule of almost complete and total failure. I abandoned the vaginal operation in 1905. I had performed hysterectomy per vaginam for 14 cases of cancer of the cervix. In nine cases the patients died of recurrence, and one has been lost sight of, so that only four can be proved to have benefited by my exertions.

Whilst despairing of getting any satisfactory results by vaginal hysterectomy, I had the good fortune to meet Professor Wertheim, and to learn from him his method of abdominal pan-hysterectomy. Wertheim was generous enough to operate, with my assistance, upon a case of my own in London, and subsequently I studied his method by watching his technique in Vienna, and I am sufficiently impressed by its superiority over every other method of dealing with cancer of the cervix to have decided to burn my boats behind me as far as the vaginal operation is concerned, and throw my lot in with Wertheim for the future.

An outline of Wertheim's technique is as follows:—The patient is prepared for abdominal section. She is then placed in the lithotomy position, and, without an anæsthetic, the growth is scraped away as thoroughly as possible, and the bleeding surface then treated with the actual or Paquelin's cautery. The vagina is then plugged with tampons soaked in a 2 per cent. formalin solution, and carrying strings by which they can be withdrawn during the operation at the time desired. Next the patient is anæsthetised by a general anæsthetic, or partial anæsthesia is secured by lumbar puncture, and the introduction of stovain into the canal of the spinal cord. The high pelvic posture is used, and two assistants are employed. The abdominal incision is at least five or six inches long, and extends to the bony symphysis. The parietal peritoneum is divided down to the fundus of the bladder. No retractors are employed; the second assistant retracts by both hands; no gloves are used. The fundus uteri is drawn up as far as possible and inclined over the anterior pelvic brim, where it is held by a vulsellum. The posterior fold of the broad ligament on the side opposite the operator is seized by dissecting forceps, and opened about 1½ in. below the Fallopian tube. By closed blunt scissors the two folds are separated from one another, and the ureter sought, as it lies in close apposition to the posterior fold. It is then followed back to its point of crossing the pelvic brim, and forwards to its entrance into a fibrous canal by the side of the cervix. The index finger of the hand corresponding to the side operated upon is then introduced into this canal, and the later dilated, whilst the finger is made to come out of the canal at a point anterior to the cervix. To expose the finger-tip it is now necessary to strip off the anterior fold of the broad ligaments which obscures it from view, and at the same time—if it has not been previously done—the infundibulo-pelvic fold must be tied off, the meso-salpinx divided, and the round ligaments tied and cut. This enables the operator to see the structures which lie upon his finger as the latter passes through the ureteric canal. They are the uterine artery and veins. These are hooked up by the finger, and a ligature is now passed beneath them, and they are tied far out against the pelvic wall.

When this is done the ureter lies exposed as far as within an inch or so of its entry into the bladder. The latter is now freed from contact with the uterus and vaginal wall, and by a little dissection the ureter can be exposed right up to its entrance at the corner of the trigone. The same procedure is carried out on the opposite side, and then the peritoneum and rectum are stripped from off the posterior wall of the cervix and vagina. Next the ureters are held well aside whilst the utero-sacral, parametric, and para-vaginal tissues are clamped. The tampons are removed from the vagina after the latter has been dissected out far enough to apply the clamps beyond the cervical growth. This done, the vagina itself is cut across beyond the clamps. The uterus, with the collar of dissected vagina, securely clamped beyond the growth, is then removed. The edges of the vagina are held open by a series of long silk sutures; the canal is cleansed by swabbing, the edges ligatured, and finally all clamps are replaced by ligature. Glands are now sought for. and, if found, removed. Before closing off the deep raw surfaces by peritoneum, Wertheim packs them fairly firmly with gauze, the end of which passes into the open vagina. No abdominal drain is ever used. I have modified many details in this technique to suit my own ends. I do not use gauze, but leave the tissues to drain of themselves. I do not scrape the growth without an anæsthetic, but carry out this procedure a week before I remove the uterus. I prefer to keep my patients in bed for ten days or a fortnight on strychnine prior to the final operation. In drawing up the uterus I free the round ligaments, meso-salpinges, and infundibulo-pelvic folds before looking for the ureter. In cases of old pelvic inflammation, where the tubes and ovaries are diseased, if the ureter is not easily found behind the uterus I endeavour to discover it first in front.

I pass a sound into the uterine body at the time of scraping and cauterising the growth in order to determine the presence or absence of a pyometra. I sew the peritoneum to the skin all around the parietal wound in order to shut off raw surfaces and protect the cavum Retzii. I wear gloves, employ but one assistant, and use my own automatic retractor. For the rest I use Wertheim's special instruments—his parametric forceps and vaginal clamps.

In July I reported 12 cases in which I had performed this operation. All save two were too far advanced for vaginal hysterectomy. My primary mortality was four, and two cases have died of recurrence. Since July I have performed the operation three times, and all the cases did well.

There is a higher primary mortality with this operation than is obtained by the old vaginal method, but against this must be placed the fact that four times as many cases can be dealt with by abdominal pan-hysterectomy than by the vaginal route.

Speed in operating and a thorough knowledge of the deep pelvic structures are most essential factors to success. I have every reason to believe that my high initial mortality will not continue, as the practice gained of experience makes every operation more easy of performance. In conclusion, gentlemen, let me say that I hope much from this operation of Wertheim's, since Wertheim's own statistics are better than those of any other operator which have hitherto been published.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by J. Dundon, M.B., F.R.C.S. Eng. and Irel., Surgeon, Mercy Hospital, Cork, Senior Assistant Surgeon, North City and County Infirmary, Cork. Subject: "Diagnosis of Injuries above the Shoulder."*

ORIGINAL PAPERS.

A SHORT SUMMARY OF LITERATURE OF

LUMBAR PUNCTURE IN OPTIC NEURITIS.

By SYDNEY STEPHENSON, M.B., C.M.,
Ophthalmic Surgeon North-Eastern Hospital for Children, London, etc., etc.

BABINSKI and CHAILLOUS.—The therapeutic results of lumbar puncture in optic neuritis of intra-cranial origin. (Résultats thérapeutiques de la ponction lombaire dans les névrites optiques d'origine intra-cranienne.)

Bull. et Mém. de la Société Française d'ophtalmologie. XIV., 1907, p. 302.

Babinski and Chaillous preface an important communication on the therapeutic results of lumbar puncture in optic neuritis by a brief reference to the work done by Druault, de Lapersonne, Aubineau, Moissonnier, and Abadie respectively in this direction. The authors next relate seven cases where improvement followed the operation,. In abstract, the leading facts of these cases are as follows:

CASE NO. 1.—*Disturbances of sight after a fall on the head. Lumbar puncture. Cure.*

Five weeks after a fall upon the head, an accident followed at once by unconsciousness and emesis and later by violent headache, the patient found that his sight had failed (R.E., 12 opt.; L.E., 9 opt.).

The failure of the sight was due to intra-cranial pressure. After the removal of 15 c.cm. of cerebro-spinal fluid by lumbar puncture, the headaches almost disappeared, and the sight of the left eye rose to 11 opts. The optic discs, moreover, had become almost normal. Somewhat later, the patient, apparently cured, was able to resume his occupation, that of a lithographer.

Case No. 2.—*Bilateral optic neuritis. Paralysis of the right external rectus. Lumbar puncture. Cure.*

A married woman, æt. 23, suffered from headache, paralysis of one external rectus muscle, and bad sight due to bilateral papillitis. Lumbar puncture was followed in seven days by some modification for the better in the ophthalmoscopic appearances. A second and third operation were succeeded by disappearance of diplopia, and eventually by cure. Other treatment included seven or eight intra-muscular injections of calomel.

Case No. 3.—*Bilateral œdematous neuritis with considerable diminution in the sight of the left eye and blindness of the right eye. Lumbar puncture. Rapid improvement.*

A man, æt. 19, admitted for intense frontal headache, vertigo, asthenia, vomiting, constipation. After lumbar puncture, headache completely disappeared, and the other symptoms became attenuated. Three days after the little operation, however, the man complained that he had suddenly become blind in his right eye, and that the vision of the left eye was dim. There was intense optic papillitis. A second lumbar puncture, together with mercurial treatment, was slowly followed by considerable improvement in sight. The optic discs, however, became pale. When seen nine months after admission, vision had risen to 0.7.

Case No. 4.—*Bilateral optic neuritis. Paralysis of the left external rectus muscle. Syphilitic meningitis probable. Lumbar punctures. Rapid disappearance of the papillitis.*

A woman, æt. 24, who had probably acquired syphilis, was received suffering from defective sight, vertigo, and gastric disturbances. On examination, bilateral papillitis and paralysis of the left external rectus muscle. Visual acuity and visual fields normal. Marked lymphocytosis in cerebro-spinal fluid obtained by lumbar puncture. The operation was followed by diminution in the vertigo and definite improvement in the state of the optic discs. The woman, however, had also received a daily injection of mercury biniodide. Another puncture was succeeded by further improvement in the neuritis and disappearance of the diplopia, although by careful examination with a coloured glass, the external rectus was found to be still paralysed. The latter, however, disappeared a week later. In the further history of the case the patient developed hemiplegia, without premonitory symptoms.

Case No. 5.—*Bilateral œdematous neuritis. Paralysis of the left external rectus muscle. Lumbar puncture. Rapid improvement in sight and visual field. Reduction in the symptoms of intra-cranial pressure.*

A man, æt. 20, was admitted on account of severe headaches, vomiting, vertigo, delirium, diplopia, and defective sight. The family history suggested syphilis. On examination, frontal headache, especially at night, obstinate constipation, marked asthenia, emaniation, and paralysis of the left external rectus muscle. Bilateral optic neuritis. R.V., 1.50–50; L.V., 5–30. Ten minutes after the withdrawal of 25 c.cm. of cerebro-spinal fluid, R.V. 5–15 and L.V. 2.50–50, while the visual field in each eye had increased in size by 10° (average). Iodide and mercury were then administered. The treatment was followed by eventual disappearance of the optic neuritis and diplopia and by vision of 5–30. A relapse took place in the course of about six months, and the man, who had meanwhile enlisted, was lost sight of soon afterwards. The last note of sight was 5–15.

Case No. 6.—*Bilateral optic neuritis. Lumbar puncture. Considerable but transitory improvement.*

A female, admitted on account of headache, accompanied by disturbance of sight and of hearing. Double optic neuritis, V. 5–10. A week's treatment by injections of calomel having failed to improve matters, lumbar puncture was resorted to. Abundant lymphocytosis. Sight tested immediately after the operation had risen to R. 8–10 and L. 9–10. About a month after operation a note was made to the effect that the optic discs were also normal in appearance. But despite calomel injections, the vision fell again, the right trigeminal nerve became affected, and the patient was lost sight of some four months after she was admitted.

Case No. 7.—*Hydrocephalus. Lumbar punctures. Arrest of the symptoms of compression.*

A child, æt. 1, brought on account of hydrocephalus. Optic neuritis had been found in the child eight months previously. On examination, post-papillitic atrophy of both optic discs. Four lumbar punctures were made in the course of three months. No lymphocytosis. In the result, ocular and general condition of the child improved.

Case No. 8.—*Cerebral tumour. Bilateral optic neuritis. Arrest lasting for several months.*

In May, 1904, one of the authors was consulted by a patient on account of right hemiparesis, complicated with disturbance of speech, believed at the time to be due to softening (*ramollissement*) of the psycho-motor area of the left cortex and of Broca's convolution. During the next three months, Jacksonian epilepsy involving the right side (face, upper and lower extremity). Mercurial treatment adopted. By the following December the patient's condition had become worse. Surgical measures not adopted since the absence of headache, vomiting, and optic neuritis was thought to tell against the existence of a cerebral neoplasm. The mercurial treatment was continued. But in October, 1905, double optic neuritis was found to be present. Between that month and May, 1906, seven or eight lumbar punctures were practised, the fluid on each occasion being normal. On the whole, the ocular symptoms improved during this period. In May, 1906, the optic neuritis became more pronounced and the sight suffered. In the following month (June) the patient was trephined, and a tumour, weighing 310 grammes, was excochliated from the motor area. The patient unfortunately died in syncope as soon as the operation was completed.

Babinski and Chaillous advise that in performing Quincke's operation, the following precautions be observed:—(1) The patient should be recumbent; (2) the cerebro-spinal fluid should be evacuated slowly, drop by drop, and a maximum of 8–10 c.cm. should at the most be removed; (3) after the operation the patient should be kept in bed for several days. They conclude that lumbar puncture may be considered as a curative method in optic neuritis due to intra-cranial effusion. On the other hand, it is merely palliative in neuritis due to intra-cranial tumour. The operation, under any circumstances, should be performed with care, and the amount of liquid evacuated should be in inverse proportion to the severity of the symptoms of compression. It is better to renew the puncture as often as necessary rather than to do too much at one time.

RECENT INVESTIGATIONS ON DYSENTERY.

By R. KRUSE, M.D.,
Professor of Medicine in the University of Bonn.

[Specially Reported for this Journal.]

As has always been shown, the dysentery that is met with in Germany is almost exclusively the bacillary form, not the amœbic. Of the former, two groups are to be distinguished, the true and pseudo-dysentery. The bacillus of the first group, generally known as the Shiga-Kruse bacillus, is found over almost the whole earth. I have selected the name pseudo-dysentery for a double reason—first, because the bacillus of it agrees in all essential particulars with that of the true bacillus, and can be only distinguished from it by the specific reaction in the blood serum of patients suffering from the disease, and that of immunised animals; and, secondly, because the diseases set up by it do not show such typical symptoms as true dysentery. It is owing to this that, since the time of Widerhofer, enteritis follicularis, which is nothing else than a pseudo-dysentery, has been distinguished from true dysentery. The less well-marked symptoms of dysentery seem to correspond to the fact that pseudo-dysentery affords a distinctly better prognosis. Its dissemination is very considerable. The disease has been met with in the most varied regions of Germany, in Austria, Holland, Constantinople, Ceylon and China. It does not appear in such great epidemics, but more in the form of small epidemics, and especially also in the sporadic form, but very frequently, and extended over a large area. The frequency of pseudo-dysentery in asylums for the insane is very striking; in these places it is quite endemic. They afford a good nutrient soil for the infection, and when it has once got in in any way it is very difficult to get it out again. Here it can often be proved to be an infectious disease, as it does not spare even the attendants and medical officers. Outside of institutions it is often very difficult to ascertain the source of the infection and the manner of its dissemination.

It has already been stated that the properties of the bacilli of dysentery, as well as those of the pseudo-dysentery, possibly permit of their remaining alive for months outside the patient's body. Practically it is nearer the mark to assume that there are bacillus carriers or go-betweens in dysentery and pseudo-dysentery; such have been met with in both forms of the disease.

Whether the suspicion expressed by Jehle and Charleton that pseudo-dysentery is communicated by food that has gone bad is correct as regards the majority of cases must remain undecided. An explanation of the origins of outbreaks of pseudo-dysentery is rendered very difficult by the fact that there are various forms of it; and, secondly, for the reason that a bacteriological determination of the disease is no small matter. Still, a number of different types of isolated bacilli have been distinguished. The agglutination test has proved the most certain. The following genera have been distinguished amongst the pseudo-dysenteric bacilli (Abarten or Typen).

1. Pseudo-dysentery A, or the first chief race.—The bacilli attack neither milk, nor malt, nor cane sugar to any great extent, and they are agglutinated by the serum of almost all the other kinds almost as strongly as the "homologous" stems, B H. Inversely the serum of this genus acts on bacilli B almost as much as its own bacilli, C usually the same, D and E frequently the same, but usually more feebly; the others but little or not at all. It seems to be the type most frequently met with in Germany.

2. Pseudo-dysentery B is distinguished from A only in that it decomposes milk sugar with the formation of an acid, and does not saturate agglutinine A (whilst A saturates that of B). As regards immune serum the behaviour of both is the same.

3. Pseudo-dysentery C embraces only two cultures. The one acidifies maltose, the other not; as regards serum, the behaviour of both is the same; they do not saturate any other serum.

4. Pseudo-dysentery D, or the second chief genus.—Of 15 stems, only two acidify malt sugar. They are more or less influenced in serum A, B, and C, only slightly in the rest. Serum D agglutinates A and B alike, the other genera only slightly. Mutual saturation does not take place with other kinds.

5. Pseudo-dysentery E.—Acidify malt and milk sugar and curdle milk in 8 to 14 days; can be very sharply agglutinated by serums A C, and inversely influence these stems in their own serums. Mutual saturation is not possible. Active immunity for A, D and E only applies to their respective genera.

6. Pseudo-dysentery G, H, etc., are terms applied to a number of genera that cannot be classed in the previous groups, and which mostly differ amongst themselves. Some attack milk sugar, others all three kinds of sugar.

Compared with the many-visaged image presented by the pseudo-dysenteries, that of true dysentery is very uniform and distinct. First of all, the manuit and indol tests are always negative. Then the true bacilli are agglutinated but little or not at all by the pseudo-serums. Active immunity only applies to the kinds affected. Sub-divisions of true dysentery could not be established, although attempts were made in that direction with stems from all parts of the world. The occurrence of different genera in true dysentery is, however, by no means impossible.

Doubt is no longer possible as to the causative significance of the bacilli of the two chief genera of pseudo-dysentery, for the reason that they are found so frequently, and always with the same characteristics. The behaviour as regards agglutination in the serum of dysentery cases, and, lastly, a case of laboratory infection recently observed (genus A), are in favour of this. The different divisions of each genus differ only little from each other, and have preserved their characteristics for years unchanged. Further, in the same person only strains of the same genus have been met with. Finally, the cases of dysentery of the same epidemic have in general belonged to the same type. Exceptions have, it is true, been met with, but they have been explained as infections from other sources, and not as variations of the same virus, that therefore the different genera must be considered as essentially constant—*i.e.*, in the somewhat limited sense, as with all other bacteria.

The diagnosis of the forms of dysentery is easy when the bacilli can be cultivated with the aid of Würtz's milk sugar, litmus agar, or gelatine painted plates, from the evacuations. The suspected colonies are dipped into sugar agar, mannite agar, milk or bouillon, and are best taken, not from the plates, but from the bouillon culture for the purpose of being tested with the immune serums for agglutination. Unfortunately, it is not always possible to get hold of the bacilli, and failures are not infrequent when the evacuations are not fresh or are not typical. When there is no result, by the help of the agglutination test in the disease serum, we can solve the question with great probability as to whether the case is one of true dysentery or not. The diagnosis of pseudo-dysentery and its varieties is more difficult, as, unfortunately, the blood serum of healthy people—and even that of new-born infants—frequently agglutinates these bacilli to a sufficient extent, whilst that of patients often fails.

With these difficulties of investigation it is not to be wondered at that the diagnosis remains doubtful in unfavourable circumstances, and that many investigators have drawn the conclusion that, besides the bacilli of dysentery and pseudo-dysentery, there are still other excitors of the disease. This notion may not be rejected summarily.

Moreover, every dysentery must not be looked on as an infectious disease; there are hæmorrhagic and dysenteric catarrhs of the large intestine of purely toxic origin. Mercurial poisoning is a well-known example. The possibility may also not be denied that from various injurious causes, such as a cold drink, the use of unripe fruit, a chill, etc., although these may not set up dysentery, yet the germs that inhabit these parts in greater or lesser numbers may become virulent, and dysentery be set up by self-infection. It is very probable that many intestinal diseases, especially in infants, are nothing more than such self-infections. When the effect is restricted to the large intestine, we have a condition of dysentery. The experiments of C. O. Jensen on new-born calves that have placed our knowledge on a firmer foundation have shown that self-infection and capability of transmission are not excluded. The bacteria once become virulent, set up the same disease in healthy calves. Even in the above-named intestinal diseases of infants, the capacity for infection is general. Possibly in these cases the bacilli are those of pseudo-dysentery.

The attempts to produce in animals a disease having the essential characteristics of human dysentery have, as in earlier times, been unsuccessful. On the other hand, we have learned to understand better the toxic effects of the bacilli of dysentery. After carefully testing the communications of Conradi, Vaillard, and Dopter, Neisser, Shiga, Rosenthal and others, we reach the following conclusions:—The bacilli of dysentery produce a poison which, introduced into rabbits even in small quantities, generally kills them with symptoms of a peculiar progressive paresis and convulsions. The simplest way of producing the poison solution is to wash the germs freshly grown on agar in a saline solution, keep them at a temperature of 60° C. for two hours, and then separate it from the bodies of the bacilli by centrifugation. Heating above 80° to 100° C. almost completely deprives the poison of its power. The intestinal changes have only rarely been seen in rabbits, and then only to a slight extent. The hæmorrhagic enteritis in dogs, on the other hand, is often limited, as in dysentery, to the lower part of the intestines, and not seldom developed in the duodenum and colon only. Experiments with other bacteria showed that in the dog all possible kinds of bacteria poison set up a hæmorrhagic enteritis, frequently similar to dysentery. The different kinds tested were the prodigiosus, the bacilli of typhus and paratyphus, the bacillus coli, and staphylococci. There is, therefore, no question of a specific dysentery poison, but of an effect common to all bacteria, a bacteria protein action.

From these experiments we can conclude, first, that the bacilli of dysentery have a specific and powerful action on rabbits, and that, besides this, they form at least one other poison that is less powerful and characteristic in the case of guinea-pigs and dogs. In applying these results to the human subject we must be very cautious. The symptoms of poisoning that are rarely absent in dysentery, as in other infectious diseases, are not by any means to be compared with those of rabbits, and may be explained by the effects of the guinea-pig poison. The possibility that the human subject may be susceptible as regards the rabbit poison cannot at first be denied.

The experiences gained with the dysentery poison are important in other respects also. There is, first, the result of the experiments with dogs, then the varying failure of those with rabbits; further, the extraordinary unequal susceptibility of the usual laboratory animals, for dysentery poison is perhaps due to the want of a suitable animal for experiment when we are so little fortunate in being able to procure the specific poisons of other infections—typhoid and cholera, for example.

Along with the intoxicant, the so-called "aggressive" actions of the excitors of infection have come more to the front, after remaining neglected to some extent during the fourteen or fifteen years that have elapsed since I first brought them forward. R. Pfeiffer and Friedberger associated the side chain theory with the aggressine (lysine) hypothesis. Bail believes that the aggressines manifested themselves in the locality into which they were brought—*i.e.*, in the living animal in which they developed The aggressines are supposed to be the substance through which the resistance of the body to growth is overcome. Bail believes, indeed, that he has found the specific aggressines in the most varied exudations. It is possible that may be so, for some cases—anthrax, for instance—but in others it has been shown that the matter is not so simple. The explanation of this probably lies in the fact that the aggressines become too readily combined at their place of origin, and that free aggressines, therefore, are no longer to be met with in the exudations. For the purpose of producing the aggressive action, it will be well, wherever possible, to make use of the bacteria cultures. The facts that have been brought to light in this respect have not yet been exhausted by experiment, so far. The culture aggressines that have been prepared out of the bacilli of dysentery are a proof of this. In the case of guinea-pigs the extract is so aggressive that the thousandth part of the usual minimum fatal dose develops, so that in the course of a few hours the peritoneum and blood are flooded. It is probable that anti-bacteriological and anti-opsonic effects come into play, as specific diphtheria serum has the power of neutralising aggressine. Naturally, one would desire that the aggressine should act specifically, and, in fact, it appears to do so, but to a certain extent only. Streptococci are apparently not affected at all; staphylococci and cholera bacilli somewhat; pseudo-dysentery and coli form strongly, but not so much as the bacilli of dysentery. The importance of mixed infection in the dysenteric intestine is known to every inquirer. As work is still in progress, nothing more need be said at present.

In regard to the further study of the more important questions of immunity, I was obliged to study anew the doctrines of infection, as by the peritoneum, the blood, the lungs, etc. I was able thus to confirm the statement of Werigo as to the astonishing power of consumption of the endothelial vessels, and especially those of the liver, on which the immunity of animals in blood infections plainly rests. The great importance of phagocytosis has also been made manifest. We must accustom ourselves to the thought that in infection a real struggle takes place, the outcome of which depends not only on the forces brought into action on both sides, but also on the new forces developed within.

All the forces that have been shown to exist in the juices are present in a united form in the serum of dysentery—bactericide, opsonic, and also antitoxic. The antitoxic—to mention this first—appears to act in a somewhat capricious manner. The serum I have used for the last five years has always been prepared in the same way from fresh dead agar cultivations at 60°; the procedure unites in itself all the advantages that can be expected theoretically, and the immunisation is more readily effected when the bacilli bodies are not removed. The importance of the pure antitoxic serums is over-estimated. We are not justified in calling upon diphtheria serum, the action of which cannot depend exclusively on neutralisation of the poison. We observe under its influence, however, a cessation of the diphtheria infection—*i.e.*, an aggressive action, not alone a removal of the symptoms. It is very probable that, whenever the antitoxic influence of the serum of diphtheria comes into play in the human subject, the bactericide and opsonic action which I have proved to exist participates in the effect produced. In any case, favourable results have almost always been obtained in the treatment of diphtheria by serum. Hitherto these results have not been improved upon by the employment of living dysenteric bacilli for purposes of immunisation, as asses and horses even highly immunised are very susceptible to the administration of living bacilli, an indication that we have in living bacteria still further toxic substances which we have not yet got hold of.

As regards successes in the use of the serum of pseudo-dysentery, no report can be made, as the animals used in the experiments have all died through repeated accidents. A limited influencing of pseudo-dysentery by the serum of true dysentery, and *vice versâ*, and of pseudo-dysentery of one kind by the serum of another kind, is, judging from test-tube experiments, within the range of possibility; especially the serums prepared from races A and B appear to react mutually on each other.

The London Fever Hospital.

Two new wards containing 27 beds were opened recently by Lady Balfour of Burleigh, who with Lord Balfour made a tour of inspection of the wards, accompanied by members of the staff. His Lordship said that although one of his medical friends had remarked that the present occasion would be the only opportunity for at least fifty years for the average member of the community to come into the building with complete safety, he himself believed that with all the modern devices for disinfection and sterilising germs, this hospital was a more healthy and safe place for people to live in than walking about the streets of London with the chance of being run over. The institution could look back on a useful career of more than one hundred years. Dr. Sidney Phillips, senior physician, having obtained permission from Lady Balfour to name the new ward the "Lady Balfour Burleigh Ward," the proceedings closed with a hearty vote of thanks to Lord and Lady Balfour.

THE annual dinner of the Royal Medical Society of Edinburgh was held in the hall of the Society in Edinburgh on February 5th, Dr. A. C. B. M'Murtrie, senior president, in the chair. The guest of the evening was Mr. Jonathan Hutchinson, F.R.C.S., LL.D.

ECTOPIC GESTATION. (a)

BY HENRY BRIGGS, M.B.ED., F.R.C.S., ENG.,
Professor Midwifery, Liverpool University, etc.

THIS paper on the diagnosis and treatment of ectopic gestation, mainly founded upon a clinical study of 124 cases of interrupted early gestation marked by physical signs and symptoms, at, or before, the end of the second month; deducted from an inclusive total of 139 cases, all of them treated by operation, the 124 cases left 15 others, nine at two to six months, two at six months, three about full term, and one nine years after the full term, not included in the paper. The earliest disturbances amongst the 124 early ectopic gestation sacs occurred after intervals of six, ten and eighteen days beyond the cessation of a previous normal and regular menstruation. For the group of clinical symptoms and signs, indicative of these disturbances, Dr. Briggs, fifteen years ago, had instituted and since adopted the term *peritoneal crisis*. The symptoms and signs of sudden onset were often moderate or mild, and that even trivial, locally recurrent pains, together with slight, irregular menstrual and intermenstrual blood-loss, were not to be construed as harmless or insignificant until the physical signs had been closely watched or waited for. A more prompt appreciation of their significance and of what may lie before the patient would lead to earlier and easier and safer operations, and to the more frequent recognition (with the Trendelenburg position for operation) of "unruptured tubes," and a little free intra-peritoneal blood, even in cases where the acute peritoneal crisis had been recent and severe.

To postpone operation is to incur adhesions and hæmatocele sacs in their various forms. The peritubal (Sänger and Taylor) and the para-tubal (Sampson Handley) hæmatocele sacs, for their intact removal, must be in a suitable physical condition; earlier and later in their course the physical conditions may defy intact removal. Intact removal is not indispensable, but the handling of organised and organising tissues, especially of adherent blood clots, or simply draining them, does not diminish the post-operative risks. Localised hæmatocele sacs as intra-peritoneal formations, subsequent to originally free intra-peritoneal hæmorrhages, possess a stage at which there is both free and localised blood; the free blood outside the hæmatocele sac in process of absorption may be accepted as evidence of secondary rupture of the tubal or hæmatocele sac.

The older statistics of the prevalence of tubal rupture are probably inaccurate in consequence of the frequency with which gestation sacs were torn or ruptured by the fingers of the operator. In the future the continued use of the Trendelenburg posture, lending sight and light to the lower abdomen, would show, as it had shown in his more recent experience, that gestation sacs before operation are rarely ruptured.

Werth and Taylor and Bland-Sutton have established their respective contributions to the process of tubal abortion. An examination of various old gestation sacs, nine years old downwards, demonstrates which may remain in a latent or active form in the patient after apparently successful expectant treatment. During the first ten years up to the end of 1897, one vaginal and 20 abdominal sections, compared with the second ten years 17 vaginal and 101 abdominal sections, denoted a change from expectant to operative methods in the author's practice. Nine of the cases show bilateral lesions, on one side a tubal gestation sac and on the other a pyosalpinx once, a small ovarian cyst twice, and old, adherent inflamed tubes six times, masking the diagnosis of ectopic gestation from the symptoms. A three years old and a recent tubal pregnancy on opposite sides co-existed in one case. A second tubal pregnancy on the opposite side had been treated by a second operation in three of his patients.

Dr. Briggs referred to a paper he himself read in 1897, in which he had produced evidence that intraperitoneal hæmorrhage and hæmatocele were occasionally associated with lesions other than those of ectopic pregnancy. The very rare rapid fatalities associated with tubal rupture form a very small class of their own; operative treatment, if at hand, is almost excluded by the brief space of time available. "To operate," says Dr. Champneys, "during the state of shock is, in many cases, to kill the patient." Dr. Briggs said he had invariably acted on this principle, and he showed a series of ectopic sacs successfully removed from patients after they had recovered partically or wholly from a peritoneal crisis. The severity of a peritoneal crisis was no certain measure of the amount of hæmorrhage. He was of opinion that, with this exception, delay in the operative treatment of ectopic gestation increased its dangers.

There were two deaths following operative treatment amongst his 124 cases, (*a*) after an unusually troublesome and risky operation amidst dense adhesions in a patient who had refused operation for appendage disease three months previously, and (*b*) after the operation for abdominal drainage of a very large hæmatocele in a very anæmic woman; death resulted from anæmia.

(a) Abstract of paper read before the Liverpool Medico-Chirurgical Society, January 30th, 1908.

THE SYMPTOMS AND ETIOLOGY OF MANIA. (a)

BY LEWIS BRUCE, M.D.Ed., F.R.C.P.Ed.,
Superintendent of Murthly Asylum.

THE lecturer first referred to the inadequacy of the psychological path of inquiry to elucidate the nature of mental disease; if our knowledge of the intricate mass of symptoms called insanity was ever to be advanced, it must be by attacking the problem from the physical side. The subject to be discussed in these lectures was the physical symptoms to be observed in the class of mental disease known as acute mania. Mania constitutes between 50 and 60 per cent. of all admissions to asylums, and is a disease of adolescence, or early adult life; the two main types are mania will confusion, and manic-depression, insanity in which depression alternates with exultation, but there is little or no confusion. Confusional mania is liable to become chronic, and pass into delusional insanity and ultimately dementia. Dr. Bruce went on to say that the causes of all insanities, particularly mania, were physical. The emotional crises, so often regarded as causal, were symptoms of an unstable brain, just as alcoholism was more often a symptom than a cause. The most generally predisposing cause was heredity, which included not only mental disease in the parents, but alcoholism, tubercle, hysteria, criminality, etc., or any weaknesses in the body defences against toxic and bacterial invasion. As to the exciting causes, Dr. Bruce believed they were toxins of bacterial nature, and that the bacteria was allied to the *micrococcus rheumaticus*. Though he had not found a specific organism in every case, there was always evidence of a specific bacterial invasion. Second, he had produced evidences of lesions in the nervous system of rabbits, showing that the bacterial toxins attack nerve tissues. Third, in using vaccines made from organisms isolated from cases of mania, a marked exacerbation of the symptoms occurred if the doses were too large. Fourth, the blood serum of infected rabbits shows the same changes as those in man; and fifth, a pure culture of the organism has been obtained from infected rabbits. In working at the opsonic indices of insane persons, it has been found that their serums often agglutinated the normal red corpuscles, but did not agglutinate the corpuscles of other cases of mania; this was observed in over 90 per cent. of the cases of mania investigated. Further work on persons who were sane, and either otherwise healthy, or suffering from known bacterial invasions, showed that about 50 per cent. of normal persons, and a large number of bacterially infected, gave the reaction—that is, did not agglutinate in the presence of serum of mania, in other words, were immune to the agglutinating substance. He had been able to produce a similar reaction experimentally, by inoculating rabbits with various organisms, isolated from cases of mania, and with Ford-Robertson's *B. paralyticans*. The serum of the infected animals agglutinated a control rabbit's corpuscles, but not the corpuscles of other infected animals. From this it is inferred that when a patient's serum agglutinates the corpuscles of a healthy person, the person from whom the serum is derived is probably suffering from a coccal infection. But as the sane and insane both show evidence of bacterial toxæmias, there must be differences in the two. The brain of the insane is hereditarily unstable, and there is probably also a constitutional weakness of the bodily defences. In mania, the leucocyte counts show a marked abnormality. Even though the temperature remains normal, there is constantly a very definite polymorphous leucocytosis. Among other physical symptoms, are disorders of the alimentary tract, particularly septic conditions of the mouth, the saliva of which teems with bacteria. The digestive and bactericidal power of the gastric juices are also poor. One of the most remarkable changes, however, is the alteration in the flora of the fæces. Culture from the fæces of acutely maniacal patients very often do not show the great numbers of b. coli found in health, but instead yield streptococci. Sometimes the streptococci alone are present, b. coli being absent. The pulse is rapid, and the blood pressure low, except at the onset of acute excitement. The metabolism of mania resembles that of a febrile condition: during the acute stage the urinary nitrogen exceeds that of the food, then there is a period of balance, and afterwards, during convalescence a stage of nitrogen retention and gain in weight to make up for the early loss. All these signs—the agglutinating property of the blood, the leucocytosis, the disorders of digestion, the organisms in the fæces, or the nitrogenous output, go to show that mania is due to an infectious process.

(a) Abstract of Morison Lectures on Insanity, delivered in the Royal College of Physicians, Edinburgh, on January 27th, 29th and 31st, 1908.

The normal blood serum agglutinates staphylococci, and may also contain other agglutinins the result of disease—*e.g.*, typhoid, etc. Specific agglutinins may be found indicating that a patient is suffering from a particular microbic invasion. In persons suffering from mania, Dr. Bruce had been able to detect agglutinating substances in many streptococci: these are rarely present in health, or in other forms of mental disease. In all, some five strains of streptococci have been isolated from patients suffering from mania, and these are agglutinated by the serums of nearly every case of mania; using as controls the *personnel* of the asylum, and non-maniacal patients, only 15 per cent. agglutinate these streptococci. Conversely, the normal agglutinating power against staphylococcus aureus, is very much less frequent in mania than in health. Dr. Bruce then shortly recapitulated his already published observations on the leucocytes in acute mania, the leading feature being the very marked hyper-leucocytosis of polymorphs, which is found in the blood during the acute stage, irrespective in many cases of any coincident rise in temperature.

Turning again to his investigations as to the causal organism of mania, the lecturer described in some detail his methods of isolating it from the intestines and urine. In a large proportion of urines of cases of mania, collected with antiseptic precautions, various strains of streptococci were found. In health, the same organism was met with, though less commonly. The method of examining the fæces was to make stroke cultures on six successive agar tubes. Normally, the growth of b. coli is so luxuriant, as to crowd out all other organisms, but in cases of mania streptococci are very common. Slides were shown, illustrating an almost pure culture of the latter, with very few colonies of b. coli. This peculiarity was met with in 15 out of 27 cases examined. The presence of streptococci in the urine was probably due to their entering the blood stream or lymphatics from the alimentary tract (which showed gross pathological changes in almost all cases examined post mortem), and ultimately being excreted by the kidneys. Attempts were made to produce an antiserum to these organisms by injecting them into goats, but without success. The study of the opsonic index in mania to these strains of streptococci showed several points of interest. For the controls, pooled sera were used, and the normal index was taken as between .8 and 1.2. In mania the opsonic index showed variations very much wider than any obtained in healthy persons. Vaccines of these organisms were prepared, and produced a negative phase, followed by a positive phase in the usual way. During the negative phase, or when the opsonic index was low, the patients suffered from excitement; during the positive phase, or high index, the symptoms abated. It is well known to all asylum attendants that patients with mania had good days and bad days, and that their symptoms tended to remit. Repeated observations on the opsonic index showed that the index was low when the symptoms were acute, high during the remissions. To illustrate the similarity to the micrococcus rheumaticus, charts were shown giving analogous results on the injection of vaccines of that organism into persons suffering from rheumatism. It was impossible by means of vaccines to maintain the opsonic index at a high level for any length of time. Dr. Bruce's theory of the cause of mania is, that it is a bacterial poison formed in the intestinal tract. Owing to the lowering of the bacterial defences of the body, certain organisms flourish unduly in the intestines, where they elaborate toxins which are all absorbed into the blood. These poisons have an affinity for the nerve elements, and when absorbed in sufficient quantity, they produce brain intoxication and an attack of mania. The defences of the body are stimulated to action by the presence of these poisons, and antitoxins are formed, which temporarily neutralise the toxins, and apparent recovery ensues. The infecting organisms, however, being in the intestines, are not affected by the protective substances, so that any lowering of the general health may be and frequently is followed by another poisoning of the brain, and further attacks of mania.

A NOTE ON THE

VOMITING OF ANÆSTHESIA. (a)

By L. G. GUNN, M.D.,

Assistant Surgeon to the Adelaide Hospital, Dublin,

THE medical man who makes anæsthetics his special study, knows, as a rule, comparatively little about the vomiting which so frequently follows their administration.

The patient may be sick once, or perhaps twice, before he leaves the anæsthetist's hands, but he is still unconscious, and does not complain. The surgeon who has to see the patient later on during the day realises more fully the misery caused by this post-operative vomiting, the nurse who sits for hours beside the patient's bed could probably write an astonishingly strong article on the subject, while, if the patient were asked to place his ideas on post-anæsthetc vomiting on paper, I fear in most cases the communication would not be fit for publication.

There is no need for me to attempt to prove that, quite apart from the misery entailed on the patient, vomiting after an operation is often a real danger to the success of the operation, not only in general surgery but also in many of its special branches; that such is the case is generally accepted by the medical profession. Why then is so little done to stop this post-anæsthetic vomiting? Because I think it has come to be looked upon as a necessary evil. Our forefathers looked for and expected laudable pus as the natural sequela of any operation, and were seldom disappointed. We know better now, but are we not inclined to take up to-day somewhat the same position in regard to the vomiting which follows the administration of a general anæsthetic?

There are three unpleasant sequelæ to anæsthesia, headache, pain in the back, and vomiting. I only wish to deal with the last and greatest of these this evening, but would remark in passing that the loin pain is probably due to a direct irritation of the kidneys, a fair proportion of cases, whose urine was normal before the administration of the anæsthetic, show traces of albumin and hyaline tube casts in the urine for several days afterwards. I have found such a condition present in about 20 per cent. of the cases I have so tested, but I have done little work on this particular subject, and observers with large experience put the percentage much higher than this.

At the Adelaide Hospital year by year we average well over 600 anæsthetics, and for several years I now have had the benefit of this material at my disposal for observation on post-anæsthetic vomiting. I am not going to give you any figures, but merely the conclusions I have formed on this subject, nor are these conclusions in any sense my own; probably all have been advanced time and again before now. I believe, however, that they are correct.

1. The careful preparation of a patient before an anæsthetic is of some importance, but not of very great moment. Preparation can easily be overdone, *i.e.*, a patient starved too long a time before the anæsthetic is likely to have more vomiting than one who had received no preparation at all.

2. The vomiting is in no way dependent on the anæsthetic administered. I have only experience of three varieties, chloroform alone, chloroform followed by ether, and gas followed by ether; sickness follows each of these three forms equally.

3. The vomiting does not depend on the amount or duration of the anæsthetic. A short anæsthetic may be followed by as severe vomiting as one that may have lasted for a couple of hours.

4. The part of the body operated on does make a considerable difference. Abdominal operations, and especially those on the generative organs, are specially liable to be followed by severe vomiting. For this reason the gynæcologists see probably more troublesome post-operative vomiting than any other class of operator.

5. Sex is not a factor. Men suffer equally with women, but children, as a rule, suffer less; they probably have a smaller proportion of abdominal operations performed, and almost never have severe operations on their generative organs.

From time to time drugs in some shape or form have been recommended for the prevention of post-operative vomiting. I have tried many; none have been to any degree successful. To enumerate these methods would be useless.

Some months ago Dr. Bewley drew my attention to an article by Dr. MacArthur, of Winnipeg, in the *Montreal Medical Journal* of June, 1907. He gives the following explanation of the vomiting which we are considering to-night:—"The patient receives little or nothing in the way of food for twelve hours before the anæsthetic is administered; consequently, the stomach is empty. During the administration the saliva becomes surcharged with the anæsthetic, and trickles down the gullet into the stomach, where, in its concentrated form, it attacks the mucous membrane and causes gastritis; the vomiting naturally follows on this inflammation. When the stomach is full of water, the anæsthetised mucus swallowed mixes with it, and is absorbed in such a diluted form that it does not irritate the mucous membrane of the stomach." Acting on this assumption, MacArthur prepares his patients in the following way. After midnight, on the day of the operation, the patient is given four ounces of fresh cold water to drink; this is repeated every fourth hour, until two hours before the operation, when about ten ounces of water is given, and this is repeated just half-an-hour before the anæsthetic begins. In this way you fill up the tissues that have been depleted by purging, as well as put the stomach to its full capacity. Out of 35 cases treated by MacArthur in this way, only four had any trouble from post-operative vomiting.

This method appealed to me, as being harmless, simple to carry out, and likely to make the patient more comfortable before, if not after, the operation. With Dr. MacArthur's reasoning I cannot entirely agree. I cannot think that once the patient is fully under the anæsthetic that any saliva is swallowed; also he is wrong in thinking that at the time of operation the stomach remains full of water, for I tried palpating the stomach in several cases of operation on the upper part of the abdomen performed on patients who had been given this water treatment. In each case the stomach was nearly empty, so that now I have modified this method to this extent—that the last drink of ten ounces of water is given just as the patient leaves for the anæsthetic room.

I have tried this plan now on about 40 cases; in nine of these there has been no vomiting whatever after the anæsthetic, in 12 of these cases vomiting came on in the usual way, and I could not satisfy myself that the administration of the water had in these cases really made any difference. The remaining 19 were all improved, some being only sick once, and that very slightly. Several of these patients had had an anæsthetic before, and all remarked that it had been much less unpleasant on this occasion than the first time.

When this water treatment succeeds, there is marked absence of headache, thirst, and retching. The odour of the anæsthetic is quickly eliminated from the system, and the patient is able to take and enjoy nourishment in from six to eight hours after the operation. I do not for a moment suppose that this method is either new or that it has solved the problem of post-anæsthetic vomiting, but I do think that it is sufficiently simple and successful to be worth a trial. What I feel most strongly is, that it is an effort in the right direction, and along correct lines, which may in time lead us to a method of giving anæsthetics in which there is no risk of vomiting following.

(a) **Paper read before the Surgical Section of the Royal Academy of Medicine in Ireland.**

I have avoided the question of spinal and local anæsthesia. Their disadvantages seem to me to be greater in many cases than their advantages, and certainly they are by no means free from danger. The surgeon is responsible for the preparation of the patient for his anæsthetic; surely the treatment and prevention of post-anæsthetic vomiting lie more in our domain than in that of the anæsthetist.

The possibilities in these aseptic days, which are opened up for rapid healing, freedom from pain, and delicacy of technique, could we but be certain that no straining would follow the anæsthetic, calls for great effort on our part to attain to this end. I would be ungrateful indeed did I not in closing express my indebtedness to the anæsthetists for the high state of excellence to which they have brought their art.

It is no small comfort to the surgeon to know that in the hands of the Dublin anæsthetists the risks to a patient of a general anæsthetic become almost inffinitesimal.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

FRACTURED PATELLA.—MR. WILLMOTT EVANS operated on a woman, æt. 39, who had been admitted suffering from injury to the left knee. She had slipped down seven steps, and her left knee went under her; she was picked up, but was unable to stand. She was taken home, and remained in bed five days; with some difficulty she got about for the following days, and then came to the hospital. On admission there was much swelling and bruising round the left knee, extending upwards to the junction of the middle and lower thirds of the thigh. On palpation a fractured patella was found, the fracture being horizontal, the upper fragment forming only a fourth of the whole bone; the fragments were separated more than one inch. The leg was put on a back splint, and lead lotion applied to the affected area. Four days later the operation was performed. The patient having been anæsthetised a horse-shoe shaped incision was made from a little above the inner condyle passing downwards to immediately above the tubercle of the tibia, and then upwards to a corresponding point on the outer side. A flap composed of skin and subcutaneous tissue was turned upwards, and the fragments of the patella exposed; it was seen that the capsule of the joint was torn on both sides of the patella in a line with the fracture. A large quantity of clotted blood filled the joint cavity; this was removed, special care being taken to cleanse the fractured surfaces; the torn periosteum projecting from the edges of the patella was cut off. By means of an awl two holes were drilled in each fragment, commencing on the anterior surface and ending on the fractured surface. A piece of silver wire was passed through the inner and outer holes, and the two fragments drawn together. The wires were twisted twice, the excess cut off, and the ends hammered into the bone. The joint was then irrigated with normal saline solution at a temperature of about 103°. The torn capsule was united by silk sutures, both at the inner and outer sides of the patella. The skin edges were brought together by interrupted sutures, and the wound dressed. Mr. Evans remarked that at the present day the best treatment for an average case of transverse fracture of the patella was suturing. In the first place it might be mentioned that, although a majority of cases of transverse fracture of the patella were due to muscular action, yet in a not small proportion direct violence may cause a transverse fracture. Not only is this shown by the history, but often, as in this case, a large amount of local bruising makes it almost certain that direct violence had been responsible for the fracture. The injury to the soft tissues makes them a little more susceptible to septic influences, and therefore, in suturing such cases of fracture, the surgeon has to be extra cautious not to permit the introduction of micro-organisms. The best incision for this operation, he considered, was the horse-shoe, but the convexity of it may be either upwards or downwards to suit the operator's fancy. One great merit of this open operation, he thought, was that the blood effused into the joint can be removed, and this is not possible if any subcutaneous method of wiring was adopted. Bony union was also furthered by removing the fibrous tags of the torn periosteum which interpose themselves between the two fragments, but unless extreme care be employed, the risks of suppuration of the joint are by no means small. As to the method of union of the fragments, wire, he said, was usually employed, and does extremely well, and even fairly fine wire was quite sufficient to keep the fragments in apposition. Several surgeons, however, have used silk or catgut with good effect, for it must not be forgotten that, after the first few hours the force tending to separate the fragments was very small, and therefore somewhat slight sutures were quite sufficient. He regarded as desirable that the sutures, whatever their nature, should not encroach on the articular surface of the patella, as, should they do so, they must interfere, if only to a slight extent, with the movements of the joint. It was desirable, he pointed out, but not essential, to suture the torn capsule. No drainage was required if the surgeon was satisfied that the most strict precautions had been taken as to asepsis of the operation. A question arose as to when these operations should be performed—immediately or after a certain interval? His opinion was that in those cases in which the fracture was due to muscular action, no time was better than the second or third day after the injury, and no reason existed for further delay. The case, however, was somewhat different when direct violence had caused the breaking of the bone, for the tissues around the joint, and the skin over it, would certainly be damaged, bruised and œdematous, and therefore less suited for aseptic operations. In such cases as these a delay of a week or ten days was, in his opinion, useful, as it would enable the tissues to recover their normal condition, and therefore to be in a better state for operation. A splint for the first week after operation was, he thought, convenient, but by no means essential.

The further progress of the case was eminently satisfactory. The wound healed by first intention, the stitches were removed on the ninth day, and the patient left the hospital on the twenty-second day, walking well, with free movement of the joint. During the last week of her stay in hospital passive movement was employed.

A SERIOUS outbreak of typhoid fever has occurred at Workington. Since the beginning of the year 77 cases have been notified, and of these 52 have been reported during the present month. The Town Council are taking every practicable measure for dealing with the epidemic.

TRANSACTIONS OF SOCIETIES.

THE ROYAL SOCIETY OF MEDICINE.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION.

MEETING HELD TUESDAY, JANUARY 28TH, 1908.

The President, Dr. T. E. BURTON BROWN, C.I.E., in the Chair.

THE minutes of the previous meeting were read and confirmed.

The following gentlemen were elected to the membership of the Section:—John McDonald Brown, M.D., F.R.C.S.; Frederick William Higgs, M.B., B.S., M.R.C.P.

Professor W. E. DIXON announced that he had given evidence before the Royal Commission on Vivisection, as the representative of the Section.

Dr. BURTON BROWN proposed a vote of thanks to Professor Dixon for having done so. Dr. GRAY DUNCANSON seconded, and this was carried unanimously.

Professor CUSHNY gave an address on "Nutmeg Poisoning." He referred to the scanty recognition of this in English medical literature, and noted the work of his former assistant, Dr. Wallace, in America, who found that cases of poisoning occurred exclusively from the use of the crude nutmeg or mace. In many instances it had been used as an abortifacient, although it does not appear to have this action. As far back as 1576, Lobelius relates a case in which a woman was rendered delirious by nutmeg. The symptoms are drowsiness, stupor, diplopia, delirium frequently is present, and sometimes the first symptom is burning pain in the stomach, præcordial anxiety or giddiness. One case of death in a boy occurred after eating two nutmegs. The symptoms resemble those of cannabis indica. Professor Cushny showed how the powerful poison was contained in the oil of nutmeg, and it was the fraction which came over at 150° C., 14 mm. Hg. From this several bodies have been isolated—*e.g.*, myristicin. From experimental work Professor Cushny came to the conclusion that the symptoms are to be attributed to action on the central nervous system, which is depressed, but exhibits some indications of stimulation in the form of restlessness, slight convulsive movements and tremor. The oil also has a marked local irritant action, whether given by the mouth or hypodermically. The stomach wall is found red and injected; the urine often contains albumin.

Dr. POWER (introduced by Professor Cushny) said that he had been working on the chemistry of oil of nutmeg, which he found a very complex mixture. He had isolated large quantities of myristicin, which did not conform in its features with the substance described by Semmler under that name. He drew attention to the very small amount of myristicin contained in the quantity of nutmeg necessary to induce poisoning, this suggesting a doubt to his mind whether the symptoms were entirely due to this body.

Dr. J. GRAY DUNCANSON mentioned the case of a woman who aborted, after taking, amongst other things, a ground nutmeg in gin; she displayed the symptoms described.

Professor CUSHNY replied.

The PRESIDENT moved a vote of thanks to Professor Cushny for his valuable and instructive paper. This was seconded by Professor DIXON, and carried.

Professor W. E. DIXON dealt with arterio-sclerosis and its causation. He referred to two theories of causation—(*a*) raising of blood pressure; (*b*) toxic influences; and showed that it had been established conclusively by experiment that arterio-sclerosis could be produced in the lower animals by simply compressing the abdominal aorta for one minute once or twice a day for a comparatively short period. The changes consisted in a drawing out of the elastic fibres and degeneration of the muscular coat, plaques of calcareous material being formed. He explained how this might be brought about in man owing to violent exercise, and more especially was this likely to occur as man grew older, as the rise of blood pressure was then greater after exertion than in youth. Dr. Dixon also spoke of the effect of nicotine on the blood pressure, comparing the sudden high rise in the young nonsmoker, after his first cigar, with the slight rise in the moderate smoker, and the absence of effect in the habitual smoker. He concluded by stating that man produced a ferment, probably in his liver, which counteracted the effect of nicotine.

Professor CUSHNY hoped that the study of this subject might lead to some advance in treatment. He did not think that the raising of blood pressure in man, by the administration, for example, of digitalis, would give rise to these changes.

Dr. SAVILLE stated that he was surprised to hear that the compression of the abdominal aorta for such short periods in small animals should give rise to so serious changes in the aortic arch, as had been described by Professor Dixon.

Mr. MABEN spoke also.

The PRESIDENT proposed, and Dr. GRAY DUNCANSON seconded, a vote of thanks to Professor Dixon for the account he had given of the results of the valuable work he had done on this difficult and important subject.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FEBRUARY 5TH, 1908.

The Vice-President, Dr. HUNTER, in the Chair.

MR. F. M. CAIRD showed (1) patient after removal of a sub-maxillary gland, and (2) patient after removal of half the tongue and the floor of the mouth for epithelioma.

Mr. A. A. SCOT SKIRVING showed a large pedunculated fibroid, uterus, and adnexa removed by abdominal hysterectomy from a patient, æt. 70, in which a complete twist of the uterus had occurred, causing strangulation of the uterus, and symptoms of acute intestinal obstruction.

Dr. DAWSON TURNER read a paper on

ELECTROLYSIS IN MEDICINE AND SURGERY.

After referring to the earlier methods, he turned to the present day applications of electrolysis, in particular to the process of cataphoresis, or introducing medicines through the skin by means of the galvanic current. Solutions which conducted electric currents were known as electrolytes, and only such solutions could be introduced percutaneously. The electrolytic properties of a solution depended on the fact that the molecules dissolved in it—*e.g.*, sodium chloride—did not exist as sodium chloride, but were dissociated into ions—an Na-ion and the Cl-ion. The metallic ion was known as the kation and the chlorine ion as the anion—the former was positively charged with electricity, the latter negatively. The positive ions of an electrolyte are conveyed through the skin by the positive electrode, the negative ions by the negative electrode. This has been shown experimentally in the following way. If two rabbits be placed side by side so that a constant current can be passed through their bodies, the right-hand rabbit being in contact with the positive pole-anode, and the left-hand rabbit in contact with the negative pole-cathode, and if the two electrodes be kept wet with a solution of strychnine hydrochloride, the rabbit attached to the anode will be poisoned, and the other will escape. The anode drives in the strychnine kations, while at the cathode the hydrochlorine anions accumulate. When, however, we replace the strychnine by a solution of potassium cyanide, the rabbit attached to the negative pole-cathode is killed, as the poisonous cyanogen ion enters its body, and the inert-potassium ion that of the other rabbit at the positive pole. This method of administering drugs had, of course, many advantages; when it was desired to produce a total effect, *e.g.*, on a stiff rheumatic joint, we could introduce the remedy directly, without having to impregnate the whole body in order that the one part should benefit. On the other hand, only those drugs which are electrolytes can be made use of, so that cataphoresis is limited in this direction. Cataphoresis may be employed in a variety of affections. Dr. Turner had tried introducing the salicylic ion in cases of rheumatism, but his results had not been so satisfactory as those of several other observers. In rodent ulcer it was very serviceable. A solution of zinc chloride was used, several layers of lint being soaked in it and laid upon the ulcer, and the cathode applied over it. A current of from 10 to 40 m.a. was required. After two sittings, in some cases, the ulcer was markedly benefited. A number of other cases were referred to, and photographs were shown to illustrate the improvement brought about by cataphoresis. The chlorine ion had proved serviceable in various conditions of sclerosis and ankylosis, *e.g.*, Dupuytren's contraction. Tic doloureux was also very amenable to cataphoresis. It was suggested that some part of the benefit of the constant current in a number of chronic nervous affections was probably due to the action of the chlorine ion on fibrous tissue.

The paper was discussed by Dr. **Webster**, the **President**, and Mr. **Wallace**, who referred to cupric electrolysis in the treatment of ozæna. Dr. **Turner** said that the best method of applying cupric electrolysis would be, instead of using a copper electrode introduced below the nasal mucous membrane, to fill the nasal cavity with a copper solution and pass in the copper ions, using a copper cathode.

Dr. A. E. **Morison** read a paper on

ONE HUNDRED CONSECUTIVE CASES OF EMPYEMA.

He first drew attention to some points concerning the physics of pleural effusions. The intra-pleural pressure is positive in pleural effusion; in normal conditions the pressure is negative. Effusion into the pleural cavity first shows itself as an area of dulness—(*a*) just below the angle of the scapula; (*b*) in the left axilla, between the fifth and eighth ribs; (*c*) in obliteration of Traube's semilunar tympanitic space; (*d*) in the right front near the angle made by the cardiac and hepatic dulness. Disappearing effusion is last manifest in the axillary line between the fifth and eighth ribs. The root of the lung is its fixed point, and with increasing effusion the lung becomes compressed round it. The re-expanding lung last touches the chest-wall at a point diagonally furthest from its fixed point—*i.e.*, in the axilla about the fifth interspace. The lung does not tend to collapse on its fixed point when air is admitted into the pleural cavity. Turning to the causes of empyema in his series of cases, in the enormous majority the empyema followed pleuro-pneumonia, there being evidence of this in 91 per cent. Pleurisy was a cause in 4; this confirmed the experience of others that serous effusions rarely turned purulent unless they were infected accidentally. Tubercle was the cause of 3 cases; septic disease of the abdomen of 1; and general streptococcic infection of 1. The diagnosis of empyema rested partly on the history and partly on the physical signs. The patient had a pneumonia, and after the crisis there was not the usually expected improvement; the chest did not clear up properly, there was a febrile temperature, loss of flesh, night sweats, vomiting, fitful appetite, and cough. On examination of the chest one side would be found to expand badly; the ribs were usually approximated except in cases in which the effusion developed very rapidly; on percussion there was dulness over the affected region, with diminished vocal fremitus and resonance. The breath sounds were usually absent; in some cases (especially children) bronchial breathing was heard. The position of the heart was altered in effusions of any size, particularly those which were left-sided. On exploring with the needle pus was found. Dr. Morison urged the need for repeated puncture, if necessary, and said he had never seen any bad results whatever from this. The prognosis in uncomplicated empyema was good, the mortality in this series of cases being only 3 per cent. Absorption of pus undoubtedly occurred in some cases; this had been observed in one of the patients comprised in the series. In two cases cure followed spontaneous evacuation of the pus through a bronchus. Discharge of pus into organs adjacent to the pleura was another possible mode of termination, but no such condition had come under the speaker's notice. Empyema necessitatis, or spontaneous evacuation through the chest wall, occurred in 5 cases, subsequent operation being required. Surgical treatment offered the best results, immediate and remote. In ordinary acute empyema cured by drainage, there was complete return to health, and if the chest were examined a month or two after operation, it was impossible to say, except from the scar, which side had been affected. Although now and again aspiration was curative, it was only really advisable as a temporary expedient, as when dyspnœa is great, or some complication renders operative interference inadvisable. In adult patients the chest could often be drained under local anæsthesia; in children a general anæsthetic was required. The patient ought never to be turned over on the unaffected side; this could easily be avoided by drawing the patient well to one side of the table. It was always advisable to explore the chest so as to make sure of the situation of the pus immediately before operating. The site of election was in the fifth interspace in the posterior axillary line. In ordinary cases it was not essential to remove a rib. Simple incision with the insertion of a stout-walled drainage tube was enough. The pleural cavity ought not to be irrigated. As a rule the tube could be removed in about three weeks' time. Estlander's operation had been required in several of the cases. Dr. Morison illustrated his remarks by quoting the details of several of the more instructive cases in his series.

Dr. **Affleck** said that sometimes the odour of the pus showed its origin, and quoted a case of fœtid empyema arising from an appendicular abscess as an instance of this.

Dr. **Russell** was glad to hear that simple incision was sufficient treatment for so many cases. Formerly this had been the practice, but now surgeons always resected a portion of rib. He also spoke of the aid which was derived from the leucocyte count in the diagnosis of pus in the chest, and of the difficulty which exists in diagnosing deeply-seated diaphragmatic foci of suppuration. These latter were liable to terminate by evacuation into a bronchus. He doubted whether bronchial breathing ever occurred over effusion; it probably only was audible over the compressed lung near an effusion.

Mr. **Caird** agreed that incision was sometimes adequate, but thought that the advantage of resection was in enabling the surgeon to remove tough masses of lymph, and to ascertain the degree to which the lung was compressed. For resection a general anæsthetic was required.

Dr. **Goodall** referred to Professor Macewen's observations on the factors determining the absence of collapse of the lung when the chest wall was incised.

Dr. **James** said that in acute uncomplicated empyema incision was sufficient; in other cases it was better to resect. The reason why the pressure was positive in empyema was that the lung was bound down by adhesions and the pus gathered behind these.

Dr. **Morison** replied.

LIVERPOOL MEDICAL INSTITUTION.

Seventh Meeting of the Session, held Jan. 16th, 1908.

The President, Mr. **Thomas Bickerton**, in the Chair.

Dr. T. **Bradshaw** read a paper on "The Physics of the Mitral Regurgitant Murmur. Especially with Regard to its Audibility at the Heart's Apex." He assumed the correctness of the views held by George Balfour, Chaveau, Marey and others, that murmurs are due to the vibrations of the fluid veins formed in the space beyond the narrowing. The difficulty in explaining the mitral regurgitant murmur on this theory was that it was heard at a point (the apex) in the opposite direction to the fluid vein, which was directed towards the auricle. No explanation quite satisfactory had ever been offered. The writer's explanation was that the sonorous fluid vein lay between the two curtains of the mitral valve, and that its vibrations, transmitted to the cone of blood, passed through the thin walls without damping, and set up vibrations in the ventricle. The vibrations were heard best at the apex, because the walls of the ventricles were thinned at this spot, and this spot was most accessible to auscultation. He showed an apparatus constructed to show that sonorous vibrations could under similar conditions be conducted in a retrograde manner.

The paper was discussed by the President, Sir James Barr, Prof. Wilberforce, Drs. Lloyd Roberts and Buchanan, and Dr. Bradshaw replied.

EIGHTH MEETING OF THE SESSION, HELD JAN. 30TH, 1908.

The President, Mr. THOMAS BICKERTON, in the Chair.

Mr. ROBERT JONES described his operation for the production of pseudo-arthrosis at the hip-joint without disarticulation of the femoral head. The great trochanter was first separated from the shaft by a broad osteotome, and the neck of the femur either divided or removed, and the trochanter was screwed on to the head of the femur, which lay in the acetabulum. The operation might be employed in all varieties of bony ankylosis, but was eminently suited for old people with malum coxæ senilis where the shock of disarticulation was serious.

Mr. ROBERT JONES also described his procedure in the treatment of Volkmann's ischæmic paralysis, and his operation in paralytic calcaneo cavus.

The communication was discussed by the President, Messrs. Thomas and Newbolt and Dr. Abram, and Mr. Jones replied.

Dr. BRIGGS read a paper on

ECTOPIC GESTATION,

an abstract of which will be found on page 178 of the present issue.

The paper was discussed by the President, Drs. Grimsdale and Gemmel, and Dr. Briggs replied.

ULSTER MEDICAL SOCIETY.

MEETING HELD THURSDAY, FEBRUARY 6TH, 1908.

The President, Dr. JOHN MCCAW, in the Chair.

DR. W. B. MCQUITTY showed a case of juvenile general paralysis of the insane. The patient was a boy of 11.

Captain ARCHER, R.A.M.C., showed a patient suffering from paralysis of one arm, the result of a fall on the elbow. The diagnosis lay between an injury to the brachial plexus and a hæmorrhage into the cord, the general opinion being in favour of the former.

Mr. ANDREW FULLERTON showed a case of halux rigidus.

Mr. ROBERT CAMPBELL showed a case of longitudinal fracture of the styloid process of the radius (Chauffeur's fracture).

Dr. HICKS read a paper on "Some Cases of Extra-Uterine Fœtation." The paper was based on six cases in which Dr. Hicks had operated. All were in the early months of gestation. One was an example of repeated tubal gestation, the others were single ectopic gestations. In five of the six cases, or 83 per cent., there was a history of gonorrhœa previously. Two had pyosalpinx on the opposite side. One was complicated by an ovarian cyst and pyosalpinx on one side, and a ruptured tubal gestation into the pouch of Douglas on the other. Five of the six cases recovered. The connection between gonorrhœa and cases of this sort was first suggested by Lawson Tait, but he thought that the ciliated epithelium was injured by gonorrhœal catarrh. It is now known that the cilia are not destroyed, and that, moreover, their action is downwards from the tube to the cervix. American and German authors still look on gonorrhœa as the chief cause of extra-uterine fœtations, probably by producing interstitial changes in the wall of the tube, or peritoneal adhesions causing constrictions. Bland-Sutton and other English authorities teach that fœtation may take place in the healthy tube, but so far as Dr. Hicks' cases went, they certainly supported the other view.

CORRESPONDENCE

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Feb. 9th, 1908.

CUTANEOUS EPITHELIOMA.

THE treatment of epithelioma of the skin is either surgical or medical. The thermo-cautery or the X-rays represent the former, while the chemical or potential cautery forms the medical treatment. The surgical treatment has given good results, but is ordinarily not within the reach of the country practitioner. On the other hand, many pusillanimous patients refuse the actual cautery, consequently some more anodyne treatment must be employed.

Numerous were the agents proposed for cauterising superficial cancer of the skin. Bulroth used to say that he did not know of any agent that had not been employed for this purpose—nitrate of silver, proof spirit, tincture of iodine, acetic acid, arsenic, phosphorus, turpentine, etc. One of the most ancient drugs was arsenic, but in inexperienced hands the treatment produced disastrous effects.

It remained for Cerny and Truneck, of Prague, to rehabilitate this caustic by giving a formula free from all danger and radical in its cure.

They employed arsenious acid, which they used at first dissolved in glycerine, but had to renounce the preparation, as it produced such a thick crust or eschar that a second application was impossible. They changed, consequently, their formula for the following, which has been used with so much success by dermatologists:—

Arsenious acid, 15 gr.
Ethylic spirit, }
Water, } āā ℥ijss.

The seat of the neoplasm must be well cleansed and rubbed rather roughly, so as to provoke the issue of a few drops of blood. The mixture is then shaken and applied over the raw surface of the cancer by means of a brush. The solution is allowed to evaporate, and no dressing is required. The patient experiences for a few hours following the application some pain, but nothing excessive. The next day the neoplasm is completely covered with a crust produced by the action of the arsenious acid. Each day the solution is applied over the crust, which, yellow at the outset, becomes gradually brown, and finally black.

The first day the crust is firmly attached to the subjacent tissue. It is thin, but gets thicker each day until it invades all the surface of the cancer. At the end of a certain time the edges begin to rise and the separation increases each day, while a whitish serosity oozes from the ulcer.

The treatment is continued regularly until the crust is almost detached, held only by a few filaments that may be cut with the scissors. The raw surface is once more painted over with the arsenical solution, and if on the following day only a slight yellowish crust, easily detached, is observed, the ulcer will heal of itself, as all carcinomatous tissue has been destroyed. If, on the other hand, the crust is brown, resisting and adherent, the treatment must be continued until all cancerous elements have retroceded. At that period the wound commences to granulate and to heal. It must then be treated as a simple ulcer—that is to say, cleaned every day with a solution of boric acid or oxygen water, and dressed with some non-irritant powder, such as:—

Iodoform, }
Cinchona powder, }
Benzoin powder, }
Carbonate of magnesia, } 3 oz.
Ess. of eucalyptus, 2 dr.

It is remarkable that arsenious acid appears to have an elective action on cancerous elements, for, applied to simple ulcers, no crust is produced, and also after all the cancerous cells are destroyed, proving that the cure is complete

TREATMENT OF VASCULAR NÆVI.

There is good news in store for those persons, somewhat numerous, who are afflicted from their birth with vascular nævi, otherwise called wine spots or mother's mark. These stigmates, as every one knows, were always considered indelible.

Drs. Wickham, of the St. Lazare Hospital, and Degrais, of the St. Louis Hospital, presented to the Académie de Médecine a series of aquarelles of different types of these nævi, which were rendered completely colourless by the action of radium. Some belonged to adults, others to infants.

All these spots were effaced by the simple application of plane apparatus coated with a varnish in which radium was incorporated. The radiations emitted from the apparatus were dosed in such a manner that it was easy to vary the action according to the duration and number of applications.

Certain nævi can be cured by weak doses frequently repeated without producing the slightest reaction. However, in many cases where the nævi were extensive and profound, it was necessary to provoke a certain reaction. In these cases the new tissue was supple, smooth, and colourless, presenting an excellent æsthetic appearance.

The applications produce no pain, and for this reason, large surfaces can be treated and even children during sleep.

M. Wickham declared that radium can be utilised with advantage in all forms of mother's mark, even those generally considered as incurable, and the most amenable to cure are those which are most coloured and raised above the skin.

WARM BATHS FOR PNEUMONIA.

Hydrotherapy is at present employed in the treatment of acute maladies of the lung according to two methods: Cold baths and warm baths. Each of them has its partisans and its adversaries.

Hippocrates recommended warm baths in his treatise on acute affections, and Celsus advised them for all fevers.

The practice, says Dr. Dufour, fell into disuse until the beginning of the 18th century, when it was employed by empirics. But Rilliet extolled the benefits drawn from warm baths, as a sedative in bronchopneumonia accompanied with fever and delirium. D'Espine employed them systematically in bronchitis and pneumonia.

The wonderful results obtained by cold baths in the different forms of pyrexia, according to the Brandt method, caused warm hydrotherapy to be forgotten for a time. However, some ten years ago Renaut, of Lyons, rehabilitated this treatment, concurrently with Prof. Lemoine, of Lille.

There is nothing very particular in the method of administering these baths; the physician is guided as regards the number, temperature, and duration of the baths, by the general condition of the patient, the fever, the extent of the pulmonary lesions, and their more or less resistance to treatment. In average cases, a temperature of 102° to 104° F. is sufficient, the baths repeated every eight hours, each lasting fifteen minutes.

Where the general phenomena are intense with great nervous excitement, the baths should be repeated every four hours; where the pulmonary lesions are extensive as in pneumonia or in bilateral pulmonary congestion, accompanied with high fever and considerable dyspnœa, the baths should be given every four hours at 105° F. Mustard might be mixed in the morning and evening baths; one pound of ordinary mustard mixed with cold water and thrown into the bath before the hot water is poured in. While the patient is in the bath cold applications should made to the head, and a little champagne or or grog administered once or twice during the sojourn in the bath.

OPHTHALMO-REACTION.

Referring to the subject of opthalmo-reaction, it may be useful to know that Dr. Montagnon, of St. Etienne, has just published a series of cases in which the ophthalmo-reaction was abnormal. Although clearly positive in the majority of cases of well-established tuberculosis, it fails in patients suffering from bacillary cachexia, those who have reached the third stage of pulmonary phthisis, and those affected with tuberculous peritonitis.

On the other hand, the reaction is almost constant in patients suffering from typhoid fever, but entirely exempt from the bacilli of Koch. Two cases of hysteria, one of Basedow's disease, and one case of chorea responded to the same reaction.

Dr. Montagnon explains these anomalies by the fact that tuberculin is a vaso-dilator toxin, whose action is revealed under certain conditions, and it is possible that a particular condition of the vaso-motor system, or a certain degree of erethism of the nervous system, favours the appearance of these phenomena.

Oculo-reaction can, consequently, be observed in certain injections which seem to stimulate the vaso-dilator action of the tuberculin.

The phenomena resulting from oculo-reaction are complex in their nature, and are accompanied by exceptions which may be explained later on, scientifically, but for the moment one should be very prudent in their clinical interpretation.

The important practical question is: Are all patients who present reaction to the tuberculin really tuberculous? A positive affirmative in doubtful cases would be of the greatest value. Such, however, cannot be given up to the present; yet it is an acquired fact that in cases where there is little doubt on their tuberculous nature, the reaction is almost constant (85 per cent.).

A certain number of tuberculous patients present no reaction, while certain nervous and infectious conditions (typhoid fever) give a positive reaction outside all tuberculous taint.

GERMANY.

Berlin, Feb. 9th, 1908.

AT the Verein für Innere Medizin, Hr. Jul. Citron spoke on

THE SCIENTIFIC AND PRACTICAL IMPORTANCE OF OPHTHALMIC (CONJUNCTIVAL) REACTION IN TUBERCULOSIS.

He said that he had already spoken and written so much on the subject that he would only discuss certain points on which he did not agree with Hr. Stadelmann, who introduced the subject at the meeting of the Society on the 6th inst. As regarded the skin reaction, he did not attribute the importance to it that Stadelmann did. A method of reaction that, according to Pirquet, gave a positive result in 30 per cent. of healthy children of from three to five years of age, could not be of much value as regarded diagnosis in the adult. A certain value could not be denied as regarded prognosis, in so far as a negative result had any prognostic value at all. With a more delicate dosage better results might perhaps be arrived at.

The Conjunctival Reaction.—This had a close connection with that of the skin, as prompted by Pirquet's address. Wolff-Eisner introduced a drop of a 10 per cent. solution of tuberculin on to the eye-ball. Shortly after this, in the Académie des Sciences, Vallet reported the negative results of cutaneous inoculation in cattle, and Calmette the same as regarded ophthalmic inoculation. It was not worth while to discuss priority. Wolff-Eisner, from a diagnostic point of view, had unfavourable results at first, as the 10 per cent. solution used by them was too strong. The speaker had dropped in a 1 per cent. solution which gave a result that was of diagnostic value. Calmette also used a 1 per cent. solution, which, however, as it contained 1 per cent. of dry tuberculin, was ten times too strong. It was the same with the preparation obtained from the Höchst establishment. Not only must the right preparation be used, but the instillation must be done in the right way—*i.e.*, so that the drop remained in the eye, and it must be looked after at the right time, not too soon before the reaction could be begun nor too late, when it had passed off. From his observations the test was specific for most cases of tuberculosis. The result was positive in 80 to 90 per cent. of tuberculous cases, in 70 to 80 per cent. of suspected cases, and in 0 per cent., or only very rarely, in people who were not tuberculous. Not infrequently the 1 per cent. solution was not strong enough to set up the reaction, and a 2 per cent. or 4 per cent. solution was necessary. If, however, the result was not satisfactory, and a repeated application to the one eye was not advisable, he had helped things on by applying a 2 or 4 per cent. solution to the other eye. The speaker mentioned shortly the positive results that had been observed by some authors in typhoid, acute rheumatism, and syphilis. The contra-indications were of two groups, the absolute and the relative. One absolute contra-indication was disease of the eye; even if only one eye was affected, on account of the possibility of sympathetic disease. Very severe inflammations of the eye might be set up by the reaction. Scrofula was a relative contra-indication, as scrofulous people reacted with great violence. He had often seen a phlyctenular conjunctivitis after the use of the drops in such cases. Residence in a locality where trachoma was prevalent was also a relative contra-indication. In any case the individual on whom the test was made must be kept isolated for a time. The effect of tuberculin injection, after applying the test to the eye in lighting up again the inflammation that had taken place there, the speaker explained according to the views of the Wassermann school on the formation of antibodies and antigen.

Hr. L. Pick had examined the histological structure of the late papules in five cases of skin reaction. In three cases he found nothing but round-celled infiltration; in one case peculiar cells in the subcutaneous fatty tissue; and in one case typical giant cells. On a further search dead tubercle bacilli were found in the tuberculin, the giant cells being the result of their incorporation.

Hr. Noeggerath did not think that any prognostic conclusions could be drawn from the negative result of the test in severe cases of tuberculosis. In nine cases, not severe, the Pirquet test was negative, whilst subcutaneous injection gave a positive result.

Hr. S. Cohn mentioned 66 cases of typhoid (12 of his own) in which the reaction was tested with a positive result in 34 cases. Typhoid fever possibly had some relation to tuberculous susceptibility; perhaps tubercle was already present. He found no reaction in cases of diphtheria and pneumonia. He then tried whether typhoid cases reacted to non-specific extracts, and found that a positive result followed the injection of extract of bacterium coli. He had met with the same results in non-infectious cases.

Hr. Max Wolff had not met with such favourable results as other reporters. Of 19 tuberculous cases in the first and second stages, the result was positive in 12; in 18 cases of conjunctival testing the result was positive in 12. In animal inoculations he had not had one success. In 85 scrofulous children and adults, a positive result was obtained in 44 only. X-ray examination gave more frequent results as regarded tuberculosis. He had also made comparative experiments with subcutaneous injection, and the latter was far more reliable from a diagnostic point of view. After the ophthalmic reaction he had seen severe conjunctivitis.

THE CLINICAL VALUE OF WASSERMANN'S SERUM DIAGNOSIS IN SYPHILIS.

A paper on this subject appeared in the *D. Med. Wochensch.*, 52/07, by Drs. Fischer and Meier, of the Rudolf Virchow Krankenhaus, Berlin. They state that Wassermann's syphilis reaction is specific, that it has not been met with in any but syphilitic cases. If the result is a positive one, it agrees in all points with the clinical symptoms and the history. The reaction admits of a constitutional but not of an "organ" diagnosis—*i.e.*, it says only that the system is infected with the disease, but it does not say that any particular pathological process in any particular organ is syphilis. A positive result, also, only is decisive. No conclusion can be drawn from a negative result, neither as to any syphilis possibly present, nor as regards a final recovery. Treatment does not appear to influence the reaction in any way.

AUSTRIA.

Vienna, Feb. 9th, 1908.

LYMPHO-SARCOMA.

HORNER showed preparations taken from one of Schwarz's cases who died from compression and stenosis of the superior vena cava. The sarcoma lay in the anterior mediastinum region at the hilus of the lungs sending roots behind, while a portion of the growth ensheathed the vena cava producing the stenosis.

Schwarz said that a few months before death he had treated the patient with the Röntgen rays, which acted very favourably at first in reducing the size of the morbid growth. Two days after the first application the tumour went down 2½ centimetres in diameter, which apparently removed the stenosis of both the bronchi and the blood vessels, as shown by the relief to the swelling in the neck and distended jugular veins.

Later the growth had shrunk from 17 centimetres in diameter to 8 centimetres. After a pause it began slowly to increase again, but it never exceeded 10 centimetres, and remained stationary with no return of the dyspnœa and congestion of the vessels till a tooth had to be extracted, which injured the jaw, followed by infectious fever and a sudden change in the whole condition that precipitated the end.

Chiari remarked that lympho-sarcoma possessed the property of receding for a time after an operation or after an attack of fever, erysipelas, and cauterisation. He thought the Röntgen rays acted in the same way by giving a shock to the morbid growth.

ERYTHRODERMIA.

Ehrmann presented a patient who had been ill for the last nine months with erythrodermia, or what others might term pseudo-leukæmia, pityriasis rubra, etc. The physical signs were a constant, diffuse, general redness over the whole body, but less pronounced on the palmar and plantar surface and absent altogether over the genitals. The skin is œdematous and swollen. The breast and back surface are quite distended and tense with a glistening appearance. The inner surfaces of the thighs, axillæ, and elbows are greatly enlarged as with fat, and marked with a mosaic colouring combined with an irregular surface which gives it the appearance of crocodile skin. The glands of the groin, axilla, elbow, and supra-clavicular region were very tender. Nothing abnormal could be found with any of the internal organs. Injections with old tuberculin 0.01 gram., as well as the reactions of Calmette and Pirquet, failed to give any information.

The blood at the end of October gave 3,900,000 red blood corpuscles and 21,000 white; Fleischl 85 of hæmoglobin. The polynuclear and neutrophile leucocytes were 72 per cent.; eosinophile, 9 per cent.; basophile, 3 per cent.; and mononuclear eosinophile, 16 per cent.

At the end of December the red blood corpuscles were 2,800,000; white, 20,450; polynuclear neutrophile leucocytes, 55 per cent.; eosinophile, 32 per cent.; lymphocytes, 11 per cent.; while the large mononuclear leucocytes were 7.7 per cent.

Withal the pathology of this disease appears very doubtful—whether it is leukæmia or pseudo-leukæmia? Hebra was wont to group a number of these cases under the title of tubercle, but these tests all failed in the case exhibited. There is another group of cases with circumscribed patches of reddening and desquamation, which we do not place as tubercle, but which may be placed as leucocytosis. It is quite possible to confound pseudo-leukæmia and leucocytosis, as in the case brought forward, where the proportion of large and eosinophile cells preponderate. He was inclined to believe this case to be one of mycosis fungoides.

Lang said he had shown similar cases to the Society under the name of dermatitis exfoliata, although he was aware the French termed it "erythrodermie." At the beginning of this disease it is difficult to distinguish it from eczema, while at a later stage it is hard to say whether it is psoriasis or pemphigus foliacea. He could not believe, however, that it ever was associated with mycosis fungoides.

PULSATING DIVERTICULA IN ŒSOPHAGUS.

Hajek gave the history of a diverticulum in the œsophagus and the difficulty of diagnosis when pulsating. What confirmed his opinion was the passing sometimes of a small bougie into the stomach, while a large one was resisted, but sometimes would pass. The œsophagoscope and radioscope confirmed this at a later stage.

Robinsohn, who used the Röntgen rays, said a modification of the usual methods was necessary in this case. As a rule, all fluids and solids tend to enter these diverticula, but more especially the latter. With this object a capsule of bismuth, 1½ centimetres in diameter, was swallowed and subsequently observed in the sac. To guide him with the œsophagoscope he attached a thread to the capsule and measured the length of the teeth for the exact position of the instrument in order to observe the size of the opening into the sac.

HUNGARY.

Budapest, Feb. 9th, 1908.

At the recent meeting of the Budapest Royal Medical Society Dr. Stern read a paper on

Traumatic Lesions of the Skull.

In his paper he presented the following summary: 1. Injuries of the skull and brain may be classed under two heads, those of impact and those of momentum, either of which may be occasioned directly or indirectly. 2. Injuries of impact, however extensive, offer a better immediate and remote prognosis, but must be treated with as little delay as possible, and almost always surgically. 3. Injuries of momentum show graver probabilities both in their immediate and remote effects. 4. In injuries of momentum lesions through *contre coup* are more apt to occur, with extensive damage to brain structures, and often without fracture of the skull or external wound. 5. After trauma to the skull and brain, the immediate necessity is free drainage and avoidance of intracranial pressure. 6. The possibility of fracture should ever be kept in view after injuries to the head, the scalp wound should, if necessary, be freely enlarged to determine the wisdom of further operative interference. 7. Progressive coma, after momentum injuries, is a strict indication for operation.

The Complications of Polyarticular Rheumatism.

Dr. Harasfi has analysed a large number of cases, and found that about 2.2 per cent. of all hospital cases are admitted for articular rheumatism. The greatest frequency is noticed between 16 and 20 years, and the sexes are affected about equally. In 26 per cent. an angina preceded the attack, and recurrences were noticed in 39.7 per cent. Complications were noticed in 57 per cent., but more frequently among women than men. The great majority of complications (51.7 per cent.) were cardiac, and mitral insufficiency was the most frequent lesion observed. Pericarditis was observed in 1.7 per cent.; less frequently, erythema nodosum, pneumonia, chorea minor, psychical disturbances, and nephritis. The mortality was 1.7 per cent., the cause of death being pneumonia and nephritis, secondary to loss of compensation.

The Treatment of Diabetes Insipidus.

In a typical severe case of diabetes insipidus, Dr. Stein has tried a number of different therapeutic measures, with the following results:—Change in diet did not increase the amount of urine, while it made the patient very uncomfortable. Decreasing the amount of fluid ingested was also a failure, since severe nausea, vertigo, and weak pulse were the result, and the amount of urine dropped only from 10 to 8 litres. Cold baths were refreshing, but warm water, applied in the hopes of stimulating diaphoresis, was not borne well. Preparations of valerian, large doses of antipyrin, the bromides, arsenic, sodium kakodylate, mercury, and the iodides did not make a lasting impression upon the disease; but good results were finally seen from small, gradually increasing doses of strychnine, injected subcutaneously. Polyuria and polydipsia disappeared in three weeks, and the patient rapidly gained in weight.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Workmen's Compensation and Surgical Operations.—An important judgment was delivered last week by a Court of seven judges in the second division on a stated case under the Workmen's Compensation Act. A workman whose hand had been injured in the course of his employment, and who was in consequence incapacitated, received compensation under the Act. Three out of four doctors who examined him advised that the second finger of the hand should be removed, and at the same time a painful nodule in the palm. The Sheriff, holding that these were not serious operations, and that they would probably relieve the man and fit him for work, ended the compensation as the man refused to undergo them. The Court of Session upheld the Sheriff's decision. The majority of the judges were of the opinion that the workman, like any prudent and reasonable patient, who wished to be restored to health, was bound to submit to the operation, which was reasonable, and not attended by serious risk. This decision seems eminently just, and agreeable to commonsense. It is surely ridiculous to suppose that a man who will not adopt ordinary treatment to render himself self-supporting again should be allowed to receive compensation for an indefinite period.

Edinburgh University Honorary Degrees.—Among those who have been offered the degree of LL.D. by the University of Edinburgh in anticipation of the forthcoming spring graduation, are two members of our own profession, Dr. J. O. Affleck, Edinburgh, and Dr. Caton, Liverpool. Dr. Affleck is one of the best known and most highly respected medical man in Edinburgh, and has occupied very many important public positions. He is equally esteemed as a teacher, a physician, and a man, and his many friends and admirers will feel that the honour which his Alma Mater is now about to confer upon him, has never been more appropriately bestowed. The high estimation in which Dr. Caton is held by his fellow citizens is best shown by the fact that he is now chief magistrate of Liverpool—the Right Worshipful Richard Caton, M.D., Lord Mayor of Liverpool. Among other recipients of the same degree are Sir Norman Lockyer, K.C.B.; Sir James Balfour Paul, Lyon King-at-Arms; and the Rt. Hon. Thomas Shaw, M.P., Lord Advocate.

Royal Medical Society Dinner.—The annual dinner was held in the Hall of the Society on the evening of February 5th, Dr. A. C. B. McMurtrie, Senior President, in the chair. A large company gathered to meet the principal guest of the evening, Mr. Jonathan Hutchinson, London, who, after replying to the toast of his health, gave "The Royal Medical Society." In the course of his speech Mr. Hutchinson reiterated his well-known views on examinations—insisting that he would leave nothing to the caprice or individual predilections of an examiner, but would prepare lists of questions which would be put beforehand into the hands of those about to be examined. Examiners would be clumsy in their work if they could not defeat the cramming which his method might engender. Lord Salvesen and the Moderator of the Church of Scotland replied to the toasts of the sister professions, and Professors Chiene, Simpson, and Harvey Littlejohn for the University and Colleges.

Foot and Mouth Disease in Edinburgh.—A serious outbreak of foot and mouth disease was discovered in Edinburgh this week, about 80 cattle of a herd of 110 being affected. The farm is one just on the outskirts of the city, and very active measures have been necessitated. It is announced that altogether 200 cattle will be slaughtered forthwith, their carcases being disposed of by burial in the immediate neighbourhood. Meanwhile, the provisions of the Contagious Diseases (Animals) Act have been put into operation, and no movements of stock within a large district of the country are permitted. The disease has not occurred in Scotland for nearly twenty years. The present outbreak has been traced to a consignment of Dutch straw lately imported. So far, no cases of stomatitis referable to infected milk have been reported. The infected farm was in an industrial quarter of the town, from which many of the patients attending the various hospitals are drawn, but no cases suggestive of foot and mouth disease in man have been seen at the dispensary of the Children's Hospital.

Ruchill Hospital Inquiry.—The Commissioners investigating the affairs of the Ruchill Hospital brought their inquiry to a close this week. Their sittings were public, and the evidence given has been published at great length in the daily Press. Pending the appearance of the Report of the Commission, comment on the evidence (which was conflicting on several minor points) is inadmissible. On one matter, however, a word may be said. That great overcrowding of the wards was a common occurrence is admitted, and it does not seem to us that the gravity of this is sufficiently appreciated. One of the witnesses expressed the opinion that, after all, the children (for the overcrowding chiefly took place in the measles and whooping-cough wards) were better off as regards nursing, etc., than they would have been at home. Now this is very questionable. There is no doubt whatver that in diseases like measles and whooping-cough particularly, the risk of secondary infection with pneumonia and diarrhœa are very serious—so much so that in many hospitals it is the practice to isolate these diseases from uncomplicated measles. When one reads of cots so closely placed that it was difficult for the nurses to get between them, of 70 patients in wards intended for less than half the number, it is difficult to agree with the opinion that the patients did not run very grave risks indeed. But, apart from this general question, we refrain from commenting on what is *sub judice*.

BELFAST.

THE UNIVERSITY QUESTION.—A meeting of the Education Reform Association was held last week in Belfast for the purpose of demolishing, in advance, Mr. Birrell's new scheme, or rather what the members of the Association conclude the scheme will be. A group of resolutions, much too long to give here, but full of "protests," "menaces," "viewing with alarm," "outrages," "betrayals," "ecclesiastical domination," "depriving of civil and religious liberty," and such somewhat time-worn phrases, was moved by Mr. R. J. McMordie, a solicitor who was much associated with the late Dr. McKeown in educational matters. Dr. R. W. Leslie seconded, and, speaking with the knowledge of a senator of the Royal University, he said that the present state of things was absolutely deplorable. He recognised the growing strength of the feeling in favour of an Ulster University, but set himself to stem the tide by attributing its rise to a secret agitation, a faked demand, etc. The speech of the evening was made by Mr. F. Hugh O'Donnell, who supported the resolutions in a long and vigorous address. He spoke as a Roman Catholic layman, and it was exceedingly funny to hear him refer to his spiritual masters, and specially to the Jesuits, in terms which would warm the heart of the most ignorant and intolerant Orangeman in Ulster. Truly the absurdities of Irish politics surpass all belief.

PUBLIC HEALTH.—The death-rate continues high, having been 26.5 from all causes last month, including 10.4 from chest affections and 3.7 from zymotic diseases. The mortality from the latter cause was almost entirely due to measles and whooping-cough. Cerebro-spinal meningitis is apparently increasing again, though, so far, not to any alarming extent.

LETTERS TO THE EDITOR.

CHRISTIAN SCIENCE PUBLICATION COMMITTEE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am in no way anxious to start a controversy in your columns; indeed, I simply wrote in the first instance to ask to be allowed to make clear certain points which the abbreviated reports of the recent inquest had confused. I am, however, going to ask you now to permit me to reply quite briefly to Dr. Sewill.

May I say to him at once that no case was ever yet strengthened by ostentatious discourtesy. The truth about the religion of Christian Scientists is known today to too many millions of people to make gibes of the nature he employs in any way effective. Such language can only reflect on the critics who employ it.

There is in the Westminster Library a copy of "Science and Health," the fly-leaf of which is endorsed in the handwriting of one of the Abbey's great deans, as presented by Arthur Stanley. Now, no doubt, Dean Stanley knew, quite as well as Dr. Sewill, that the teaching of that book was not in conformity with the teaching of the Church of England, but I think he knew something else, which Dr. Sewill is in danger of forgetting—that you cannot define Christianity in a dogma, and that the great apostle to the Gentiles knew what he was talking about when he wrote the thirteenth chapter of the First Epistle to the Corinthians:—"Though I speak with the tongues of men and of angels, and have not love, I am become as sounding brass, or a tinkling cymbal." "And now abideth faith, hope, love, these three; but the greatest of these is love."

If Dr. Sewill believes that God is conscious of all the sufferings of humanity, ought he not to pray, and teach the patient to pray to God to remove this suffering, for, as James writes, "the prayer of faith shall save the sick," and ought he not to discountenance the ministrations (I am writing this absolutely without a thought of offence) of every doctor who is not a Christian? On his own showing, what could be more blasphemous than to call in an agnostic to destroy a disease of which God was conscious, and which He had not been prayed to destroy, or, having been prayed to destroy, had permitted to remain.

As for Dr. Sewill's objection to the term science, it is frankly amazing. The word science has a specific meaning which can be discovered by consulting a dictionary, and the use of it in the term Christian Science is absolutely justified by every philologic law.

Dr. Sewill first begs the question by assuming that disease is purely material in its origin, and so brushes aside the entire structure of idealism, as it exists quite apart from Christian Science; and then he assumes a theory of Christian Science treatment which, honestly, is quite ludicrous in its perversion of what that treatment is. There is nothing in the whole teaching of Christian Science which can be tortured into a justification of the statement "that pain and anguish can be done away with by belief in certain dogmas or creeds, and by performance of certain rites prescribed by their special ritual"; the last of these statements, indeed, is the production of undiluted imagination. Nor has any Christian Scientist ever suggested that poison could be expelled from the system by religious emotion. What they have insisted on is that when emotion comes in Christian Science disappears.

So far from Christian Scientists being blasphemous, they are attempting to show that, because Jesus was the way, the healing of what Whittier termed the seamless dress is as possible to-day as it was in His lifetime; to show that there is an answer as practical as it is beautiful to that wonderful question of Palgrave's—

"Ah, sense bound heart and blind!
Is nought but what we see?
Can time undo what once was true?
Can we not follow thee?"

It is because time does not alter truth that Christian Science, which is the effort to demonstrate truth practically, is scientific. Dr. Sewill may infer, as others have, that science is confined to the elucidation of secondary causes, and that primary causes are in "the realm of the unknowable," but the inference will never get beyond just what it is, a simple begging of the question. Christian Scientists will go on steadily and patiently, never attacking those from whom they differ, but seeking for understanding with which to demonstrate the truth of their theology, confident that Jesus was the way, and that they can follow Him.

I am, Sir, yours truly,
FREDERICK DIXON.

23 and 24, Clun House, Surrey Street, Strand, W.C.,
February 8th, 1908.

"A SURREY DOCTOR" AND VACCINATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Through a recent issue of THE MEDICAL PRESS AND CIRCULAR, a correspondent signing himself "A Surrey Doctor" put the following queries to the Editor of the *Star*. He says:—"I wish to ask him how he accounts for the fact that, with the exception, perhaps, of the extremely rare instances in which a medical man is an anti-vaccinationist, the whole of the profession take care that their own children are vaccinated? Does he believe that a man, when he becomes a doctor, is converted into an anti-human monster, capable of sacrificing his own children in a vile conspiracy for paltry, sordid gain? Does he not see that if the profession—not only in these islands, but throughout the civilised world—have the operation carried out on those they love, it must be because they, as an army of skilled witnesses, are satisfied that at least vaccination is a perfectly harmless process."

Now, it is not a fact, as here insinuated, that the instances are extremely rare in which a medical man is an anti-vaccinationist. Indeed, it can be safely said that all those members of the profession who have ever studied the subject—and they are now legion—oppose the practice of vaccination. But, even if it be assumed, just for the nonce, that the "Surrey Doctor's" interrogatories embody the facts, it tells nothing in favour of vaccination that doctors practice it on their own children; for when their infallible remedies were the now admittedly false ones of bleeding, blistering, salivating, small-pox inoculating, etc., did they not also carry these out on those they loved? They knew no better then, and, apparently, they know no better now, thus clearly showing their ineptitude for learning from past mistakes and failures.

But how medical men can still claim that to be "a perfectly harmless process" which, according to their own certifications, has killed thousands, and which even a packed Commission admitted to be inseparable from danger, is inexplicable.

I am, Sir, yours truly,
J. West.
Bradford-on-Avon, February 4th, 1908

"PRINTERS' ERRORS."

To the Editor of The Medical Press and Circular.

Sir,—You say, in your issue of February 5th, "the sole consolation we have is that the misprinted copies only reached medical men, who must have observed that there was something wrong."

Your latter assumption is no doubt right, and I, for one, at once took my pen and corrected the obvious misprint in my copy of The Medical Press and Circular, to which, from week to week, I look forward.

But in the former you are wrong, for in the work and detail which devolve on the editor, reader, and printer, and in view of the consideration you have asked for the latter two, you, Sir, may be assured of our appreciation and sympathy, not only for them, but for yourselves.

I am, Sir, yours truly,
Subscriber.

TREATMENT OF CORNS IN THE ARMY!

To the Editor of The Medical Press and Circular.

Sir,—In the letter on above subject in last issue Medical Press and Circular, the writer seems to consider that corns are altogether due to ill-fitting boots. "Five or six corns on the sole of the foot" could hardly be due to that cause? We have also heard of "corn in the ear," surely not attributable to tight boots? It is certainly novel to learn that corns on the sole of the foot act as a diaphoretic!—perhaps not the sole reason? We presume that the infantry soldier (if particular in getting his boots to fit) will have no corns whatever—the cavalryman supplied with plenty. It will certainly be altered times for Tommy Atkins when he can have his "soul" looked after both by the Army chaplain and the chiropodist, and his teeth treated as well. The writer of the letter says nothing about bunions, which are quite as likely to be caused by ill-fitting boots as corns, and have before now produced a "pilgrim's progress"!

I am, Sir, yours truly,
Observer.

MOTOR CARS FOR MEDICAL MEN.

To the Editor of The Medical Press and Circular.

Sir,—In reply to "M.D.'s" letter in your issue of January 29th last, I have been working my dispensary and private practice since February, 1906, with an 8-h.p. car, whose name I shall be glad to give privately to "M.D.," and have driven it about 11,000 miles over roads which must be about the worst in Ireland. This car is very easily driven and managed, all the vital parts are most accessible, and it is most reliable; it is very strongly made.

The seating arrangement is rather novel, three bucket seats being arranged in front in the form of a shamrock, and it can be converted into a two-seater in about ten minutes. The extra weight of the third seat is very little, which makes it much less expensive to run than if it were of the tonneau or side entrance type. The firm also fit their cars with four seats. The running expenses are well under £50 yearly. The record of these cars in the Irish and Scotch Reliability Trials has been wonderfully good.

I may say that I have no interest whatever in the firm which builds these cars.

I am, Sir, yours truly,
Gerard J. Pierse, M.D.

THE FACIAL MUSCLES IN ACHONDROPLASIA.

To the Editor of The Medical Press and Circular.

Sir,—I have recently had an opportunity of dissecting two cases of achondroplasia, and have been much impressed by the remarkable development of the muscles of the face and scalp. The individual muscles were not only strongly marked, but they formed an almost continuous stratum, by the fusion of their edges, and through obliquely-running interlacing bundles of muscle fibres. In each case the increased development was also well seen in the extrinsic muscles of the pinna and in the platysma.

The condition found in these two subjects—one male and the other female—and observations made on a living example of the disease, lead me to believe that hypertrophy of the facial muscles may possibly be a characteristic of achondroplasia. It would be interesting to learn whether other observers, clinically or in the post-mortem room, have noted a similar condition in this disease.

I am, Sir, yours truly,
A. Francis Dixon.

February 5th, 1908.

OBITUARY.

G. M. CLOWES, M.R.C.S., L.R.C.P.

We regret to announce the death of Dr. G. M. Clowes, aged 29, a son of Major Clowes, of Ilford. He had been acting as locum tenens for a medical man at Southend, and came to London with the view of taking a house appointment at the London Hospital. Some time after midnight he was found lying upon the pavement in Spital Square, Bishopsgate, unconscious, and dying from suffocation. He expired almost immediately, and at the inquest at Stepney evidence was given that death was due to suffocation by a piece of apple having lodged in the trachea. Several apples were found in one of his pockets. A verdict of "Death from accidental suffocation" was returned. Dr. Clowes had distinguished himself at the London Hospital in the junior appointments, and much sympathy is felt for his bereaved friends.

WILLIAM ALLINGHAM, F.R.C.S.

We regret to announce the death of Mr. William Allingham, who died on February 4th at his residence at Worthing, at the age of 78. Mr. Allingham became a member of the Royal College of Surgeons, England, in 1855, and a Fellow by examination in 1857, and had served on the Council of the College. He had been a tutor, demonstrator of anatomy, and surgical registrar at St. Thomas's Hospital, and Senior Surgeon of St. Mark's Hospital for Fistula, and Surgeon of the Great Northern Hospital. He was also Consulting Surgeon to the Farringdon General Dispensary and the Surgical Aid Society. He was well-known as an authority on rectal surgery, and enjoyed an extensive practice in that special line. His well-known book on "The Surgery of the Rectum," ran into five editions.

J. W. WELLS, M.D., C.M.ED., D.P.H.

WE regret to record the death, at his residence in Blackburn, of Dr. J. W. Wells, who had been suffering for some time from consumption. The deceased gentleman, who was unmarried, was a native of Blackburn, and after receiving his education at the Grammar School he went to Edinburgh University, where he graduated some 19 years ago. For three years he sat in the Council Chamber in the Conservative interest as one of the representatives of St. Andrew's Ward, being returned in 1899. He was appointed a member of the Free Library Committee in that year, and retained the position until last November, when he retired. The late Dr. Wells secured his M.B.C.M. (Edinburgh) in 1887, his D.P.H. (Manchester Victoria) in 1891, and his M.D. (Edinburgh), with commendation, in 1903. He was also a Fellow of the Chemical Society, and was known as an authority on the chemistry of cod liver oil. He had a contribution in the *British Medical Journal* on cod liver oil and cod liver oil emulsions, and another appeared in the "Manchester University Press" last year on the influence of cod liver oil on tuberculosis.

SIR JOHN DENIS MACDONALD, K.C.B., F.R.S.

WE regret to announce that Inspector-General Sir John Denis Macdonald died on Friday last at Southsea in his 82nd year. He was Professor of Naval Hygiene at the Army Medical School, Netley, from 1870 to 1880, and Inspector-General of Hospitals and Fleets from 1883 to 1886, in which year he was placed on the retired list. Educated at Cork School of Medicine and King's College Medical School, Sir John entered the Navy as Assistant-Surgeon in 1849, and in 1852 joined Her Majesty's ship *Herald* for exploring and surveying service in the South-West Pacific. In 1859, when only 33 years of age, he was elected F.R.S. He was the author of numerous scientific papers, and was created K.C.B. in 1902.

REVIEWS OF BOOKS.

INJURIES OF THE EYE. (*a*)

AT a very opportune moment appears a capital little book on injuries to the eye by Mr. Beaumont, of the Bath Eye Infirmary, for such questions are perplexing many medical men called in to advise in connection with cases arising under last year's Workmen's Compensation Act. The work deals briefly with the various Acts of Parliament under which accidents fall for purposes of legal classification, and then presents hints on the giving of expert evidence. After dealing with the eye in connection with industrial diseases, the author has a useful chapter on injuries of the orbit in base of the brain in which the eye is affected. Ophthalmic surgeons are often called upon to see cases of head injury which have been followed by blindness in one or both eyes, and the exact nature of that lesion it is often impossible to determine, but generally the injury is a retro-bulbar or intra-cranial fracture or hæmorrhage, and the prognosis is guided accordingly. Chapter III. concerns injuries to the eye-lids and lachrymal apparatus, and Chapters IV., V., and VI. those of the globe and its contents. They are all not only of a very practical nature, but are full of useful points, garnered from the author's wide experience, which are not to be met with in ordinary works on the eye, and which for the practitioners who have lost touch to a certain extent with ophthalmology are invaluable in that estimation of the extent, nature, and outcome of injuries to the eye. But most important of all is the last chapter on malingering and the various tests by which it may be detected. Malingerers, as Mr. Beaumont says, may be divided into three classes, those who pretend to have a disease which they have not; those who intentionally exaggerate the symptoms of a real disease; and those who produce a disease for the purpose of getting recompense. To detect those who have rubbed grit or coal-dust into the conjunctiva may not be a difficult task, but to detect the others is often no easy task. The amount of vision which a man has, after all, must, to a great extent, depend on subjective tests, that is to say, when there are no ophthalmoscopic changes present. The author's suggestions as to tests and probabilities reveal both experience in this difficulty and ingenuity in overcoming it, and we have ourselves picked up valuable "tips" from the perusal of his book. Snellin's test is a particularly useful addition to the medical examiner's armament, and should "floor" any ordinary impostor; but all the others are good. It is with great pleasure that we welcome this handy, clever book.

CAMPBELL'S AIDS TO PATHOLOGY. (*a*)

To compress the facts of pathology into a volume of 184 pages, and those small ones, is no easy task; but in the book before us Dr. Harry Campbell has achieved it with no small measure of success. We can readily understand that some teachers of pathology would endeavour to find fault with a book of this kind because of its compression; but, if it be used as an "aid," not as a substitute, for the larger text-book, and it enables the student to assimilate and to remember the facts he has gathered, it should be a welcome addition to the books needful for his examination. It must undoubtedly be admitted, that text-books of pathology very often serve only to confuse the student by the multiplicity of facts and theories which they contain. It is for this reason that we welcome these "aids." They supply the much-needed outline of the subject which the student can fill in as he goes along.

This book will prove specially helpful to the junior student, who is apt to feel very much at sea when brought face to face for the first time with pathological problems. A study of this small volume will clear up many of the initial difficulties which confront the student. For perusal prior to examination, Dr. Campbell's pages will be valued, as they give the salient facts in an easily remembered form. If we singled out certain portions of the book for special commendation where all is so excellent, we might refer to the sections on "Diseases of the Kidneys" and "Tumours." The portion of the book which deals with the antitoxic treatment of disease is also very valuable, and we are favourably impressed by his remarks on opsonins and vaccine-therapy. There are a number of useful engravings, which add not a little to the value of this really helpful little volume. Practitioners who have fallen behind in their knowledge of pathology cannot do better than make a pocket companion of this up-to-date skeleton, while students will find it the best *résumé* of the subject that has appeared.

BLACK'S MEDICAL DICTIONARY. (*b*)

THE appearance of the third edition of this book shows that it supplies a want among general readers. It is somewhat difficult to define the exact place of this volume in literature, for while it cannot rank as a scientific medical work of reference, on the other hand it is certainly not a popular production, using the adjectival term in its usual significance. The text has been drawn up by skilled and careful writers, and scattered through its pages are no less than 384 illustrations, most of them clear and excellent. Turning to locomotor ataxy, we find a really concise and good description of that malady, including Fränkel's much employed gymnastics. The description of "spotted fever" is equally to the point. So far as we have tested the book, its contents are trustworthy and up-to-date, and likely to be useful to that increasing class, such as nurses colonists, district visitors, journalists, teachers and others to whom a simple book of medical guidance is an acknowledged want.

(*a*) "Injuries of the Eyes of the Employed and the Workmen's Compensation Act; Problem in Progress." By W. M. Beaumont, Surgeon to the Bath Eye Infirmary. London: H. K, Lewis. 1907. Price 5s.

(*a*) "Aids to Pathology." By Harry Campbell, M.D.Lond., Bachelor of Surgery and Fellow of the Royal College of Physicians, London; Lecturer at the Polyclinic; Senior Physician, North-West London Hospital; Physician, West-End Hospital for Nervous Diseases; late Pathologist at the North-West London Hospital. Pp. 184. Fcp. 8vo. Paper, 3s. net.; cloth 3s. 6d net. London: Baillière, Tindall and Cox. 1908.

(*b*) "Black's Medical Dictionary." Edited by John D. Comrie, M.D., M.B.Edin. Third Edition. London: Adam and Charles Black. 1907. Price 7s. 6d. net.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for **The Medical Press and Circular.**

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

The Procedure to Adopt in Cases of Pregnancy Complicated by Uterine Fibroma.—P. Hardoüin (*Rennes. Archives Générales de Chirurgie*, December 25th, 1907) discusses, under this heading, the methods of dealing with such cases, and as a basis to this discussion cites a case which came under his observation of a young woman, æt. 28. Menstrual history regular and abundant, slightly tending to increase, but no metrorrhagia. Married for six months; and pregnant two months, with usual signs of early pregnancy. Supervening upon these, other symptoms of a grave nature appeared—constipation and frequency of micturition, pains in the pelvis radiating to thighs and lumbar region. On palpation a tumour the size of a fœtal head at term, rising two finger-breadths out of the pelvis and incorporated with the uterus, which, on vaginal examination, was found retroverted and incarcerated. It was decided to operate. This was done by Professor Dayot, assisted by M. Hardoüin. The tumour, which proved to be a fibroid attached to the front of the uterus, was enucleated, the bed of the cavity being in part formed by the mucous membrane of the inside of the uterus. The uterus was reposed, and the wound closed by deep sutures. Hæmostasis was difficult, and had ultimately to be assisted by two gauze wicks which were brought through the abdominal wound. Recovery was uneventful, and delivery accomplished at term by the means of forceps, the head being delayed at the perinæum. The questions arising are: Ought we to interfere in cases of this kind by operative measures or by induction of abortion? Again, if the patient is in labour, what would be the best procedure? The writer warns the medical man against a false idea as to the number of cases in which difficulty arises, and quotes statistics. To sum up his ideas of procedure in cases where pregnancy or labour is complicated by uterine fibromas:—I. During Pregnancy.—(1) In cases where no grave symptoms exist, especially incarceration. In the vast majority of cases there is no indication for doing anything. Should the situation of the tumour be recognised as one likely to cause complications in labour, myomectomy should be performed. (2) Where grave symptoms exist. Leaving aside torsion and suppuration of a fibroid, which rarely call for intervention. The accidents arising from incarceration will be dealt with. Here the surgeon ought to interfere, but the interference depends on several things:—(*A*) The fœtus not being viable. Three proposed methods: (*a*) induction of abortion; (*b*) abdominal hysterectomy; (*c*) myomectomy. Induction of abortion: everywhere rejected; to quote Delagénière, "infinitely more serious than all the radical operations." Abdominal hysterectomy, total or sub-total, easy of execution, and rapid, but sacrifices the infant, and, of course, prevents further child birth. Myomectomy: more complicated than hysterectomy, but the method of election in all cases of pedunculated fibroids, and can also be employed as we have shown in sessile fibroids. Abortion sometimes follows upon the traumatism, but infection of peritoneum is of a mild nature, as a rule. (*B*) When the fœtus is at or near term. In this case he believes the method of choice to be abdominal hysterectomy, the result being advantageous to mother and child. II.—During Labour.—(1) When the tumour does not lie below the pelvic brim: await spontaneous labour; (2) when the tumour fills up part of the genital canal: (*a*) push up the tumour with the hand above the brim; (*b*) if this manœuvre fails, perform Cæsarean section; this will seldom be conservative; it will be the first step to supra-vaginal amputation.

H.

The Prevention of Ophthalmia Neonatorum.—Griffith, London (*British Medical Journal*, February 1st, 1908), discusses the methods of procedure, but believes that the most efficacious method is the careful washing of the eyelids when the head is born and before the child opens its eyes, then later on to use the nitrate of silver solution. Should irritation of the lids arise as a result of the silver nitrate, he advocates the use of a few drops of castor-oil placed between the lids.

H.

Rôle of the Gonococcus in Disease.—Taylor (*Amer. Jour. Obst.*, Jan., 1908).—The accumulated knowledge presented in this paper shows that the gonococcus is one of the most formidable microbes met with in pathology, and takes a high place with those of syphilis and tuberculosis. The following is a summary of its activities:—(1) It attacks the human urethra, and there gives rise to both a catarrhal and hyperplastic inflammation, from which may follow chronic urethritis and a tendency to stricture. (2) By contiguity of tissue it invades the testes and their appendages, and thus threatens sterility in men. (3) Limited in its effects, as a rule, to the sub-epithelial connective tissue layer, it in some cases by further invasion gains a foothold in the venous and lymphatic radicles of the male and female genitalia, and produces local and general disturbances. By this extension the whole organism may be more or less seriously attacked, and local disorder, much suffering and disability may result. The gonococcus then becomes a true factor of septicæmia, and serious and even mortal illness is to be feared. Arthritis and rheumatism are the most constant concomitants of gonorrhœal invasion, and induce marked changes in the joints, the tendons, the bursæ, and the muscles. (4) Such is the anti-toxic power inherent in the blood serum, that in very many cases, even when vital parts are attacked, the gonococcus is destroyed; but, on the other hand, by reason of its toxins, or perhaps of the microbe itself, more or less structural change is produced in the cerebro-spinal system, which may be local or generalised. (5) The question as to whether an inhibitory serum may be produced to kill or jugulate the virulent microbe is still unsettled. (6) While the gonococcus may become latent, and may hibernate in tissues, crypts, and follicles, it may at any time become potential. It also may lead to mixed infection, and prepare the soil for other microbes which may run a severe course.

F.

The Supports of the Pelvic Viscera: A Review of Some Recent Contributions to Pelvic Anatomy.—Fothergill (*Jour. of Obst. and Gyn.*, Jan., 1908).—The following is a summary of the conclusions arrived at in this paper:—(1) The so-called ligaments of the uterus lie loosely upon the subjacent structures, and have no supporting action. The broad ligament is simply a mesovarium and meso-salpinx. The utero-sacral and utero-vesical folds are incapable of resisting downward pressure, as is the round ligament, which, moreover, is a vestigial structure (gubernaculum ovarii et uteri). (2) The external muscular layer of the pelvic floor has a sphincteric rather than a supporting action. The internal muscular layer of the pelvic floor being the degenerated representative of the tail muscles of lower animals, has largely lost its muscular action, and the lower part of the levator ani merely acts as an adjuvant to the sphincters of the rectum and of the vagina. (4) The classical description of the pelvic fascia should be given up, and the fascia should be regarded as the sheath of the muscles, the vessels, and the viscera. (5) The internal muscular layer, with its fascial investment, forms the funnel-shaped pelvic diaphragm. (6) The pelvic diaphragm does not support the pelvic organs by its muscular action; it could not do so in virtue of its shape, were they not firmly attached to its sloping lateral walls. (7) This attachment is accomplished by the fibrous sheath of the blood vessels and accompanying structures, which supply the pelvic viscera. The one constant essential cause of prolapse is relaxation of the perivascular sheaths. (8) The rectum has attachments to the back of the pelvis quite distinct from those of the urino-genital organs to its sides. It does not descend with them in prolapsus. When the anterior rectal wall descends in rectocele, it is united with the posterior vaginal wall by cicatricial tissue, the result of infection during the healing of perineal tears. F.

Prevention of Peritoneal Adhesions by Adrenal Salt Solution.—Marvel (*Amer. Jour. Gyn.*, Jan., 1908).—The tendency of peritoneal adhesions to re-form after operation is very marked. An exudate of blood and lymph is poured between the raw surfaces, which, if permitted to fall together, immediately unite. Adhesions are more likely to form when the exudate is of high density. On the other hand, when the exudate into a fluid is of low density, adhesions are not formed. It is therefore desirable to dissolve the exudate into a fluid of low density, and saline solution is a most excellent agent for that purpose. The addition of adrenalin to the solution has the advantage of constricting the blood vessels and preventing further oozing. Marvel uses a quart of normal saline solution with one drachm of adrenalin chloride solution at a temperature between 100° and 110°. The advantages claimed for this solution are, that its bulk keeps the separated surfaces apart, that it dilutes the exudate from the peritoneum, that it prevents further oozing, and finally that it counteracts thirst and shock. F.

Purulent Ophthalmia Neonatorum of Intra-Uterine Origin.—Holzbach (*Monatschrift für Geb. und Gyn.*, Bd. 27, Hft. 1) states that owing to the prophylactic measures adopted, gonorrhœal ophthalmia neonatorum is rarely seen in maternities, that when it does arise it is usually of a mild character, but that we must still confess that it is quite impossible to completely prevent it. Statistics reveal that most cases appear on the third day after labour, and that the incubation period is normally three days. Most infants were therefore infected during the final stages or at the end of labour. Those cases in which the disease appeared on the first and second days after labour were ascribed to a particularly rapid progress of the disease, but that the infection may occur in the uterus itself is proved by the not inconsiderable number of cases in which infants have been born with marked signs of inflammation. The author describes a case which induced him to write this paper. The membranes had ruptured nearly four days before the child was born. There was a purulent discharge from both eyes, the right cornea was clouded, and on the left in addition to the cloudiness was a large ulcer. On the next day an ulcer began to show itself on the right cornea. Gonococci were present in the secretion from each eye. Consideration of the cases which have been already recorded shows that in nearly every case the membranes had been ruptured for several hours before the child was born. The author concludes that purulent ophthalmia of intra-uterine origin is to be regarded as due to contact-infection which may arise when the membranes rupture at any place, the bacteria ascending from the vaginal secretion, or being directly implanted in the eyes from the adjacent walls of the cervical canal. All cases of premature rupture of the membranes therefore indicate special care in applying the prophylactic treatment of ophthalmia, as in these cases only immediate instillation can help. Finally, as the children of mothers suffering from gonorrhœa are usually badly developed, and not very capable of resisting any injury during the first weeks of life, the prognosis of purulent ophthalmia of intra-uterine origin must be regarded as particularly unfavourable. G.

MEDICAL NEWS IN BRIEF.

Harveian Society.

AT the annual general meeting, held at the Society's rooms, the following officers were elected for the ensuing year:—

President: Mr. D'Arcy Power, F.R.C.S.

Vice-Presidents: Dr. G. A. Sutherland, Dr. C. Buttar, Dr. H. J. Macevoy, Dr. W. H. Blenkinsop.

Treasurer: Mr. Francis Jaffrey.

Honorary Secretaries: Mr. T. Crisp English, Dr. W. H. Willcox.

Council: Dr. G. A. Barton, Sir John Broadbent, Bart., M.D., Mr. A. C. Butler Smythe, Dr. F. W. Cock, Dr. Elliot, Mr. Laming Evans, Dr. A. James, Mr. Lawrence Jones, Mr. E. L. Payne, Dr. Sidney Phillips, Dr. H. A. Sansom, Mr. Campbell Williams.

The following programme has been arranged:—

February 13th.—"The Diagnosis and Treatment of Abdominal Injuries," by Mr. Maynard Smith, F.R.C.S.; "The Treatment of Bronchial Asthma by Inoculation with a Bacterial Vaccine," by Dr. Carmalt Jones.

March 5th.—Dr. Samuel West will open a discussion on "The Treatment of Pneumonia."

March 26th.—Harveian Lecture by Sir Almroth Wright, M.D., F.R.S., "Some Points in Connection with Therapeutic Immunisation."

April 9th.—"The Surgical Treatment of the Incompletely Descended Testis," by Mr. L. B. Rawlings, F.R.C.S. Clinical cases will also be shown.

May 7th.—Clinical Evening at the Paddington Green Children's Hospital.

Examinations in Hygiene.

A SERIES of examinations in hygiene has been promoted and organised by the Incorporated Institute of Hygiene of London, which should stimulate the acquisition of knowledge in regard to those important subjects which affect the health and well-being of the people, and which may be expected also to have most beneficial and far-reaching results on the physical fitness of the race.

These examinations will be held at the leading centres throughout England, Scotland, and Ireland, and are of special interest to ladies, as they will include not only the necesary examination showing general proficiency in hygiene, but the following additional Honours subjects, viz.:—The Hygiene of the Home; The Hygiene of Motherhood; The Feeding and Rearing of Children; Food and Cooking; Home Nursing and First Aid; School Hygiene; Physical Training.

The future heads of households are those to whom this syllabus more particularly appeals, and there is no doubt that the young ladies of this country have still much to learn in connection with personal and domestic hygiene before their own health receives the attention it deserves, and the hygiene of our homes can be greatly improved.

Nursing and the needs of the invalid, and the feeding and rearing of children are subjects which are not unworthy of being placed in the forefront of a girl's education, as they are likely to be of far more practical use in her daily life than many branches of study which now receive an attention out of proportion to their value. The prevalent ignorance in regard to child life is one of the chief causes of infant mortality, and not until this ignorance is removed and the duties and responsibilities of motherhood are more fully recognised, can we expect any serious amelioration of the present sad state of affairs.

An Examining Board, composed of some of the leading physicians and scientists throughout the country has been formed to further this branch of the educational work of the Institute of Hygiene, and every assistance and encouragement will be given to candidates, who may carry on their studies at school, college, or at home, while they will receive the certificate of the Institute for proficiency in elementary knowledge, and the diploma of the Institute for proficiency in advanced knowledge should they pass the examination successfully.

Metropolitan Asylums Board.

AN ordinary meeting of the managers of the Metropolitan Asylums District was recently held at the offices of the Board, Mr. J. T. Helby, the chairman, presiding. A letter was read from Lieutenant L. Menzies, R.N., resigning his appointment as chief officer of the training ship *Exmouth*. Reporting upon an application jointly signed by the several medical superintendents in the hospitals' service for an increase of their remuneration, the Hospitals Committee stated that the salary assigned at present to a medical superintendent begins at £400 and rises annually by £25 to a maximum of £700 per annum, with certain emoluments. In recent years the work of the Board's hospitals had grown both in volume and importance. Comparing the past with the present, it was found that the proportion of notified cases admitted to hospitals had increased from 65.5 per cent. in 1898 to 84 per cent. in 1906, which was mainly due to the confidence the public had in the efficiency of the Board's arrangements for the care of the infectious sick. The medical superintendents were a body of men who were constant in their endeavours to co-operate with the Board in carrying out the important duties which were laid upon them. The committee were of opinion—(a) that the minimum salary of a medical superintendent was too low; (*b*) that seeing it took 12 years as against four years in the Board's asylums service for a medical superintendent in the hospitals' service to reach his maximum, the rate of increment should be accelerated; and (*c*) that the maximum did not adequately represent the value to the Board of a medical superintendent of experience. They submitted a revised scheme under which the rate of increment will be accelerated and the maximum salary increased to £800 per annum. Notice was given that its adoption would be moved at the next meeting.

Poor-Law and Sanitary Legislation in Ireland.

TWO questions of interest to medical men in Ireland were asked in Parliament during the past week. On February 4th Mr. Fetherstonhaugh asked the Chief Secretary to the Lord Lieutenant of Ireland whether it was intended to introduce any legislation during the present session to give effect to the report of the Commission on the Irish Poor-Law Administration, and in particular to deal with the grievances of the Irish Poor-Law medical officers.—Mr. Birrell replied that it was the intention of the Government to introduce legislation to amend the Irish Poor-Laws, but that he could not hold out any hope that an opportunity will arise during the current session.

The following day Mr. Augustine Roche asked the Chief Secretary to the Lord Lieutenant of Ireland whether, in view of the unanimous expression of public opinion all over Ireland during the past six months on the urgent necessity of taking steps to check the ravages of consumption in Ireland, any action would be taken this session to amend the law in conformity with the views expressed at the meetings.—Mr. Birrell replied that it is intended to introduce a Bill on the subject referred to in the question. The Bill, which has been drafted, is entitled, "The Tuberculosis Prevention (Ireland) Bill, 1908." He hoped it would pass into law during the present session.

Sanatorium for Cheshire.

MUCH regret has been expressed in Cheshire at the refusal of the County Council to accept from an anonymous donor the gift of Oakwood Hall, a splendid estate at Romiley, as a sanatorium for tuberculous patients. Many authorities are anxious to secure the gift. The Councils of Chester, Stockport, Birkenhead, and Crewe are combining to approach the donor through Dr. Hewitt, of Northwich, requesting that the offer may be made to them.

IT has been decided, at an extraordinary meeting of the Chelsea Board of Guardians, to ask for a Local Government Board inquiry into the management of the Poor-Law Infirmary. This proposal has arisen from the recent scandal connected with the death of a patient who had been left unattended in the bathroom for several hours.

Royal College of Physicians—New Licentiates.

AT the quarterly Comitia of the Royal College of Physicians, held on January 30th, licences to practice were conferred upon the following 68 gentlemen who have passed the final examination of the Examining Board in England in Medicine, Surgery, and Midwifery, and have complied with the by-laws of the College:—

Alexander C. Anderson, Charles E. Anderson, Arthur G. Atkinson, B.A., Tobias R. H. Blake, B.A., Harry Blakeway, B.Sc., Stanley L. Brimblecombe, John P. Buckley, B.A., William A. Burr, M.D., Howard J. B. Cane, B.A., Ernest P. Carmody, Arthur J. W. Cunningham, B.A., Sidney T. Davies, Bernard Day, B.A., Arthur F. W. Denning, Alban Dixon, John McD. Eckstein, John Everidge, Arthur L. Foster, Herbert Gall, Eric W. Gandy, B.A., Eric G. Gauntlett, William Gilliatt, Harold D. Gillies, Gathorne R. Girdlestone, B.A., Alexander E. Gow, John L. Graham-Jones, B.A., Archibald Hamilton, B.A., Charles T. Hawkins, Claud A. Holburn, Nelson W. Jenkin, B.A., Gordon Ley, Edward L. M. Lobb, Dermot Loughlin, Alexander T. McCaw, Donald Macrae, Claude H. Marshall, John B. Martin, Thomas M. Miller, Roderick J. G. Parnell, Eustace M. Parsons-Smith, Hubert Pinto-Leite, B.A., Horace J. D'A. G. Price, Robert B. Price, Joseph F. E. Prideaux, Edward J. J. Quirk, Percy C. Raiment, Roland W. Rix, Harold T. Rossiter, Mulk Raj Sawhney, Francis C. Searle, Leonard W. Sharp, B.A., Charles H. Smith, M.B., Frank H. Stephens, Hugh Stott, Gilbert F. Syms, Wilfred R. Taylor, Ernest W. Toulmin, Nusserwanji Hormasji Vakeel, Cuthbert F. Walker, B.A., Alan G. Wells, Ernest G. Wheat, James N. Wheeler, B.A., Edward B. C. White, William C. Wigan, Cyril O. O. Williams, Rajaiya R. Williams, L.R.C.P. and S. Edin.; John S. Williamson, William L. R. Wood, L.S.A.

Diplomas in Public Health were also granted (in conjunction with the Royal College of Surgeons) as follows:—Robert C. T. Evans, L.S.A., Ernest E. S. J. Galbraith, L.R.C.P. and S. Edin., L.F.P. and S., Glas.; William H. Hillyer, M.D., Dur., L.R.C.P., M.R.C.S.; Wharram H. Lamplough, M.D., B.S., Dur., L.R.C.P., M.R.C.S.; Arthur R. Litteljohn. L.R.C.P., M.R.C.S.; James Mair, M.B., C.M.; Fairlee R. Ozzard, Major I.M.S., L.R.C.P., M.R.C.S.; George E. F. Stammers, Captain R.A.M.C., L.R.C.P., M.R.C.S.; James B. Stephens, M.B., B.S., Lond., L.R.C.P., M.R.C.S.; and John Tate, L.R.C.P., M.R.C.S.

Royal Army Medical Corps.

THE successful candidates for commissions in the Royal Army Medical Corps at the recent examination in London, for which 64 candidates entered, were as follows:—

J. James, M.B., B.S.Lond., 614 marks; H. H. Blake, M.B., B.S.Durham, 583; A. C. H. Suhr, M.B.Cantab, 577; W. J. Dunn, M.B. Ch.B., B.A.O.Univ.Dublin, 576; J. E. Ellcombe, M.R.C.S.Eng., 575; B. Varvill, M.R.C.S.Eng., 565; F. B. Dalgliesh, M.R.C.S.Eng., 560; A. G. Wells, M.R.C.S.Eng., 559; G. J. Keane, M.D., 554; F. H. Bradley, M.B.Edin., 553; R. M. Dickson, M.B., Ch.B., 553; F. Worthington, B.S., B.A.Cantab, 548; C. M. Rigby, M.R.C.S.Eng., 545; A. L. Stevenson, M.B.Univ.I., 545; M. Leckie, M.R.C.S.Eng., 535; S. G. Walker, M.B., 534; C. E. L. Harding, M.B.R.U.I., 533; A. Shepherd, M.B., Ch.B.Aber., 526; W. J. Tobin, L.R.C.P. and S.I., 522; L. Murphy, L.R.C.P. and S.Edin., 516; A. H. T. Davis, M.R.C.S.Eng., 515; W. H. S. Burney, M.R.C.S.Eng., 512; A. L. Foster, M.R.C.S.Eng., 512; J. W. Houston, M.B., Ch.B., 510; T. S. Eves, M.B., Ch.B., 507; R. O'Kelly, L.R.C.P. and S.I., 505; F. M. Hewson, L.R.C.P. and S.I., 503; C. McQueen, L.R.C.P. and S.I., 496; A. E. G. Fraser, M.R.C.S.Eng., 495; J. S. McCombe, M.B.Univ.I., 495.

Apothecaries Hall of Ireland.

AT a special meeting of the Court held on Monday, February 3rd, the following candidates, having passed the necessary examinations, were admitted Licentiates in Medicine, Surgery, Midwifery, and Pharmacy of the Apothecaries Hall of Ireland:—Synott Valentine O'Connor and John Hargreaves Robinson.

NOTICES TO CORRESPONDENTS, &c.

☛ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. Half Page, 13 insertions, at 35s.; 26 at 32s.; 52 at 30s. Quarter Page, 13, at 18s.; 26 at 16s.; 52 at 15s. Eighth Page, 13, at 9s.; 26 at 8s.; 52 at 7s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Enquirer (Co. Clare).—You had better apply to Dr. G. L. Eastes, Laboratories of Pathology and Public Health, 38, New Cavendish Street, London, W. There is a regular tariff, which may be had on application to him

Respice Fimen.—Our correspondent's letter, we regret to state, is too long for insertion, owing to the crowded condition of our columns.

A FAMILY OF DOCTORS.

The late Dr. John Trotter, of Choppington, was a member of an old Scottish county family, with a remarkable trait of character. His father, grandfather, and great-grandfather all adopted the medical profession, and he himself was the last surviving son of a family of doctors. "All the Trotters must be doctors," used to be a family saying The deceased gentleman was born in Kirkcudbrightshire. The family went to Blyth in 1865, Dr. Alex. Trotter founding an extensive practice there, Dr. James Trotter settling at Bedlington, and Dr. John Trotter at Choppington.

R. S.—Messrs. Allen and Hanbury were undoubtedly the first chemists to prepare and place upon the market trypsin in solution for hypodermic injection. The preparation was introduced upon the suggestion of Dr. Shaw-Mackenzie, and a sample of it was forwarded to Edinburgh for experimentation upon cancerous mice. "Honour to whom honour is due."

Robert Bacon.—The contribution is scarcely suitable for the pages of a medical journal, otherwise we should have been pleased to publish it.

Meetings of the Societies, Lectures, &c.

Wednesday, February 12th.

Royal College of Surgeons of England.—5 p.m.: Dr. J. W. H. Eyre: The Importance (Surgically) of the Pyogenetic Activities of Diplococcus Pneumoniæ. (Erasmus Wilson Lecture.)

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. H. L. Barnard: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. R. H. J. Swan: Carcinoma of the Breast, its Early Recognition and Treatment.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Cliniques: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

Great Northern Central Hospital (Holloway Road, N.).—2.30 p.m.: Surgical In-patients (Mr. Stabb); Medical Out-patients (Dr. Horder); Gynæcological (Dr. Lockyer); Skin (Dr. Whitfield); Teeth (Mr. Baly); Operations (Mr. Stabb).

Thursday, February 13th.

Royal Society of Medicine (Obstetrical and Gynæcological Section) (20, Hanover Square, W.).—7.45 p.m.: The President, Dr. Macnaughton-Jones, Dr. E. Holland, and Dr. A. Routh: Specimens. Dr. R. Andrews and Dr. D. Maxwell: A Case of Difficult Labour, with Remarks on the Specimen of the Frozen Section of the Uterus. Dr M. Randall: An Ovarion Dermoid with Secondary Cysts connected with the Omentum, with Pathological Report and Remarks by Mr. T. W. P. Lawrence.

Ophthalmological Society of the United Kingdom (11, Chandos Street, Cavendish Square, W.).—8 p.m.: Clinical Evening: Mr. L. Paton, Mr. J. S. Hosford, Dr. F. W. Edridge-Green, Mr. J. H. Fisher, and others: Cases and Demonstrations. 9 p.m.: Discussion of the Cases.

United Services Medical Society (Royal Army Medical College, Millbank, S.W.).—8.30 p.m.: Dr. Pembrey: The Physiological Principles of Physical Training.

Harveian Society of London (Stafford Rooms, Tichborne Street, Edgware Road, W.).—8.30 p.m.: Mr. M. Smith: The Diagnosis and Treatment of Abdominal Injuries. Dr. C. Jones: The Treatment of Bronchial Asthma by Inoculation with a Bacterial Vaccine.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. J. E. Squire: Pneumothorax.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Throat Operations (Mr. Carson).

Great Northern Central Hospital (Holloway Road, N.).—2.30 p.m.: Medical In-patients (Dr. Morison).

St. John's Hospital for Diseases of the Skin (Leicester Square, W.C.).—6 p.m.: Lecture:—Dr. M. Dockrell: Treatment (Constitutional and Local in all its Forms).

Hospital for Sick Children (Great Ormond Street, W.C.).—4 p.m.: Lecture:—Mr. Corner: Injuries and Diseases of the Epiphyses.

Friday, February 14th.

Royal Society of Medicine (Clinical Section) (20, Hanover Square, W.).—8.30 p.m.: Dr. L. Guthrie and Mr. S. Mayou, Mr. J. P. Roughton, Dr. H. French, Mr. R. J. Godlee, Dr. S. Taylor, Dr. A. Latham, and Dr. F. P. Weber: Exhibition of Cases. Dr. F. G. Batten and Dr. J. G. Forbes: Note on a Case of Gaertner Infection in an Infant. The patients will be in attendance at 8 p.m.

Royal College of Surgeons of England.—5 p.m.: Mr. L. S. Dudgeon: Infection of the Urinary Tract due to Bacillus Coli. (Erasmus Wilson Lecture.)

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Dr. St Clair Thomson: Clinique. (Throat.)

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques: Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. M. Leslie). 4.30 p.m.: Demonstration:—Mr. R. P. Brooks: Selected Eye Cases.

Great Northern Central Hospital (Holloway Road, N.).—3.30 p.m.: Lecture:—Mr. G. B. M. White: Urethral Stricture.

Appointments.

Bird, W. E. F., M.R.C.S., L.R.C.P.Lond., Medical Officer to the York Post Office.

Charles, Herbert, M.R.C.S., L.R.C.P.Lond., Anæsthetist to the Paddington Green Children's Hospital.

Collier, James, M.D., F.R.C.P.Lond., Physician in Charge of Wards to St. George's Hospital.

Edington, G. H., M.D.Edin., F.F.P.S.Glasg., Assistant to the Professor of Clinical Surgery, University of Glasgow.

Jardine, Robert, M.D.Edin., M.R.C.S.Edin., F.F.P.S.Glasg., F.R.S.E., External Examiner in Obstetrics to the Victoria University, Manchester.

Maynard, Edwin, F.R.C.S.Eng., L.R.C.P., D.P.H.Lond., Senior House Surgeon at the Bristol General Hospital.

Mudge, Zachary Belling, L.R.C.P.Lond., M.R.C.S., Medical Officer of Health for the Hayle (Cornwall) Urban District Council.

Stevenson, Thomas Henry Craig, M.D., B.S.Lond., L.R.C.P. Lond., M.R.C.S., D.P.H.Cantab., Chief Medical Inspector of Schools by the Somerset County Council.

Vacancies.

Joint Counties Lunatic Asylum, Carmarthen.—Second Assistant Medical Officer. Salary, £160 per annum, with board, lodging, washing, and attendance. Applications to W. Morgan Griffiths, Solicitor, Clerk to the Visitors, Carmarthen.

Nottingham City Asylum.—Second Assistant Medical Officer. Salary, £150 per annum, with board, apartments, etc. Applications to the Medical Superintendent.

Kent County Asylum, Maidstone.—Male Fourth Assistant Medical Officer. Salary, £175 per annum, with furnished quarters, attendance, coals, gas, garden produce, milk, and washing. Applications to the Medical Superintendent.

County Borough of Brighton.—Medical Officer of Health. Salary, £600 per annum. Applications to Hugo Talbot, Town Clerk, Town Hall, Brighton.

Mullingar District Lunatic Asylum.—Resident Junior Assistant Medical Officer. Salary, £100 per annum, all found. Applications to Chairman, District Asylum, Mullingar.

Lindsey County Council, Lincolnshire.—County Medical Officer of Health and Chief Medical Inspector of School Children. Salary, £400 per annum, with necessary out-of-pocket travelling expenses, office and clerical assistance. Applications to Chas. Scorer, Clerk of the Lindsey County Council, Stonebow, Lincoln.

Norfolk County Council.—Medical Officer of Health. Salary, £500 per annum. Applications to G. Christopher Davies, Clerk to the Norfolk County Council, The Shirehouse, Norwich.

Births.

Anderson.—On Feb. 2nd, at Newholme, Pittorbury, the wife of John Anderson, M.B., C.M.Edin., of a daughter.

Marriages.

Eeles—Wolfe.—On Feb. 5th, at St. Mark's Church, Marylebone Road, London, Francis Carolus Eeles to Mary Hall, daughter of the late J. R. Wolfe, M.D., F.R.C.S.E., Glasgow.

Deaths.

Macdonald.—On Feb. 7th, at 42, Granada Road, Southsea, Inspector-General Sir John Denis Macdonald, K.C.B., R.N., F.R.S., M.D., in his eighty-second year.

Rowntree.—On Feb. 6th, at 31, Fellows Road, Hampstead, of acute pneumonia, William Augustine Rowntree, M.B., B.Ch., aged 37.

OXO

for Influenza cases.

OXO is digested without effort. It is most valuable for patients recovering from Influenza. It embodies both the extractives and fibrine of beef, and is absolutely pure and safe.

Doctors can prescribe OXO with confidence, knowing that the makers have their own farms and cattle.

Liebig's Extract of Meat Co., Ltd. Est. 1865.
Pioneers in the manufacture of concentrated foods.
Makers of LEMCO and OXO.
4, Lloyd's Avenue, London, E.C.

Avoid adulterated substitutes by prescribing "OXO" by name.

We ask the favour that Physicians will prescribe—

"LIQUOR CARBONIS DETERGENS"

(REGISTERED TRADE MARK)

(WRIGHT'S)

The necessity for this request is made apparent in the "Chemist and Druggist," which says—

"The B.P. preparation (Liq. Picis Carbonis) is, it should be noted,

MUCH BEHIND THE ORIGINAL

and differs from it in composition, and therefore in efficacy. We call the attention of Dispensers to this point because it seems natural to suppose that when the B.P. imitates an article such as 'Liquor Carbonis Detergens' it is not immoral to substitute the official preparation for the proprietary one. This is, of course, absurd, because the compilers of the British Pharmacopœia have

NO MORE RIGHT TO INFRINGE

other people's proprietary rights than the man in the street."

FORTY YEARS' REPUTATION.

WRIGHT, LAYMAN & UMNEY, Ltd.,
SOUTHWARK, LONDON.

"I like the idea of the Two Irons in Hemaboloids"

was the comment of a physician to whom this preparation was presented, and this peculiarity is worthy of special note.

Each Tablespoonful of Hemaboloids contains an amount of iron equal to that contained in 20 minims (1.33 c. c.) Tr. Ferri Chlor.

1. The larger part of the iron in Hemaboloids exists in organic combination with the necleo-proteids obtained from vegetables rich in iron.
2. This vegetable food-iron is reinforced or "ferrated" with a less resistant organic iron compound, in order to more readily neutralize the sulphur-bearing compounds in the bowel, thus preventing the destruction and permitting the absorption of the food-iron in Hemaboloids, as well as that contributed by the daily food supply.

Dose: One Tablespoonful 3 or 4 times a day, Children in proportion.

ANDRUS & ANDRUS
46 Holborn Viaduct, London, E. C.

SUPPLIED IN 12 OUNCE BOTTLES.

"Little
and
Good"
LEMCO

In purity "Lemco" stands pre-eminent. It is better and more uniform than home-made beef tea. Doctors rely on it. They know "Lemco" is prepared from cattle certified to be free from tuberculosis; that it is untouched by hand and watched by experts at every step of its preparation; and finally every single batch when finished is analysed by Dr. Voit and Dr. Rubner before being put on sale. It is absolutely pure and safe. Always prescribe it as "Lemco."

"Lemco," 4, Lloyd's Avenue, London, E.C.

THE TUBERCULOSIS PROBLEM.

Given the Sociological Conditions of Sanatoria and Medico-Dietetic Conditions of "MIOL," there is evidence arriving daily from medical men that MIOL will satisfactorily combat tubercular Disease.

"Miol"

"MIOL" IN PULMONARY DISEASE—The air passages are relieved from the obstructive morbid secretions; breathing is soon restored to the normal. Hæmoptysis is at once arrested, night sweats stop in about three days, the irritating cough is speedily removed.

The foul-smelling septic condition is corrected by the antiseptic action of the contained free Iodine, and the whole series of morbid symptoms are removed.

"MIOL" is a nutritive tonic and stimulant promoting the functional activity of all the organs of the body as well as being the most active digestive of its kind known to Science.

MOST PALATABLE. CHILDREN LIKE IT.

"MIOL" is being rapidly established in all the principal Hospitals and Sanatoria.

Send for booklet and sample with actual Clinical Reports obtained by Medical Men from Patients.

Will the Doctor kindly—

(1) Weigh each case before taking "MIOL," and each fortnight afterwards?

(2) Examine the sputa and blood before and after taking "MIOL" for Tubercle Bacilli?

(3) Note temperature, sweating, appetite and digestion before and after beginning "MIOL" from time to time?

Samples and Clinical Reports on application.

LACTOPEPTINE

IN POWDER AND TABLETS

DOSE MEASURE
FOR INDIGESTION
FOR DYSPEPSIA

LACTOPEPTINE
Registered.

LACTOPEPTINE contains the five active agents of digestion, combined in the same proportion as they exist in the human stomach, and will digest food in a manner identical to that obtained under the influence of the natural gastric juice.

LACTOPEPTINE will be found far superior to all other remedies in Indigestion, Dyspepsia, and kindred diseases.

Also, particularly indicated in Anemia, General Debility, Chronic Diarrhœa, Constipation, Headache, Vomiting and Nausea in Pregnancy, and Impoverished condition of the blood.

PRICE 4/6.

PREPARED SOLELY BY
JOHN M. RICHARDS,
46, Holborn Viaduct
(Late Gt. Russell Street),
LONDON, E.C.

Prescribed by Medical Men for
30 years,
and proved itself efficient in
Dyspepsia, Infantile Diarrhœa, Acute Indigestion, Morning Sickness,
Impaired Nutrition,
General Debility, Loss of Appetite, Constipation, Marasmus,
Flatulent Dyspepsia,
and other diseases of the digestive function.

"We can confidently recommend it."—(B.M.J.)

Supplied in ½oz., 1oz., 4oz., and 8oz. bottles.

JOHN MORGAN RICHARDS & SONS, Ltd.,
46 HOLBORN VIADUCT, LONDON, E.C.

THE LANCET.—"From clinical results published on the Continent, this Wine would appear to be of distinct value in CHLOROSIS and ANÆMIA. Its value in this connection depends most probably on the assimilable nature of the two medicinal constituents, the presence of which our analysis has confirmed."

Serravallo's Tonic

[Bark and Iron Wine.]

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXVI. WEDNESDAY, FEB. 19, 1908. No. 8.

NOTES AND COMMENTS.

Honour to whom Honour is Due.

OUR younger but more bulky contemporary, the *British Medical Journal*, publishes this week a disclaimer, in which it renounces the attribution to itself of our suggestion that the Government would make a good investment by setting aside funds to find a cure for, or method of prevention of, influenza. Our proposal was noticed at the time by several papers, the *World* and the *Daily Chronicle* among others, but the writers in these journals spoke of the question as having been raised by the *British Medical Journal*, and not by ourselves. As our object is to benefit the public through the medical profession, we should have been content to allow the *kudos* attaching to the idea to have rested with our contemporary, if it had not magnanimously refused the credit. The self-denying ordinance which it has imposed on itself by its disclaimer, however, is somewhat discounted in generosity by the fact that it says: "We have no wish to steal out contemporary's thunder, and therefore we hope it (THE MEDICAL PRESS AND CIRCULAR) may be duly credited with the proposal, as to which we do not think it necessary to express an opinion." We cannot but think this a little unkind. Is it "by such enlightened means that the bubbling passions of our contemporary find vent," we wonder? Is it, in fact, chagrin at having been forestalled in this Titanic conception? If the article in question be indeed a mere outpouring of jealousy we will try to be as philosophical as possible in bearing our blushing honours, and as the *British Medical Journal* expresses a desire to "render to the Cæsar of Henrietta Street that which belongs to him," we, for our own part, hasten to assure it that we will even be equally punctilious towards the deity of Catherine Street, not even laying claim to the encomiums it published of the methods of the "Horspool Natural Voice Academy (Limited)," which was so mercilessly shown up in the Courts last week.

Children's Bill.

THE Children's Bill introduced last week by the Under-Secretary of the Home Office is welcomed on every side, a fact which shows how rapidly we have travelled in the last few decades on the path of humanity and reason. Duty to the child was regarded in a very different light in the middle of the last century to that in which we now look at it, and though the newer ideas run at times into certain fond foolishnesses, they advance as a whole in the right direction. Still this country is very far behind some of the Colonies, notably Australia and New Zealand, and still further behind Japan, in recognising the advantage to the State of the proper nurture and upbringing of the young, and the Children's Bill in which we are priding ourselves would look to those countries about as tardy an act of wisdom as, say, compulsory elementary education in another country would to us. The chief complaint that can be lodged against the Bill is that it does not go far enough, especially in leaving the single baby-farmer immune from inspection. That question is to be probed by a Select Committee in the course of the session, but the vast magnitude of the evil is well-known to medical men who practice in poor neighbourhoods, and the objections to inspection can easily be overcome by discriminating administration.

Juvenile Smoking.

FOR our own part we regret that the Government have been captured by the "juvenile smoking" enthusiasts to the extent of making smoking by lads under sixteen a crime. Nobody supports juvenile smoking, just as nobody supports throwing stones at cats or "hanging on behind" vehicles, but it is plain to every man of sense that these childish tricks will not be put away till manhood is reached, and that in the meantime such actions may be foolish, but they are not criminal. We know of no evidence that smoking as a habit is at all frequent in boys under sixteen, although sporadic cases have been reported from time to time, but the youngster in the street who can secure a "fag" would be more or less than human if he denied himself the pleasure of puffing the last few whiffs out of it, and there is certainly no scientific basis for the idea that half-a-dozen puffs a week made a jot of difference to the health of any child in the world. From the speeches and writings of the anti-tobacconists, one would be led to believe that all the physical degeneration which we hear about, but which does not exist, is due to smoking in children, and we have seen it gravely stated that the decay of teeth, which, alas! is so prevalent, is due to the "habit," the supporters of the theory disregarding the fact that in respect to caries there is little or nothing to choose between girls who do not smoke and boys who (occasionally) do. The pity of it all is, that although the Government Bill is directed largely against making children into criminals, by providing special courts, and so on, the measure actually manufactures a crime by fining lads who have been once warned. We hope this objectionable and dangerous feature will be removed in Committee.

Anti-Crocodile Alliance.

IN these days of anti-rat campaigns and mosquito-destroying brigades, it is but natural that Professor Koch, having fastened on the crocodile as the alternative host of the sleeping-sickness trypanosome, should suggest an anti-crocodile alliance. This association he wishes to be of an international character, the English allying themselves with their Teutonic cousins in sworn hostility to the leviathan. As the Germans are particularly chary of entering into any bonds, political or fiscal, with us, this opportunity may be a favourable one for breaking the ice, and if taken at the flood may sweep away all misunderstandings and render extended Naval Programmes as obsolete as the torpedo-gunboat. The cosmopolitan or humanising influence of medical science could scarcely receive a more splendid *cachet* than that of removing the last bone of contention which occidental civilisation has to growl over. But would it not be well, before exchanging *pourparlers* on this alliance, to make quite sure that the crocodile is the faulty factor? It would be a thousand pities if, after equipping a fleet of *Dreadnoughts* or *Vaterlands* to patrol the rivers and lakes of Uganda, it were found that they were bombarding the wrong foe, as there would be no little danger of the milk of the holy alliance being turned to gall in consequence. We hesitate to think what effect it might have had on the peace of the world if Anglo-German amity had hinged on the therapeutic success of tuberculin when it was first introduced, or on the views taken by pathologists in the two countries on the identity of human and bovine tuberculosis.

A Criminal Libel.

A painful case of criminal libel on a medical man was tried at the Leicestershire Assizes last week, the defendant, a lady whom it is charitable to regard as being mentally unhinged, pleading guilty immediately. Dr. W. R. Tuckett, the medical man who was libelled, wisely placed his case in the hands of the Medical Defence Union, and as the libels were of a very offensive nature, and the lady expressed her determination to continue with them, there was no alternative but to prosecute her. The Medical Defence Union is not very popular with the blackmailing and welshing gentry who prey on medical men, and no doubt it has had some hard things said about it in its time by some of these disappointed ruffians, but we should be surprised if it was ever before informed, as it was by the defendant in this case, that it is "nothing but a powerful association for the protection of blunderers and criminals." Coming as it did, and from the source it did, we fancy this is indeed praise from Sir Hubert Stanley, and the General Secretary may plume himself on the reputation his Union possesses when it receives unsolicited testimonials of this kind from the publishers of criminal libels who find themselves in his toils.

Research Defence Society.

We hope that the newly-formed Research Defence Society will take every means to make its constitution and objects familiar to medical men, for such a body has long been needed. Scientific workers have for far too long taken the assaults made upon them "lying down," and the immunity which has attended the defaming of physiologists and pathologists—except in one memorable instance—has tempted mud-slingers to more and more daring efforts. With six or eight anti-vivisection societies spreading the tentacles of their organisations over the land, it is not astonishing that a good many recruits are gained to the cause, as their slanderous and unworthy statements are quite uncontradicted. Many people are hungering for instruction in the truth about scientific research, and it is only right and fair that it should be placed before them. When, as occasionally happens, a scientific man tackles anti-vivisectionists at one of their meetings, no more useful discussion takes place than if a member of the Cabinet were to try to argue the question of women's right to vote in a meeting of Suffragettes. What is really needed is instruction, not controversy; and if the Research Defence Society can manage to provide this, it will do a great and beneficent work.

LEADING ARTICLES.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND HOSPITAL APPOINTMENTS.

For many years past the attention of the medical profession has been drawn from time to time to the restrictions as to professional qualifications imposed in many hospital appointments. As a matter of fact, one of the higher English qualifications is requisite to the holding of nearly all the important London staff appointments, and of a considerable proportion of those in the country. This state of things creates a virtual monopoly in favour of certain examinations of certain Corporations and of the holders of certain privileged qualifications. It needs little argument to show the undesirablity of such an arrangement from the point of view of the hospitals, the medical profession, or the public. One of the first incentives to good work is freedom of competition and the possibility of rising to better things. The Fellows and Members of the Royal College of Surgeons, however, apparently do not seek to remove any restrictions that may have the effect of throwing open to competition hospital appointments, of which Fellows of their own College now enjoy the monopoly. They have requested their Council to use their moral influence with hospital authorities to recognise members of the College as having equal rights with Provincial, Scotch and Irish graduates to become candidates for hospital appointments. That is to say, the Member of a College is in future to rank with the graduate of a Scottish or Irish University. No English Universities are mentioned, so that we presume the Member of the Royal College of Surgeons of England, although he feels himself on an equal footing with the Scotch or Irish graduate, at the same time tacity admits his inferiority to the graduate of London. The nicety of these distinctions, we are bound to confess, rests on grounds too subtle for our comprehension. The Council of the College have determined to issue a memorandum on the subject prepared by a special committee, to hospitals in England and Wales. It is to be hoped that the grounds upon which they have undertaken to use their moral influence will be made abundantly clear to all concerned. Reduced to a plain proposition, the Council of the Royal College of Surgeons is asking the various hospital authorities throughout England and Wales to give their diplomates the advantages which attach to the graduate of a University. The depths of this plan will be disclosed to the hospitals only when they learn that it is not intended to provide the London student with a University degree. Had the College been in touch with the trend of modern thought, it would have sought to bring into open competition those hospital posts which have for so long been monopolised by their own Fellows. Why should not Fellows of Scotch and Irish Colleges have an equal chance of securing hospital appointments in all parts of the Kingdom? The advancement of medical skill and education is clearly a matter that concerns the community at large, and not the selfish interests of any single College and its Fellows. The report from the Committee of the Council appointed to deal with the matter referred to the returns from the medical examinations of the Royal Navy, the Royal Army Medical Corps, and the Indian Medical Service for the past five years. They showed that the candidates holding the diploma of M.R.C.S.Eng. and L.R.C.P.Lond. had obtained a very high percentages of places, and that in twenty-seven examinations they had gained the first place on eighteen occasions. We cannot admit that excellence of examination standards furnishes all-sufficing proof of a man's fitness for hospital work. Nor, on the other hand, do we for a moment question the soundness of the education tests exacted by the English conjoint examiners. It is another and a very different matter, however, when we are asked to say that holders of the qualifications referred to are to be placed forthwith on a footing with Scotch and Irish medical graduates, in order that the English College may retain its monopoly. If the members are of such importance, how is it that the Council of the College refuses them a voice in the government of the College? If the English conjoint qualification is to be henceforth considered morally as an equivalent to a Scotch or Irish degree why do not the Colleges face the situation squarely and unite with a third great Corporation and grant a London University degree on terms of a reasonable standard? Unconsciously this step of the College of Surgeons in addressing the hospitals of England and Wales has promoted a strong argument in favour of the one portal system. Well may the hospital authorities ask, What is the use of taking a university degree when a college diploma will do as well? If these things be equal why should there be any distinctions between them? If the lawyers be content with one portal to qualification, why should the medical profession want twenty? Some day medical men generally will probably realise that their interests will be advanced and consolidated by the fusion of a number of competing corporations into one representatively-governed qualifying body.

CURRENT TOPICS.

The Parasites of Medical Science.

THE root principles that govern mankind appear to be much the same under all suns. In the case of legitimate medicine and quackery the two seem bound to go hand in hand until the age of perfect wisdom dawns upon the earth. As things go, whenever the virtues of a new drug are proclaimed amongst medical men, it is a foregone conclusion that within a few weeks it will be advertised to the public under some fancy name with claims to curative powers that would simply make its original investigators and discoverers stand aghast. Yet a tolerant Government looks on and permits the community to be plundered by wares that are sold under obviously false pretences. In other countries (such as the Cape) the plague is rampant. Curiously, in Japan it flourishes as the green bay tree, and is carried on by a vast organisation of pedlars. We say "curiously," because the facile Japanese have rapidly seized upon the best of our western medical knowledge and applied it thoroughly and scientifically in their everyday life. May we presume that it is the difficulty of interfering with vested interests that leads them to tolerate the flood of quack medicine with which the land of the Rising Sun is flooded? We learn from the Asiatic Society of Japan's journal that the quacks employ such euphonious names as "life-supporting powders," "touch-the-spot pastilles," "spirit-cheering pills," and one supremely comprehensive nostrum is called "best-everything powders."

An Open-air Scheme for Consumptives.

A GOOD beginning is being made in Buckinghamshire in the treatment of convalescents from consumption. As medical men know there is a critical stage after the disappearance of the signs and symptoms of active tuberculosis, when the sufferer if often compelled to return prematurely to the undesirable environment of home and workshop. Could he be safely tided over that period of convalescence his chances of permanent benefit would be greatly multiplied. Thanks to the co-operation of Lord Carrington, twenty-eight acres of land have been acquired at High Wycombe for the class of patients in question. The scheme provides for their employment in the open-air, and is to be started forthwith by the breaking up of the land. The present intention is to commence with the growing of vegetables, after which more extended market-gardening operations are to follow. It is also proposed to undertake the rearing and fattening of pigs, and, later, to begin experiments in fruit culture. A partially self-supporting scheme of this kind appears to be formed on a sound basis, and furnishes the supplementary open-air course that is needed after sanatorium treatment. The actual cost will not be great, especially when compared with the excessive outlay upon palatial sanatoria that has been witnessed in recent years.

Rules and the Coroner.

THE Westminster Coroner, Mr. John Troutbeck, appears to have somewhat peculiar views as to the rights of medical witnesses. His theory, judging from a report of a recent inquest, is that a medical practitioner should attend as a witness without fee if his evidence be required in self-defence. Mr. Troutbeck, however, has, not unnaturally, lost the confidence of the profession of his district, where the medical practitioners have been for a long time past deprived of a source of legitimate income by the employment of a so-called "expert" pathologist in the Coroner's Court. In the case under notice, a medical man attended an epileptic for burns sustained while in a fit. The patient was removed to the Wandsworth Infirmary, where he died after a succession of fits. The medical evidence gave the cause of death as heart failure while suffering from epilepsy, accelerated by burns. The medical man who put in evidence was told by the Coroner's officer that there was a complaint against him, but he refused to attend the inquest unless summoned. The Coroner thereupon said (so it is reported in the *Times*) that he was not going to pay a gentleman a guinea for explaining an accusation; it was not right to put that amount on the rates, especially as there was no doubt as to the cause of the death. The jury took the Coroner seriously, and added to their verdict an opinion that the medical man did not exercise proper medical skill when first called in, and was deserving of censure. Mr. Troutbeck pointed out that the treatment had not been discussed by technical witnesses, and only a lay opinion had been given. We are glad to believe that very few Coroners would adopt so extraordinary an attitude with regard to the summoning of medical witnesses. Lest the absence of Dr. Freyberger's name from this particular inquest should arouse any medical anxiety on the part of local practitioners, it may be added that a few days later he gave evidence in Mr. Troutbeck's Court as to the death of a professor of physical training due to heart failure following influenza. It is to be presumed that Dr. Freyberger's evidence cost the rates at least two guineas, and it is not easy to say why the nearest practitioner would not have been equal to the occasion and given satisfactory evidence as to the cause of death, even under the exacting jurisdiction of the Westminster Coroner.

Fisherfolk and Influenza.

LAST week it was announced that a famine of fish had followed an outbreak of influenza among the fisherfolk of Grimsby. To the man in the street this looks like a reversal of the ordinary laws of Nature. Surely, of all men, he would argue, fisherfolk, who live so much in the open, should be free from rheums and infective catarrhs. So they should, in theory, but, as a matter of fact, a large portion of their lives is spent in miserably small, overcrowded, and ill-ventilated dwellings. Taken as a whole, it may be doubted if there is any single class of society worse housed than the fisherfolk of the United Kingdom. Then when they go to sea, their cabins are on the same cramped and ill-ventilated scale. It is clearly of little use for a man to spend his time at sea in wholesome air when a great portion of it is passed in a noisome atmosphere. Even then, such is the hardihood of the seafaring constitution, he may go on well enough for many a year. The risks of his environment are brought into relief only when his cribbed quarters are invaded by some acute infection. Then the close contact of crowded cottages and cabins acts like a spark in gunpowder, and the results are such as have marked the outbreak of influenza at Grimsby.

The Royal College of Surgeons of England.

AT an ordinary meeting of the Council held on the 13th inst., Mr. Henry Morris presiding, the Council appointed Mr. Arthur Keith, F.R.C.S., to the office of Conservator of the Museum, rendered vacant by the death of Professor Charles Stewart. With reference to the resolution carried at the annual meeting of Fellows and members asking the Council to use their moral influence with hospital authorities to recognise members of the College as having equal rights with Provincial, Scotch and Irish graduates to become candidates for hospital appointments, the Council decided to circulate a memorandum on the subject, prepared by a committee of the Council, to hospitals in England and Wales. The report from the committee referred to the returns as to the examinations from the Medical Department of the Royal Navy, the Royal Army Medical Corps, and the Indian Medical Service during the last five years, and showed that candidates holding the diplomas of M.R.C.S.Eng. and L.R.C.P.Lond. had obtained a very high percentage of passes, and that in twenty-seven examinations they had gained the first place on eighteen occasions. A form of circular to the Fellows and members of the College asking their opinion as to whether or not women should be admitted to examination for the diplomas of the College was adopted, and the secretary was instructed to issue the circular to all Fellows whose addresses are registered at the College, and to all members whose addresses are entered upon the "Medical Register" of the United Kingdom or elsewhere. In the meantime the Council decided to inform the Royal College of Physicians that, pending the result of this inquiry, they did not propose to take any further steps with regard to the petition from the London School of Medicine for Women. Mr. W. Watson Cheyne, C.B., F.R.S., was appointed Bradshaw Lecturer for the ensuing collegiate year, and Mr. J. Ward Cousins was re-elected the representative of the College upon the Central Midwives Board for a further period of one year. Upon the suggestion of the President a small committee was appointed with the object of keeping the Council informed as to what is being done from time to time regarding the medical inspection of school children and the arrangements for teaching elementary hygiene in training colleges and schools.

The Discovery of Chloroform.

IT is not wonderful that in many instances the claims of men to the credit of an invention usually associated with their names are questioned. In many cases, indeed, the ascription is due to an error, the propagandist being mistaken for the discoverer. In other cases, he who has contributed some important development is credited with the invention of the thing he has developed. Thus, a large proportion of the population of the Kingdom is under the impression that Stephenson invented the steam engine, whereas he applied it to railway locomotion. In other fields, the rights of Harvey to be called the discoverer of the circulation have been questioned in favour of Servetus and others, who certainly taught very much the same truths as Harvey, though they may not have grasped them in their entirety. The title of Garcia to the laryngoscope is also open to question, though whether he had priority or not, the discovery was with him an original one. The battle over the contending claims to the discovery of the use of ether as an anæsthetic is of long standing and severe. It is no wonder, therefore, that the right of Simpson to the title "discoverer of chloroform" is also questioned. An interesting correspondence took place last month in the columns of *The Pharmaceutical Journal* on the subject, and there seems to be little doubt that the discovery was certainly not due to Simpson alone, but was due to the co-operation of a group, including Matthews Duncan, Waldie of Liverpool, and Keith, as well as Simpson, and that Duncan was probably the first to try the effects of the drug on himself. It is true, too, that the effects of the drug on animals had been established five or six years earlier by Glover. In spite of these facts, it would be a narrow mind which would make little of Simpson's work, since it was he who first appreciated the greatness of the discovery, and devoted himself, in the teeth of bitter opposition, to securing for chloroform its proper place in the world of surgery.

Deaths by Poison.

THE Registrar-General's returns of the deaths by poisoning in 1906 contain some points of interest. Among the poisons as causes of accidental death, opium and its derivatives take first place with 73 deaths out of 245; carbolic acid caused 21 deaths, hydrochloric acid 17, lead 14, ammonia 13, and oxalic acid 11. Phosphorus matches caused six deaths. Of the total number of accidental deaths by poisons, 144 were of males and 101 of females. Males had a similar preponderance among the suicides by poisoning—331 out of a total of 534. As usual, carbolic acid is the favourite drug for suicide, being responsible for 120 deaths. Oxalic acid caused 98 deaths, hydrochloric acid 86, opium and its derivatives 52, potassium cyanide 35, hydrocyanic acid 28. It is obvious that it is rather facility in procuring than any question of choice which determines the poison for suicide. The returns of deaths under anæsthetics are specially interesting; 183 deaths were recorded, the agents employed and the deaths credited to them being: A.C.E. mixture, 3; chloroform, 107; chloroform and ether, 8; ether, 8; ethyl chloride, 8; nitrous oxide, 3; not stated, 46. The preponderance of chloroform in the fatality list is as usual in these returns. Deducting the 46 cases in which the agent was not recorded, it is to be seen that chloroform was employed in 118 of 137 fatal cases. Ether alone was employed in 8, and in conjunction with chloroform in 11 others. In spite of such returns, which year after year point to the dangers of chloroform, it is still a favourite anæsthetic throughout England.

PERSONAL.

LORD LISTER has been awarded the Mary Kingsley Medal by the Liverpool School of Tropical Medicine.

DR. J. O. AFFLECK is to be the recipient of an honorary LL.D. at Edinburgh University.

MAJOR J. HARPER, M.D., will succeed Col. V. Matthews in the command of the London companies of the Royal Army Medical Corps early in April.

DR. P. W. MACDONALD will preside at the next quarterly meeting of the Medico-Psychological Society to be held to-morrow at Warwick County Asylum.

THE University of Edinburgh propose to confer the honorary degree of Doctor of Laws upon the Lord Mayor of Liverpool, Dr. Caton.

MR. ARTHUR KEITH, F.R.C.S., has been appointed Conservator of the Museum of the Royal College of Surgeons of England, rendered vacant by the death of Professor Charles Stewart.

MR. BERNARD H. WEDD, M.B., M.R.C.P., D.P.H., has been appointed Bacteriologist to the Royal London Ophthalmic Hospital, E.C. Mr. A. N. Leeming succeeds Mr. Wedd at Guy's.

DR. R. C. JEWESBURY, M.R.C.P., of Charing Cross Hospital, has been appointed Physician with Charge of Out-Patients at the Victoria Hospital for Children, Chelsea.

DR. J. A. W. PEREIRA, of Exeter, has been presented by the police force of that town with a portrait of himself as a mark of their appreciation of his services.

DR. J. KINGSTON FOWLER will take the chair at the 135th anniversary dinner of the Medical Society of London on March 11th at 7.30. The dinner will be held at the Whitehall Rooms.

COLONEL DOUGLAS WARDROP has been appointed Commandant and Director of Studies at the Royal Army Medical College, *vice* Lieutenant-Colonel H. E. R. James, R.A.M.C.

THE Freedom of the City of London is to be conferred on Miss Florence Nightingale. A special subcommittee of the Common Council has been appointed to make the necessary arrangements.

DR. R. OWEN MORRIS has been appointed Medical Officer of the Council Schools at Birkenhead, and Dr. R. S. Marsden, Medical Officer of Health to the borough, Superintendent Medical Officer of Schools.

DR. ALEXANDER BRUCE and Mr. F. M. Caird have been re-appointed for five years to their present posts, those of Pathologist and Resident Physician and Surgeon respectively, at the Edinburgh Royal Infirmary.

DR. DAVID FERRIER, M.D., F.R.C.P., has resigned his appointment of Physician to King's College Hospital after many years' service to that institution. He will, however, retain the Professorship of Neuro-Pathology in the King's College Hospital Medical School.

THE Assistant Physiciancy at the Royal Free Hospital has been filled by the appointment of Dr. W. P. S. Branson, M.D., M.R.C.P., of St. Bartholomew's Hospital, where he holds the post of Junior Curator of the museum.

THE Middlemore Prize for Ophthalmology has been awarded by the Council of the British Medical Association to Mr. Simeon Snell, F.R.C.S.Edin. The prize, £50 and an illuminated address, will be presented to him at the next annual meeting.

THE sum of £1,000 has been collected among the patients and friends of the late Dr. W. S. Playfair, and is to be presented to King's College Hospital with a view to erecting a memorial to him at the institution with which he was so long associated. It has been decided by the Removal Fund Committee to devote this money to the building and equipment of an appropriate department of the new hospital shortly to be erected at Denmark Hill, this department to be named after him, and to bear an inscription recording his thirty-five years' work at King's College Hospital.

A CLINICAL LECTURE

ON

THE DIAGNOSIS OF INJURIES ABOUT THE SHOULDER. (a)

By J. DUNDON, M.B., F.R.C.S.Eng. and Irel.,

Surgeon, Mercy Hospital, Cork; Senior Assistant Surgeon, North City and County Infirmary, Cork.

GENTLEMEN,—The subject which I wish to bring under your notice to-day is one of considerable importance, embracing, as it does, injuries of comparative frequent occurrence that are attended with serious and disastrous consequences if not properly diagnosed and treated. Fractures and dislocations seem not to have that interest for students that we would expect from their importance and frequent occurrence. Students seem to be more interested in the daring exploits of abdominal surgery rather than in the full and accurate study of the more common ailments of the community. This, to my mind, is a very serious mistake on their part, and I have not the least doubt that, from different causes, not more than 5 to 10 per cent. of those now reading surgery will ever get an opportunity of putting into practice that knowledge of abdominal surgery which they are now so intent on, whilst 90 to 95 per cent. will have to treat perhaps frequently injuries that include fractures and dislocations. The treatment, if successful, may in any individual case have a very important influence in your chance of success in practice, but if results are bad, serious, if not fatal, impediments to your advance will arise, apart altogether from the wrecking of the usefulness and earning capacity of probably a bread-winner. Advances in treatment in this particular part of surgery have taken place, but as they require great operative dexterity and scrupulous conformity with rigid asepsis, are only to be carried out by an experienced surgeon who has all the requisite skilled help. They are not for the general practitioner. The latter has, in the great majority of cases, to depend on less heroic and simpler forms of non-operative treatment. The best results from treatment will only arise when you can be absolutely sure of your diagnosis. Precision in diagnosis is often rendered difficult by swelling, slight or doubtful physical symptoms, and frequently by the fact that more than one injury may be present. Accurate diagnosis may be impossible when the fragment broken off is small or fracture impacted. Inaccuracy of diagnosis must be attended by unskilful treatment, and this in turn by results prejudicial, temporary or permanent, to the restoration of the normal functions in a part. This failure to restore a limb to its normal condition may be a matter of grave import to the patient and those dependent on him, and I would like to impress on you that a painstaking and conscientious surgeon who labours to restore an injured limb to its proper functions is as deserving of our praise as the laparotomist whom we are accustomed to loudly acclaim. You may be assisted in some cases by the use of the X-rays or fluorescent screen, and it is well to make use of these in all doubtful cases when they are available. But you should accustom yourself to make your diagnosis without their use, as they may not be available. Another form of help that you will find of considerable advantage in obscure cases will be the use of an anæsthetic to enable you to make a thorough and exhaustive examination, especially in nervous patients.

Some injuries are obvious, and by even superficial examination, as well as on comparison with opposite limb present little or no difficulty. Do not be satisfied with the recognition of an obvious injury—make it a practice to make your examination thorough, so as to obviate the annoying mistake of overlooking a complication, or perhaps a second injury. Some injuries are obscure, and it is only by the most careful and methodical examination that a correct diagnosis can be made. Such a method of examination, with appropriate remarks, I intend to bring before your notice to-day.

Full history of case is most important, as it gives us information of previous injuries to the part, probably fractures or dislocation may have occurred formerly, leaving symptoms that may obscure our present inquiry.

Nature of the violence, whether direct or indirect, and the direction of application, have often an important bearing on the diagnosis of injuries round the shoulder-joint. Dislocations occur more frequently with indirect, and fractures with direct violence.

Time of occurrence, whether recent or long duration, as in the latter case atrophy of muscles from disuse or paralysis may simulate superficially the deformity of dislocation. This is specially marked in atrophy of the deltoid. Next inquire from patient what it is he complains of. The answer to this may help you as fixing the seat of localised pain.

Now remove all clothes from the upper part of body, fully exposing both sides. Place patient on a chair, and exposed to a good light. Then, by means of inspection, note the *attitude* of patient, the latter assuming an attitude that is frequently characteristic, especially in non-impacted fractures. Observe the curves of both clavicles, the prominence of acromion processes, the contour of shoulder over deltoid, the length of anterior boundary of axilla (lengthened in practically all dislocations of humerus), the direction of the axis of humerus, and compare the groove between deltoid and pectoralis major (usually obliterated in dislocations inwards).

Next: Determine the amount of active and passive movement, and if movement is associated with pain. If passive movement, in contrast to active movement, is considerable, but attended with pain, probably a non-impacted fracture is present.

Next: Measure from the following points, and compare with the sound side:—

Clavicle from acromion process to sternum: if shortening, probably a fracture; if no alteration, a dislocation can be excluded.

Acromion to elbow: shortening, probably fracture of shaft or upper end of humerus, with rarer forms of dislocation—*e.g.*, sub-spinous and supra-coracoid.

If lengthened—sub-glenoid dislocation: fracture of glenoid cavity and possibly fracture of the outer part of acromion process.

Next measure width around axilla; if increased, probably inward dislocation of humerus.

Measure from greater tuberosity to mid-line: if lengthened, fracture of greater tuberosity; if shortened, dislocation of head inwards.

Measure distance of coracoid below outer third of clavicle: if lengthened, probably fracture of coracoid or fracture of glenoid cavity, with coracoid process.

Next you employ *palpation*. Standing behind patient, run your finger along the clavicle from the supra-sternal notch outwards on both sides. As the clavicle is subcutaneous in its entire course, you note any alteration of curves or anterior surface. A fracture at middle third is quite obvious, and is attended with the usual symptoms. A fracture at inner extremity is rare, and must be distinguished from dislocation of clavicle by no alteration in length of latter and absence of crepitus, and from separation of epiphyses, by age of patient and nature of crepitus. Doubtful cases presenting little or no deformity are inter-ligamentous fractures (between coracoid and trapezoid ligaments), and greenstick fractures of children. They may be suspected, and a guarded diagnosis given if you find slight irregularity, with localised pain and tenderness. In greenstick fractures you may also be able to detect alteration in the anterior curve, and some irregularity on carefully palpating posterior surface. Further out, beyond the clavicle, you feel the acromion process, where you may get fracture, dislocation and separation of epiphyses. Irregularity, mobility, and crepitus, with slight flattening of deltoid, would denote fracture. Always compare acromion process carefully with the one of the opposite side, as there is frequently a gap or sulcus in the situation of the joint which simulates a dislocation, but is usually symmetrical. Dislocation of acromion is usually below and rarely above clavicle. Careful examination and comparison with opposite side will enable you to diagnose it.

(a) Lecture delivered at the North Infirmary, Cork.

Next examine scapula by running your fingers along the spine and vertebral border of both sides. Grasping the inferior angle of scapula and moving arm will enable you to detect fracture of body, which always results from severe and direct violence. Below the outer third of clavicle will be found the coracoid, fracture of which is due to direct and severe violence, and is usually accompanied with extensive extravasation.

Next examine the region of the shoulder-joint proper. Here you may have fractures, dislocations, or both, as well as contusions of muscles and sprains of joint, and owing to the depth of part as well as the extensive extravasation that may be present, great difficulty may be experienced in making a diagnosis. An accurate diagnosis is absolutely essential, otherwise serious impairment of function may result. It is in these cases that X-rays and an anæsthetic are of great importance as an aid to diagnosis.

Always examine the uninjured shoulder first, as it gives you a definite idea of the normal condition, and will enable you to better appreciate and value symptoms on the injured side. If there be great swelling of parts, it is probably due to great violence, and it is particularly in these cases you may expect several injuries, and it is advisable, in the absence of X-rays, to put the patient under an anæsthetic which may be utilised if the injury turns out to be a dislocation.

Now, having taken note of the prominence of acromion process, contour over deltoid, length of anterior border of axilla, and direction of axis of shaft of humerus, try to locate head of humerus. Normally, this is immediately *below* and *projects slightly beyond acromion process*, and if by pressing in our fingers immediately below the acromion we find a depression as compared with sound side, we know we have to deal with a dislocation of humerus. This method is simple, quick, absolutely reliable, and can be corroborated by other methods, such as—

Duga's sign—that the patient cannot place the fingers of the injured limb on the sound shoulder, nor allow them to be placed there by the examiner while at the same time the elbow touches the side.

Calloway's sign—that the vertical measurement round the axilla and through the acromion process is greater than the sound side by one to two inches.

Hamilton's sign—when a straight piece of board, such as a splint, is placed with one end resting on the external condyle of the humerus, and the other on the prominence of the shoulder, in a healthy arm the upper end should be separated from the acromion process about one inch, but in dislocation it rests against the process.

Now, having decided that we have to deal with a dislocation, we ask ourselves the question: Are there any injuries like a dislocation? and the answer is, as you know, that fracture of acromion process and fracture of neck of scapula present some symptoms such as flattening of shoulder and lengthening of arm somewhat similar to dislocation; but in these cases there is always well-marked resistance below the acromion; never the marked depression noticed in dislocation. In these two injuries also, reduction can be readily produced with possibly signs of crepitus, but the deformity immediately recurs on releasing the pressure. By feeling also through the axilla, especially in a thin subject, or in one in whom there is little extravasation, the head of humerus may be found in glenoid cavity, or in an abnormal position.

Next, if there is a dislocation, how do we determine the position of head, and so the variety? We do this by noting the direction of the axis of humerus; the more abducted the shaft, the lower the head. If slight abduction, probably sub-coracoid, to confirm which we examine the groove between pectoralis major and deltoid, and we find it obliterated, and the position of coracoid obscured. If marked abduction, probably sub-glenoid, which we confirm by noticing the bulging of floor of axilla by lengthening of arm, and possibly pressure on vessels and nerves. If the axis is directed backwards, we have the rarer form of sub-clavicular dislocation, with other obvious symptoms. If axis be directed forwards, we have the sub-spinous variety. The supra-coracoid and luxatio erecta need not detain us, as they are very rare.

The next question we have to answer is, what complications may arise with dislocation? We know that compression of the circumflex or musculo-spiral nerves are the most usual complications of fractures. We look out for symptoms of these.

Remember that usually in dislocation the arm is away from the side, and that in fracture it usually lies helpless by the side.

Next we investigate to see if we have to deal with a fracture. The usual signs of a fracture are, as you know, bony crepitus and præternatural mobility between two joints, and some modification of length of bone, usually shortening, as well as loss of function. Unfortunately, these are not always present in cases of fracture at the shoulder-joint, as one may have an impacted fracture without crepitus, præternatural mobility, or any appreciable alteration in the length of limb. Still, measurements of the length of the limb are of great importance, as, if we can exclude dislocation (and this we can do very readily by noticing the presence or absence of head under acromion process), any shortening of the limb points to fracture of the shaft or upper end. Now the two methods we adopt to ascertain the presence or absence of fracture are as follows:—First, we measure from the acromion process to the internal or external condyle of each side. This gives us alteration in length, if any be present, and we get:—

(1) No alteration in length: possibly no fracture, though fracture of head of humerus and fracture of greater tuberosity may be present without alteration in length.

(2) Shortening: possibly fractures.

(3) Slight lengthening: fracture of acromion; fracture of glenoid cavity.

We note the amount of these, and then measure from outer surface of greater tuberosity to the mid-line. This gives us:—

(1) No change: possibly fractures at neck it accompanied by shortening of length of axis of limb.

(2) Shortening: inward dislocations.

(3) Increase: fracture of greater tuberosity.

Next we examine for crepitus, and it is well to do this in a methodical and routine manner. Place hand on outer surface of deltoid, grasp limb at elbow, and rotate shaft in and out. Note whether—

(1) Head moves with shaft, or

(2) Head does not move with shaft.

Having noted that head moves with shaft, examine carefully for crepitus. The following deductions may be made:—

If no crepitus, no complete fracture is present, but there may be an impacted intra- or extra-capsular fracture.

In the latter case you would expect that the injury was applied directly to the part, was the result of comparatively great violence, and that the length of limb would be variably altered from slight or scarcely appreciable shortening in intra-capsular to a shortening of ½ in. to ¾ in. in impacted extra-capsular. A far more important point than the shortening, which may be very slight and difficult to accurately estimate, is a close and attentive examination of the outline of the head of humerus, as felt in the axilla and at anterior and posterior border of the deltoid. Any irregularity of head of humerus favours the diagnosis of impacted fracture.

Next, if head moves with shaft and distinct crepitus is felt, you have two classes:—

(*a*) Without lengthening of limb.

(*b*) With alteration of length of limb, and crepitus, movement of head with shaft, and lengthening of limb.

(*a*)—(1) Fracture of glenoid cavity; (2) fracture of anatomical neck of scapula.

(*b*) Fracture of neck of scapula, including separation of coracoid process.

In (1), the alteration in length is slight, if any; crepitus can be felt on moving head of humerus, and remember that it is not a common injury, and rarely occurs without dislocation. The same applies to (2). These injuries have been more frequently diagnosed only since the advent of the X-rays or screen, but are possible as the result of great violence. In (*b*) the injury is like a sub-glenoid dislocation. There is lengthening of limb, flattening over deltoid prominence of acromion process, but in moving limb crepitus is marked, especially by placing one hand over acromion process and then lifting up limb by grasping the elbow. The superficial resemblance to a dislocation is readily removed on elevation of limb, with the production of crepitus, but readily returns on relieving pressure.

In (*a*) we found crepitus without any alteration of length of limb, and head moves with shaft. This is also found in fracture of greater tuberosity. This fracture is the result of great direct violence, and in it we usually find increase in length of line from greater tuberosity to mid-line, and occasionally a groove or sulcus between shaft and greater tuberosity.

Now, supposing head does not move with shaft, and there is distinct crepitus, marked shortening and deformity, we may have one of several conditions:—

(1) Intra-capsular—non-impacted fracture.
(2) Extra-capsular—non-impacted fracture.
(3) Separation of upper epiphyses.
(4) Fracture and dislocation.

In these injuries we get well-marked symptoms of crepitus, shortening, varying from slight in intracapsular to great in separation of epiphyses and fracture and dislocation combined. We also get more or less characteristic deformities in extra-capsular non-impacted fracture and separation of epiphyses. In the former we get a condition which is superficially like a dislocation—that is, flattening and alteration of the contour of deltoid, but if we examine closely we shall find resistance immediately under the acromion process, showing head is in the glenoid cavity, and we note that the flattening does not begin at acromion, but at level of greater tuberosity. We also have to remember that in intra- and extra-capsular fracture the injury is generally due to direct violence, and that when non-impacted a careful examination through axilla gives great help. Even when non-impacted, the intra-capsular may not show marked signs of crepitus or shortening, and it is advisable not to be too persistent in our endeavours to elicit these points, or, if having once ascertained them, to avoid undue injury by frequent repetition. Separation of upper epiphyses will occur under 20 years, is somewhat similar to an extra-capsular fracture, and, like it, may be partially or wholly separated from the shaft. When completely separated from shaft, it presents a characteristic deformity, the upper end of shaft projecting at axilla in the form of a nipple-shaped projection (the conical end of the diaphyses). Separation of the epiphyses and extra-capsular fracture are very like inward dislocation, but a diagnosis can be made by noticing the head of humerus in the glenoid cavity immediately below the acromion process, flattening of deltoid and prominence of acromion will not be so marked, and a depression and want of resistance on pressure will be found immediately below greater tuberosity.

In these fractures there may be comparatively slight to extensive shortening, and the more marked the shortening the less doubt you will have as to the site or nature of the lesion. Slight or doubtful shortening occurring in intra-capsular fracture, impacted or non-impacted, marked shortening only in separation of epiphyses, extra-capsular, and fractures of shaft.

Having excluded intra-capsular and extra-capsular fractures, and separation of the epiphyses, and having noticed that head of humerus does not move with shaft, we ascertain if there is a fracture with dislocation. Now, in severe injuries, especially due to direct violence, it has been known for a long time that dislocations are often attended by fractures of some of the component parts of the joint. The exact nature of these injuries has been investigated by Robert Jones by means of X-rays, and he finds that the frequency of fracture with dislocation is more common than is usually supposed, that it is usually met with in middle-aged people as the result of great and direct violence, and that we may suspect the association of fracture and dislocation if there is a marked hæmorrhagic extravasation in the axilla, if pain be severe and mobility at shoulder more marked than in ordinary cases of dislocation. He finds that the order of frequency of fracture with dislocation is (1) fracture of surgical neck; (2) separation of greater tuberosity; (3) separation of anatomical neck with tuberosities; (4) neck of scapula with coracoid process; (5) lesser tuberosities; (6) fracture glenoid cavity; (7) fracture glenoid cavity and anatomical neck.

The most difficult cases you will have to deal with will be cases seen a few days after the injury has occurred with possibly great swelling of parts, cases in which the injury is the result of great violence, and where possibly you may have more than one lesion, or possibly some rare and unsuspected injury. In these cases you must be extremely careful in your diagnosis and guarded in your prognosis, and it behoves you to make use of all the help that physical science gives you, but remember that whilst using and trusting these methods of diagnosis that they are not infallible, are oftentimes not available, and that by a careful but methodical plan of investigation possibly, in the hands of experienced surgeons, equally good results may be obtained. Whether that is so or no, what I want to particularly impress on you is to educate yourselves so that you can in the great majority of cases make an accurate diagnosis, for without accuracy of diagnosis appropriate treatment can scarcely be applied with the anticipation of getting useful or satisfactory results.

In conclusion, I would strongly impress on you the following points: Make a thorough, and above all, a methodical examination. Do not be too ready to assume the presence of contusion of deltoid or sprain of shoulder-joint, if you have failed after a superficial and cursory examination to elicit marked symptoms. Remember that an impacted fracture of the neck in a very muscular patient may present very slight symptoms, and may be and often is overlooked in a hasty examination. Do not try to make a diagnosis on one symptom or on so-called pathognomonic sign (*e.g.*, Duga's Symptom for Dislocation). If a dislocation be present you can get other and more reliable symptoms if you persevere in your investigation. If you have any doubt, use an anæsthetic and the X-rays if available, but even the use of the X-rays ought not to make you lax in your thorough examination by inspection, mensuration, and palpation. If you remember that severe direct violence is likely to produce cases troublesome from a diagnostic point of view you will make your examination as full and as exhaustive as possible.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Dr. Vilmos Goldzieher, Professor of Ophthalmology at the University of Budapest. Subject: "The Treatment of Pannus following Trachoma by Inoculating the Eye with Gonorrhœal Pus."*

A PROVINCIAL sessional meeting of the Royal Sanitary Institute was held at the Exchange, Nottingham, on Saturday. Mr. H. D. Searles Wood (chairman of the Council of the Institute) presided over a large attendance. The subject under discussion was road requirements in their relation to the dust nuisance. The Mayor of Nottingham (Councillor J. T. Spalding) extended an official welcome to the members.

ORIGINAL PAPERS.

CONVALESCENCE AND ITS STAGES; AND SOME OF THE PHYSICAL AIDS AVAILABLE FOR THEM. (*a*)

By WILLIAM EWART, M.D.Cantab., F.R.C.P.,

Consulting Physician to St. George's Hospital; Senior Physician to the Belgrave Hospital for Children.

The greater or less rapidity of our cures is of some importance to all classes of patients, and not least to the breadwinners who are to be found in hospitals. For them it is vital not to be long detained from home and from work, though not less important not to be discharged in a state of unfinished recovery, or of imperfect convalescence. As a fact, there is seldom any stint, but sometimes an excess of liberality in the time allowance; and this reminds us that the precept "*Cito, tuto, et jucunde,*" should be applicable, not only to treating, but to convalescing our patients rapidly. The time question touches the economical interests of the charity and the health interests of the community. How to shorten the period of treatment is not before us to-day; but it may be worth considering whether a saving of the patients' time, and of the hospital "beds" might not be effected by additional attention to the management of convalescence. As the majority of convalescents are of the medical description, my remarks will apply largely, but by no means exclusively, to them.

A liberal diet is a first essential; and I need not dwell upon the obvious principle that true economy consists in "feeding up" our patients, if possible, during their illness, but at any rate during their convalescence. *The suitable medicinal management* of the cases is another subject not under our present consideration. It is to *the physical hygiene of convalescence* that I would turn your attention, with special regard to the mechanical assistance which can be provided for hospital patients, as well as for private patients, for the more rapid restoration of their muscular energy and tissue.

The stages of convalescence may be conveniently described as:—(1) The Bed Stage; (2) the Out-of-Bed Stage; and (3) the Out-of-Door Stage.

The third stage is that which eventually takes private patients away to distant climates for recuperation; and our hospital patients away to convalescent homes. I believe that it might sometimes be much less delayed if both previous stages could be more actively managed, and somewhat shortened.

I am of impression that an over anxiety for our patients is apt now and then to prolong the bed stage. Doubtless the management of wards is in a measure simplified by keeping some of the patients quietly in bed. And it cannot be gainsaid that, so long as a liberal diet is supplied, the principal purpose is being served, along lines of absolute safety. At the same time the main indication in convalescence is *the recovery of the tissues and of the functions by their graduated use*. Any unnecessary delay in this systematic re-education is wasteful, for unless we can exercise our bedridden convalescents in their beds it must be slow work for the muscular system and for the heart to regain weight and power in the absence of the natural stimulus of movement.

In surgical practice, it is now a recognised common-sense principle "to rest and protect the damaged part or limb, but to set the body free." In most medical cases we have to deal with two similar indications, which are not incompatible if we know how to combine them, viz.: (1) the improvement of the general and of the cardiac nutrition; and (2) the improvement of the local health and strength of the suffering or impaired peripheral mechanisms. Practical care devoted to these objects will be amply rewarded in the results.

The Bed Stage.

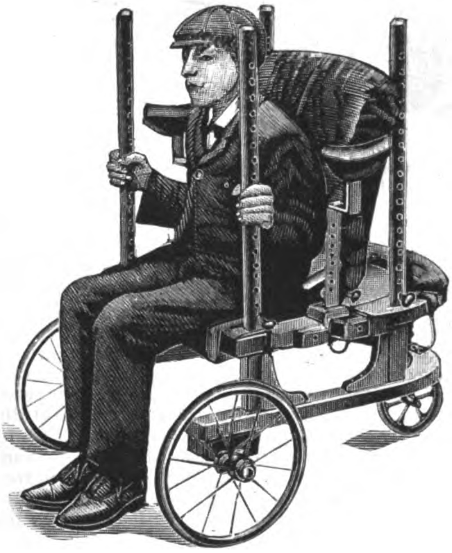
As regards the management of the convalescent during the resting period, time will not permit me to enter again into the details of the method which I have described to you on previous occasions. To build up the strength and to grow the tissues, there are two requisites: food and oxygen. We have all been taught as students to supply food; but not all of us sufficiently taught to supply the oxygen.

The earliest, the most indispensable, and the most profitable exercise for our bedridden convalescents is *the systematic exercise of the respiratory function*, which feeds and exercises the heart through its own perpetual stimulus, the work of the respiratory muscles. On the other hand, by improving the blood and the circulation, it improves the nutrition of bone, cartilage, muscles, and joints, and of all the organs. *Massage and resistance movements* are the next instalment to be provided for the patient whilst he is still confined to his bed. With these helps it is often possible to materially reduce the period of recumbency. Having secured this solid basis of respiratory and circulatory efficiency, the patient can soon be lifted out of bed without any fear of overstrain for heart, lungs, or limbs.

The Out-of-Bed Stage, and the "Convalescent Machine."

At this stage I have found considerable advantage from the use of a versatile commodity, for which I know no better name than that of the *Convalescent Machine*. Its construction was first suggested to me by a desire to secure for the adult the special advantages obtainable in infants and children with the "Baby Rest" and the "All Fours' Exerciser." No description has hitherto been published of these useful additions to the furniture of the nursery. But you may remember my having shown them to you at the Polyclinic; and I have also written an incidental reference elsewhere. (*a*)

Fig. 1.



The Convalescent Machine as a Wheeled Chair.

The purposes secured in these two appliances are: (1) Efficient *rest* with *varied posture*, and, when desired, with locomotion; and (2) *complete freedom of* the four extremities and of the head for every variety of movement, combined with complete support of the body, so that none of its weight is allowed to be borne by the limbs. In this respect they might be likened to a sort of "swimming board"

The general plan of the machine, best seen in Fig. 4, is that of a strong wooden, U-shaped, movable *upper frame*, capable of an extensive variety of horizontal positions by altering the place of the iron pins in the holes of the vertical wooden poles. These are firmly fixed in a lower U-shaped frame also made of wood, to which the wheels are attached.

The upper frame is padded in front for the tender hands of gout, of rheumatism, or of paralysis. It is

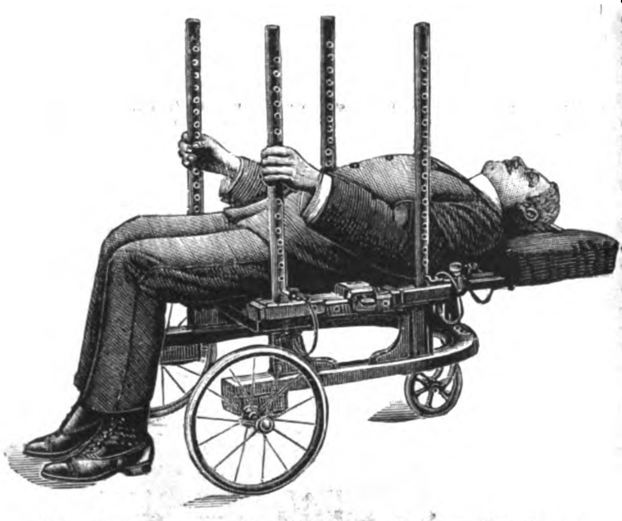
(*a*) Cf. Reports of the Society for the Study of Disease in Children. Vol. vii. P. 201. 1906-1907.

furnished at the sides with crutches capable of sliding up and down for the finer adjustment of their height. By taking out the pins they can be readily lifted out when not required.

The other parts of the machine are equally easy to handle. They consist: (1) of a removable padded seat, which simply lifts in and out of the upper frame; (2) of the head and shoulder support, which can be readily fitted as an horizontal extension to the front of the upper frame; and (3) of two metal rods (not shown in the illustrations) which slide out under the upper frame to support the legs and feet on a canvas-stretcher when the machine has to be used as a complete couch.

This preliminary description of the Convalescent Machine will help us to understand its varied uses, some of which are illustrated in the figures.

Fig. 2.



The Convalescent Machine as a Supine Couch, or Supine Exerciser.

As a Wheeled Couch, the machine cannot pretend to compete in all points with the most perfect modern pattern of couch. Nevertheless, it presents advantages besides that of mere compactness, and of its adaptability to most ages and sizes. The poles, though rather unsightly, are of practical service for leverage in all cases where the hands and arms can be used. And there is the other great advantage that the reclining convalescent can wheel the couch about for himself.

As a Wheeled Chair, the purpose of rest is fulfilled by arranging the head and shoulder support, as shown in Fig. 1, to serve as the back of a chair, and by lowering the crutches to a position of comfort for the support of the elbows. But special indications can also be carried out in connection with the lower limbs, with the spine, and with the shoulder-joint.

(1) The canvas-stretcher or leg-rest is available in all cases where elevation of the lower limbs is required. (2) The crutches can be used with due reservations to encourage a correct attitude of the spine during the period of sitting. And (3) with suitable adjustment of height and of padding they can be used for passive stretching of the axilla in cases of contraction.

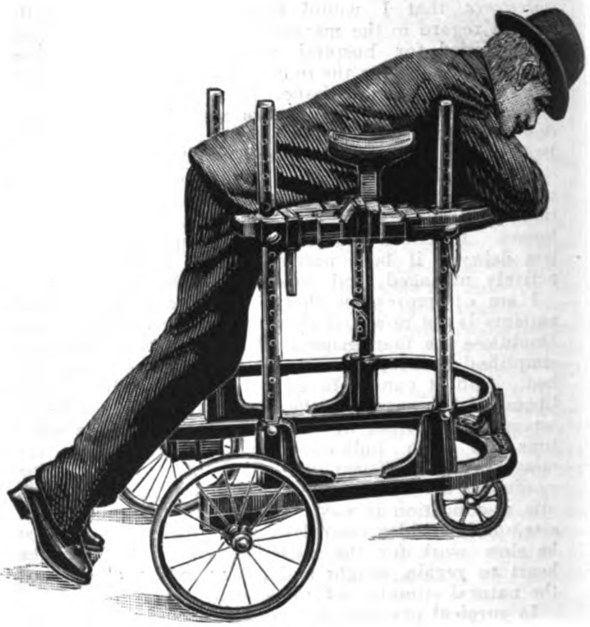
Exercise is the soul of convalescence, though rest is the indispensable basis, and its fundamental principle is *graduation of exertion*. This is taught us by the object lessons of Nature, when the immobility of prostrating disease gives way to the slighter movements in bed, such as turning, leaning up, and finally sitting up spontaneously. There, however, with adult convalescents the progression often stops; and unless given special opportunities many of their muscles remain unexercised. In children, putting aside special cases of disablement, Nature is not to be thwarted; and if they are confined to bed beyond the preliminary stage their muscular activities soon develop into acrobatics. It is only fair to say that "bed" is often the most convenient gymnasium we can offer them. But as any wheeled chariot has enduring fascinations for the young, a good deal of time might usefully be disposed of "on wheels."

So much for the special case of juveniles. The ordinary convalescent, if afforded a fair opportunity, will, like any infant placed on the "Baby Rest," find out for himself, or, rather, fall unconsciously into, the performance of those muscular movements of which he is capable without any stress or strain. It is obvious then that the earliest exercising function of the Convalescent Machine is that which it provides in the three positions of rest, the prone, the supine, and the seated. But the graduation of conscious and systematic exercise is the purpose for which it is specially adapted. With the "All-Fours' Exerciser" it shares the principle of "lifting off" the weight of the body, and of exercising the muscles in the "*unloaded state*." But it affords an additional advantage in the *weight-and-pulley attachment*, which can be fixed at the top of the poles, to exercise the limbs in the supine position on the plan of the *resisted movements*.

The application of these principles enables us to fulfil the two indications we had in view: the systemic or nutritional indication, that of improving the circulation and all the functions by movement; and the special or local indication, which aims at restoring strength and mobility to muscles and joints.

As a Wheeled Prone Exerciser, the illustration, Fig. 3, demonstrates the method of progressive re-education of disused mechanisms. The weight of the trunk rests entirely upon the machine, and the level of its support is so adjusted as to allow only a tip-toe touch of exertion for the muscles and joints of the lower limbs.

Fig. 3.

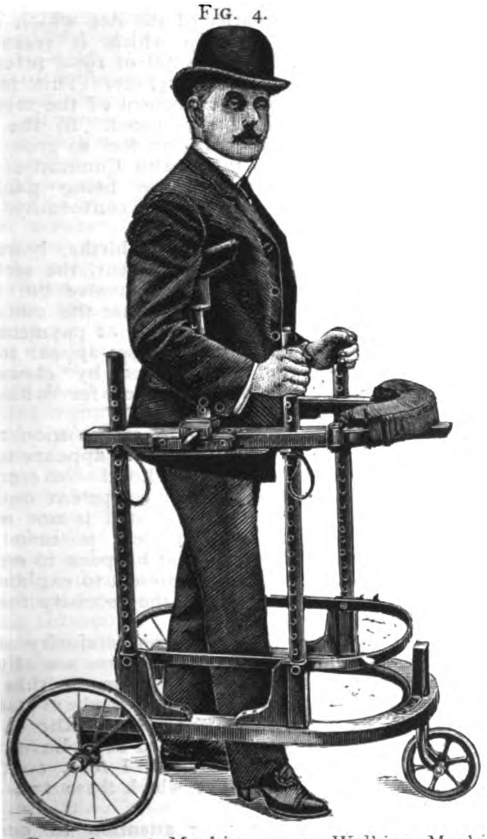


The Convalescent Machine as a Prone Exerciser, or (when lowered as in Fig. 2 and fitted with a Leg-rest) as a Prone Couch.

When used as a *Walking Machine* the same progressive principle is provided by the apparatus; and the adjustability of the crutches is found on trial to be most satisfactory.

Muscular exercise for the limbs and joints is by no means the only line of employment for the machine. *The treatment of the viscera* is one of its chief uses, as subsequent communications will show. Of all the positions the most valuable is the *prone position*, both for the abdomen and for the chest. And of all pulmonary diseases, those which will benefit most are bronchiectasis and the chronic catarrhal affections. By raising the posterior level of the supporting cushions higher than the anterior it is possible to obtain a declivity of the thorax in the prone attitude, that is to say, the ideal posture for the spontaneous drainage of the bronchial tree, of the larger bronchi, and of the trachea.

FIG. 4.



The Convalescent Machine as a Walking Machine, or "Crutches on Wheels."

Rest, which is the chief requisite at all stages of convalescence, is not always easy to enforce; and we must be prepared to deal not only with the normal restlessness of youth, but also with the *constitutional nervous restlessness* of some individuals. For both these classes the Convalescent Machine can lend us welcome help. It is possible to prescribe its employment for stated periods in the day either as a couch to rest the entire body, or as an armchair which combines with the repose some slight work for the loins.

The foregoing remarks have referred mainly to medical ailments and their convalescence. It is obvious, however, that facilities offered by the Convalescent Machine must prove of special service in the large group of *crippling and paralysing affections and lesions*, whether medical or surgical. It is unnecessary to enter into the details of their treatment, which would carry us too far; and it remains for me only to offer to Mr. John Ward, of 246, Tottenham Court Road, the thanks which he has so well earned by his skill and success in carrying out the construction of the Convalescent Machine.

NOTIFICATION OF BIRTHS ACT, 1907. (a)

BY E. W. HOPE, M.D.,

Medical Officer of Health, Liverpool.

FOR a great number of years the subject of infant mortality has engaged the attention not only of the medical profession, but, in fact, of all those engaged in dealing with questions affecting the public health.

Just twenty-one years ago I read a paper upon this subject in this Institution, and the views then expressed have been fairly borne out by subsequent experience. It is largely owing to the fact of the low birth-rate in France, and the consequent stationary condition of the population in that country, that very particular attention has been paid to the infant. As Mr. Broadbent expressed it, "France appears to be the only country which has discovered the baby. Contrast the lack of information as to births with the superabundant information as to the records of deaths, and one becomes aware of the curious paradox that death appears to be a much more important and interesting event than birth."

The appended table (Table "B ") gives the rate of mortality below five years of age, and also of infants under one year of age, and the figures are sufficiently impressive.

In the fulness of time, legislative and administrative measures have been devised in various directions, with a view, if possible, to lessen the loss of infant life. One of the most recent is the Midwives Act. I make but a single reference in order to say that the Act has proved an extremely beneficial one, and is gradually fulfilling the objects it was designed to accomplish.

The Act to which I wish to call attention now is one called "An Act to Provide for the Early Notification of Births," and the chief provisions of it are as follows: The Act is an "adoptive" Act; that is to say, the local authority may adopt its clauses in their area, or they may leave it alone, but the resolution of adoption cannot take effect until the consent of the Local Government Board has been obtained. It does not appear that the Local Government Board can prevent its adoption, but they may by order declare the Act in force in any area which has not adopted it.

The Act provides:—

(1) That it shall be the duty of the father of the child, if he is residing in the house at the time, and also the duty of any person in attendance upon the mother at the time of, or within six hours after, the birth, to give notice, in writing, of the birth to the Medical Officer of Health in the manner prescribed, namely:—

(2) The notice shall be given by posting a prepaid letter or postcard to the Medical Officer of Health, giving the necessary information of the birth within 36 hours after the birth, or written notice may be given if this is preferred. The local authority shall provide stamped addressed postcards containing the form of notice to any medical practitioner or midwife who applies for them.

(3) A penalty of 20s. attaches to failure to give notice.

(4) The notification required under this Act is an addition to, and not instead of, the requirements of any Act relating to the registration of births.

(5) The section shall apply to any child born after the 28th week of pregnancy, whether alive or dead.

(6) Any expenses incurred by the local authority in the execution of this Act shall be paid as part of the general expenses relating to public health.

There are about 24,000 births annually in Liverpool, and I reckon that some 15,000 of these are attended by midwives.

Obviously the Act is one which will primarily affect the medical attendant or midwife, for it is well known to all of you that when Acts of Parliament impose obligations alternatively upon one of two people, one of whom is the medical attendant, it is he who bears the brunt of the burden. This is the universal experience of the Notification of Infectious Diseases Act, and in this case there is no doubt whatever that the new Act will affect the medical man in the same way. Amongst the poorer classes the midwife will be the person from whom the notification will come.

The object in bringing the matter forward now is to ascertain whether the members of the Institution have any views as to the way in which the obligation imposed upon them can best be carried out with a minimum of inconvenience, and whether they have preference for any special form, either of letter or postcard, by which the intimation can be conveyed. If so, I will endeavour to meet the general wish in these directions. In the meantime I suggest the form here reproduced.

(a) Paper read before the Liverpool Medico-Chirurgical Society.

CITY OF LIVERPOOL.

NOTIFICATION OF BIRTHS ACT, 1907.

....................190....

To the MEDICAL OFFICER OF HEALTH FOR THE CITY OF LIVERPOOL.

Dear Sir,

I hereby notify that on ....

.... 190..........

....

residing at ....

was delivered of a { male / female } infant { living. / stillborn.

(Signed) ....

Address ....

....

N.B.—If notified by parent, the name and address of the person in attendance must be given below:—

Name ....

Address ....

....

Observations by Medical Attendant:—

....

....

I may explain that the ultimate object aimed at by this Act is to secure, by means of a trained and educated staff, that advice shall be available for the poor mothers who, but for such action on the part of the local authority, would have no one to advise them; it will also serve as a basis for important investigations affecting infant mortality, one of which the Home Secretary has already set on foot. The importance of the notification from the public health point of view, and the action which will follow upon it, will vary considerably in the different social classes. Amongst those, whether rich or poor, upon whom a medical man is in attendance, I anticipate that the medical man will indicate what action he desires, if any—much, in fact, as he now does in the notification of phthisis; and this circumstance renders it desirable either that the notification should come direct from the medical man when there is one in attendance, or that the notification, if made by the father, should state whether or no a medical man is attending. With regard to midwives, a greater discretionary power will, of course, require to be exercised.

When the notification is received, the next point to determine will be when the first visit of the visitor should be made in those cases in which a visit is needed, and upon this the opinion of the medical profession would be valuable. Our general experience leads us to the view that the infants of the poorer classes are for about 28 days after birth fed at the breast; but it would nevertheless be desirable, and in many cases necessary, to pay an earlier visit than this, perhaps at a period of about seven days after birth, unless circumstances suggest that an even earlier visit is desirable. The circumstances which would suggest an earlier visit are those in which there is extreme poverty, and where perhaps the mother may be without any help whatever in attending to the infant, or even to the ordinary domestic necessities. The actual date of the first visit, therefore, after confinement, must, I think, vary, but I must point out that one-fourth of the total infant mortality takes place before the first month is reached, and more than one-half of these deaths occur during the first week after the birth of the infant; thus, last year there were 4,137 deaths of infants under 1 year; of these, 1,057 were below 1 month, and 571 below 1 week of age.

It must not be supposed that visiting of this character is a new thing in this city. Three years ago I inaugurated a similar system of visitation, but hitherto the long delay in receiving the notification of the birth has handicapped the work; under this system the notification of births, when received at the Education Office, were copied by members of the staff of the Health Department, and the addresses in certain districts were visited. I show you the forms upon which the results of those visits have been recorded.

I turn now to a peculiarity of the Act which calls for a word of observation, in which it resembles certain clauses in the Midwives Act of 1902, referring to medical aid in time of emergency. This is the omission of any provision for payment of the medical man or midwife for services rendered. In the case of the Midwives Act, the omission was so gross that when I pointed it out to the Health Committee they at once assented to a uniform fee being paid to medical men who gave assistance in conformity with the requirements of the Act.

In the case of the notification of births, however, the circumstances are somewhat different, the services rendered are very much less, and involve but little time, and whilst I am of opinion that the omission from this Act of any specific mention of payment for the service is a regrettable one, it does appear to me that such payment would be covered by clause 1, section 6. Upon this point I will confer with the Town Clerk.

I have one final observation to make upon these omissions, and that is, that their cause appears to me to be a very simple one. The Local Government Board, as you know, has a highly competent medical staff, but, unhappily, that medical staff is not represented upon the Board. Its business is merely to report; and everybody knows what happens to reports when the author of them is not present to explain, to amplify, or, if necessary, to urge the necessity for the recommendations made.

We may safely assume that the great majority of the measures in which the medical profession are alluded to, or by which they are affected, come within the purview, directly or indirectly, of the medical staff of the Local Government Board. Until the Local Government Board is so reconstituted as to have upon it medical representatives, we shall, I fear, continue to labour under the difficulties which these two Acts of Parliament illustrate.

In conclusion, I invite your attention to one or two diagrams on the screen, illustrating the fact that the very early age periods are the fatal ones in this city, and that after five years of age the differences in the mortality rates of all England and Wales and Liverpool are but slight.

TABLE B.—INFANT MORTALITY, YEAR 1905.

	Per 1000 Births.	Per 1000 Survivors.				
	Under 1 year.	1 to 2 years.	2 to 3 years.	3 to 4 years.	4 to 5 years.	All ages above 5 years.
England and Wales... ...	128·15	37·50	15·07	9·82	7·28	11·9
Liverpool ...	154·08	58·51	22·49	15·58	11·84	12·9

Liverpool: At all ages above one year, death-rate = 14·5 per 1,000.

The year 1905 is taken for illustration, but the three years 1905, 1906, and 1907 taken together show very similar results.

CLINICAL RECORDS

A NON-TYPICAL CASE OF LUPUS DIAGNOSED BY CALMETTE'S TUBERCULIN METHOD.

By DAVID WALSH, M.D., EDIN.,

Senior Physician, Western Skin Hospital; Physician, Skin Department, Kensington General Hospital.

A. B., æt. 24, sent early in December by Dr. Arthur Douglas, Enfield Lock. Patient complained of a rash on nose and face of two months' duration. Good family history. Patient well nourished, and general health always good on the whole; had enteric fever at 19 years. Has bad teeth, and suffers from chronic dyspepsia. There had been a few irritating papules on face for years past, and small scars had been left by them, especially on the lower right cheek, and at the time of first examination several acne spots were seen on forehead, etc.

The rash on the nose first appeared about six months ago. It began as a papular rash, and was seen three weeks after its appearance by Dr. Douglas, who, after a short trial of calomel, scraped it and applied pure carbolic acid. Little benefit followed, and later some more spots appeared on cheek and nose.

Present Condition.—The lower half of the front and sides of nose is covered with a bright red rash; the margins extend halfway towards cheek, and are fairly well defined, with some outlying patches. The edges may be said to have in parts rather more marked papules than the rest of the main patch. The latter nowhere shows scarring, but is studded with numerous small comedones of uniform size, which may be seen projecting from the surface. There is nowhere to be seen anything resembling an apple jelly nodule. On the cheeks are a few discrete papules over the malar bone, and more on the right (about half a dozen) than on left. These are darker in colour than the rash on nose; about the size of a hemp seed; and almost level with the surface. Over the left naso-frontal region was a smooth, dull-red, slightly-raised patch, which was certainly suggestive of lupus vulgaris. The ears were free.

The patient was first treated with mercurial and antiseptic applications in the form of plaster. As there was not much improvement after a few weeks, the whole of the patches and outlying papules were scraped and painted with pure carbolic acid. As the result of this was not altogether satisfactory, it was determined to test the patient with Calmette's diagnostic tuberculin. Accordingly, a minim of the fluid (Martindale's) was dropped into the right eye, the conjunctiva of which was previously ascertained to be in a healthy state. (The mucous membrane of the left eye was in a condition of mild catarrhal conjunctivitis.) Some 12 hours later a reaction appeared in the right eye and attained its maximum about 20 hours after the application, with much redness, photophobia and lacrymation.

Remarks.—This rash was one of the borderland kind so far as appearances went; one of those transition forms on which the French writers lay a good deal of stress. In these atypical eruptions it is impossible for even the most experienced to be certain of the diagnosis, except under prolonged observation. The rapid settlement of diagnosis, therefore, by so simple a method as that afforded by Calmette is obviously of considerable practical value. In this case the balance of probabilities lies in the supposition that the skin rash is of a tubercular nature. Although it may, of course, happen that a patient may have a non-tubercular skin rash, but may furnish the ophthalmic reaction of Calmette owing to latent tuberculosis elsewhere. There was no reason to suspect the latter condition in A. B. The patient was accordingly informed that it was desirable to repeat the scraping at an early date. At the next operation it is proposed to scrape the whole surface and to include the discrete papules on the cheeks in the process, and afterwards to apply the acid nitrate of mercury..

A few words may be added for the benefit of those who may not have had an opportunity of testing this new method, which promises to be of special value in diagnosing early or obscure cases of tubercular infection. At present there is much doubt as to the precise relation of lupus erythematosus to tuberculosis. Several cases of that malady, however, have been already found to give the ophthalmic reaction. An interesting case of Bazin's disease (erythema induratum) in a young woman, æt. 21, with a tuberculous family history (two aunts on mother's side). Dr. J. M. H. MacLeod (a) obtained a positive reaction of an acute character coming on six hours after the instillation of one drop of Calmette's solution into the conjunctiva.

Professor Calmette first published his method of administering tuberculin for diagnostic purposes in June, 1907. It was brought to the notice of English writers by Mr. Sydney Stephenson (a). Two recent American writers, Drs. Frank Smithier and R. P. Walker (b) have fully published a collection of cases by French writers, in which a positive reaction was obtained in 176 out of 185 cases clinically tuberculous, with 9 negative reactions. Of 28 cases doubtfully tuberculous, 21 gave positive and 7 negative reactions. Of 188 persons suffering from disease not tuberculous, and including a proportion of apparently normal individuals, 186 gave negative and only 2 positive reactions.

OPERATING THEATRES.

GUY'S HOSPITAL.

Operation for Old Fracture of the Radius and Ulna.—Mr. Arbuthnot Lane operated on a boy, æt. 12, who had sustained a fracture of the radius and ulna above the middle of the shaft six months previously. The fractures had been produced by direct violence, and were on the same transverse level. Mr. Lane pointed out that, as so often happens in this form of fracture, there had been some overriding of the fragments, which had united so that their axes formed a considerable angle, and the functions and appearance of the forearm were very much depreciated. The ulnar junction was first exposed and divided in an oblique plane, so that the angle formed between its fragments could be subsequently obliterated. The seat of the fracture of the radius was then freely opened up, and a wedge of bone was removed. In consequence of this the axes of the fragments were got into perfect continuity. They were secured by two small dumb-bell plates by means of four screws, two of which crossed the others at right angles and rendered the fragments immobile and any displacement impossible. The ulnar fragments were then rotated upon the obliquely-cut plane till their axes were continuous, and they were retained in this position by an axial screw and a controlling metal plate and screws. Mr. Lane said that these operations for fractures which have united in bad positions are infinitely more difficult to perform than are those for recent fractures, for the reason that in the latter the surgeon can fit the fractured ends accurately into position, and can ensure perfect continuity, while in the former the operator has to deal with deformed bones, which he has to divide in three, and perhaps four, places, and also in the young subject with a callus extending along the whole length of the fragments, altering the form of the bone, and making it most difficult to recognise the relationship of the axes of the fragments to one another. Again, in recent fractures, the length of incision is not necessarily so great, and the chance of doing damage is very much less. Indeed, the risk of interference in expert hands is very small indeed, while the benefits which the patient derives from a perfect restoration of his anatomy is enormous.

Excision of Rectum.—The same surgeon performed the second stage of an operation for excision of the rectum for malignant disease. This patient, Mr. Lane said, had seen two eminent surgeons three months previous to his admission to Guy's, and he had been informed that the condition was inoperable. The growth commenced about an inch above the anal aperture, and extended around the bowel for some distance. The pain and distress to the patient from the condition were very great. A fortnight before Mr. Lane had opened the abdomen three-quarters of an inch to the left of the middle line by an incision extending from the umbilicus to the symphysis pubis. The upper limit of the growth in the rectum was defined, and the extent of the glandular infection in the mesentery determined. The sigmoid was freed from the adhesions that bound down first the meso-sigmoid and later the bowel itself into the iliac fossa. Then Mr. Lane pointed out precisely the same in character and in mode of production as those which develop in chronic constipation, which he has described fully in his papers on the operative treatment of this condition. The bowel and mesentery having been freed, the former was turned out through the abdominal incision, the mesentery controlling the rectum above the line of the growth, and the sigmoid at its lower part was divided. The sigmoid was divided with the cautery, sufficient length being left protruding to allow of a suitable drainage apparatus being connected. The rectum was then ligatured immediately above the growth, and after its division by the cautery above the ligature the latter was prolapsed into and buried by means of purse-string and other sutures in the rectum. The peritoneum covering the bladder and sides and back of the pelvis was so united by gut sutures as to shut off the portion of the true pelvis containing the remainder of the rectum from the general peritoneal cavity. The abdominal incision was then rendered firmly secure, the orifice of the sigmoid appearing just below and to the left of the umbilicus. At the present operation the remainder of the rectum with the growth in its wall was carefully dissected out from adjacent structures, no bone being divided in doing so. The patient is progressing most satisfactorily, and has suffered neither pain nor distress in consequence of the operation.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Clinical Section.

Meeting held Friday, February 14th, 1908.

The President, Sir Thomas Barlow, in the Chair.

Mr. J. Paul Roughton showed a case of

LYMPHANGIOMA OF FACE.

M., æt. 11. The whole of the right side of the face, with the exception of the region below and to the right of the mouth, was occupied by a swelling of a doughy consistency, the upper eyelid especially being very swollen. The swelling crossed the middle line on the forehead and upper lip. There were many cords and knots distributed throughout the swelling, especially on the forehead, over the parotid, and in the cheek, and there is a distinct cord running immediately behind the facial artery over the ramus of the jaw. There was no pulsation. Eight years ago the mother had noticed that the right eye looked smaller than the left, and shortly afterwards the outer canthus began to swell, from whence the swelling had gradually spread.

Mr. R. J. Godlee suggested that the case was one of plexiform neuroma, a view that was strongly supported by Dr. Parkes Weber. Mr. W. G. Spencer advised operation, and referred to a similar case that he had successfully operated on. Dr. G. A. Sutherland had shown a similar case to the Society two years ago; in his opinion also the condition was one of neuroma.

Dr. Herbert French showed a case of

TUMOUR OF MEDIASTINUM (? HYDATID).

The patient, a woman, æt. 42, looked perfectly well, and her only complaint was that she could not see properly with her left eye. There was complete paralysis of the left cervical sympathetic nerve. This dated back for over two years. There was ptosis of the left upper eyelid; the left pupil was continuously small; the patient could not blush upon the left side of her face, and when she perspired the right side of her face sweats, but the left did not. There was distinct fulness of the left external jugular vein, and of the veins over the upper part of the left chest in front. There was complete absence of breath and voice sounds over the region where the upper two-thirds of the upper lobe of the left lung ought to be. The conclusion was that, in the region of the left upper lobe, there was a mass nearly as big as an orange, large enough to displace or destroy the lung there, to extend back far enough to compress the cervical sympathetic nerve, and forward enough to compress the left innominate vein.

Dr. C. J. B. Williams suggested that the growth might be a lymphoma, of which he had seen two examples. Dr. A. C. Garrod recalled a similar case he had seen in a child, and which proved to be a hydatid.

Mr. R. J. Godlee showed a case of

OLD FRACTURE OF HUMERUS, WITH OSTEO-ARTHRITIS OF ELBOW.

Patient was a man, æt. 34. Twenty-one years ago he had injured his right elbow. Three and a-half years ago a small, painful swelling appeared on the elbow. Soon afterwards a swelling appeared on the inner side of the back of the forearm, 2 in. below the internal condyle, which increased in size during the last year till it reached that of a walnut. It proved to be a "ganglion " with a thin wall, the pedicle of which extended up towards the joint along the internal intermuscular septum. The skiagram shows an old fracture of the internal condyle and irregular masses of bone attached to both the upper ends of ulna and radius. The movements of the joint were almost perfect. The case suggested that an injury to a joint in youth might determine the onset of osteo-arthritis later in life. No signs of osteo-arthritis had been discovered in other joints.

Mr. R. J. Godlee also showed a case of

OLD-STANDING DISLOCATION OF PATELLA, WITH OSTEO-ARTHRITIS OF KNEE.

The patient, a man, æt. 50, said that his right knee had been out of shape since birth. It had not caused him much, if any, inconvenience until he had a blow upon it six months ago, since which time his knee had been painful. On flexing the knee the patella would slip right over to the outer side of the joint. There was marked genu valgum, and the signs of osteo-arthritis were unmistakable.

Mr. T. M. Openshaw agreed with Mr. Godlee with regard to the significance of past injury to joints, both recent and remote, in the causation of monoarticular osteo-arthritis. Dr. Seymour Taylor described a ganglion that had developed on his own forefinger in connection with a traumatic osteo-arthritis. Dr. F. J. Poynton said that such trauma was not essential but predisposed to the affection. Intravenous injection of organisms sometimes produced osteo-arthritis strictly confined to one joint. Dr. A. E. Garrod said that trauma played a part in most joint affections, notably in gout, and also in infective arthritis.

Dr. Seymour Taylor showed a case of

RUPTURED AORTIC VALVE.

The patient, a man, æt. 34, complained of tightness across the chest, a choking sensation on exertion, and a buzzing noise in the chest, which he heard best when lying down. These symptoms supervened suddenly after the strain of lifting a heavy weight. He had twice suffered from lead colic. He had a typical blue line at the edge of the gums. A diastolic thrill was felt, most intense over the second and third spaces on each side. On auscultation a loud murmur was heard, loudest over the aortic area, diastolic in period, and musical in tone. The musical note corresponds to about B below the staff. The murmur was heard all over the chest, and even over the upper thirds of the humeri. The condition of the valve was probably one of perforation of one cusp rather than of detachment or true rupture.

Sir John Broadbent had observed a case of traumatic rupture of the aortic valve, which was followed by acute heart failure and death within a month. Dr. F. J. Poynton had seen two cases followed by autopsy; in these there had been no pain and but little general disturbance at the time of the accident. Dr.

C. J. B. Williams had also made autopsies on such cases. He thought that a musical murmur was due rather to a free tongue depending from the cusp. Dr. Parkes Weber said that it was sometimes doubted whether rupture ever occurred apart from malignant endocarditis; he had performed an autopsy however on a case that was due neither to this nor to accident. Dr. Seymour Taylor, in reply, said that a free tongue should produce a double murmur, not a single one.

Dr. Arthur Latham showed a case of

CASEATING PULMONARY TUBERCULOSIS TREATED BY TUBERCULIN (T.R.) AND HORSE SERUM, BOTH ADMINISTERED BY THE MOUTH.

Dr. C. J. B. Williams congratulated Dr. Latham on the result of his treatment.

Dr. F. Parkes Weber showed a case of

SPURIOUS (?) ACROMEGALY.

The patient was a woman, æt. 46, rather corpulent, and very anæmic. Her face and head, with the large lower jaw, prominent chin, and big nose, could have been used as a model for an illustration of acromegaly. She had thick, fleshy hands and thick fingers, but she had no ocular symptoms of acromegaly, and her occasional headaches and shortness of breath seem to be connected with her anæmia, which in its turn may be accounted for by frequent hæmorrhoidal bleeding, from which she had suffered during the last six or seven years. There was no evidence of any progressive change having occurred in the shape or size of the hands, feet, face, skull, or other bones of the body since she ceased growing at the ordinary age. An old photograph (the only one obtainable for comparison), which was taken three or four years ago, shows her face looking just as it does now.

The President asked whether a skiagram had been taken? Dr. Weber replied in the negative.

Mr. H. A. T. Fairbank showed a case of

A LARGE SARCOMA OF THE THIGH IN A MALE CHILD, AGED FOUR.

The duration was two months. The growth did not proceed from the bone. Deep glands were involved, and the growth was inoperable.

Baker and Forbes

Mr. W. G. Spencer showed a case of

LATERAL CURVATURE RAPIDLY DEVELOPING IN A BOY.

M., æt. 3, was all at once noticed to have a marked lateral curvature. He had a marked left thoracic and lumbar scoliosis, and walked with lordosis; both of these curvatures disappear when he is suspended by the arms. The muscles of the left side of the spine appeared unduly weak, and the abdomen was irregularly protuberant.

Mr. R. P. Rowlands showed a

CASE OF EXCISION OF THE BODY OF THE SCAPULA.

M., æt. 35, from whom the whole of the body of the left scapula was excised for enchondroma fifteen months ago. It was possible to save the coracoid process, with its important muscles and ligaments, the glenoid cavity with the capsular ligament of the shoulder-joint, and the acromion process, with the attachments of the deltoid and trapezius to it. The patient showed that both the functions and the deformity following this procedure were much less than after complete excision of the shoulder-blade. The man had been able to do his work as a painter's labourer at Guy's Hospital from two months after the operation. It was claimed that preservation of the processes and glenoid cavity was both practicable and advisable in preference to complete excision of the scapula for inflammatory conditions and innocent growths, and possibly for some malignant growths.

Dr. Frederick E. Batten and Dr. J. Graham Forbes read a

NOTE ON TWO CASES OF GAERTNER INFECTION IN INFANTS.

Both cases were clinically ones of acute diarrhœa, with no special features. The first one was recognised during life, for the blood reacted to Gaertner's bacillus but gave no Widal test. At the autopsy a number of deep, small, irregularly situate ulcers were found in the small intestine. Gaertner's bacillus was isolated from the spleen, blood and mesenteric glands. The second case gave no Widal; no agglutination with Gaertner's bacillus was tested, but the bacilli were isolated from the stools. Dr. Forbes detailed the cultural distinctions between Gaertner's and allied micro-organisms.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Anatomy and Physiology.

Meeting held Friday, January 24th, 1908.

Professor A. Fraser in the Chair.

THE ANATOMY OF THE ILIAC COLON IN RELATION TO HERNIA.

Dr. R. A. Stoney read a paper on the above. The subject was suggested by three cases which were recently seen by the speaker, where a hernia of this portion of the large intestine had occurred. Two were hospital patients who were operated on for the radical cure of left inguinal hernia, and in each case, the sac on being opened, was found to contain a piece of the large intestine invaginated through the posterior wall, the sac being incomplete. The third case was an old dissecting-room subject (male) with a large femoral hernia on the left side, which was found to contain, in addition to about three feet of the small intestine, a loop of large intestine which proved to be about three inches of the iliac colon. Though the iliac colon usually has no mesentery and lies far back in the iliac fossa, there are two conditions sometimes present which may increase the liability of this part of the intestine to become extruded from the abdomen—first, the presence of a mesentery (ten per cent., according to Jonnesco); and secondly, a low position in the iliac fossa, the intestine running along in close relation to Poupart's ligament. There are three ways in which a hernia of the iliac colon may occur:—(1) It may be drawn down into or through the inguinal canal by an extra attachment of the gubernaculum—this is the congenital hernia; (2) it may be drawn down by a protrusion of the peritoneum covering it in the formation of the sac of an ordinary hernia; (3) there may be a giving way or lengthening of the supporting apparatus of this portion of the intestine, and a subsequent protrusion of it by the expulsive action of the abdominal muscles. The relations of the peritoneum forming the sac and covering the gut will differ according to the mode of formation of the hernia. In the congenital form the sac is probably always incomplete, as there is merely a displacement of the gut and the surrounding peritoneum into the scrotum, so that they maintain their normal relations to one another—*i.e.*, the peritoneum only partially covers the intestine. In the second form also the sac is probably always incomplete, as even if the gut had a mesentery to start with its left or lower layer would be taken up first in the formation of the sac before the gut was drawn into the hernia. Unless the hernia is of an enormous size this form is only likely to occur if the intestine has an abnormally low position. In the third form the presence or absence of a complete sac will depend on which of the two factors is at work. If it is due to a giving way of the attachments of the intestine it slides down behind the peritoneum and the sac is only partial. This may be truly described as a "hernia *en glissade*." If, however, it is due to a lengthening or stretching of the support of the intestine, the latter either has a mesentery to start with or obtains one which finally becomes long enough to allow the gut to reach the internal abdominal ring and be herniated like any other portion of intestine. In this case, of course, the sac will be complete—in fact, it is probably only in the hernia formed in this way that the sac is ever complete.

Professor M'Loughlin said that the attachment of the gubernaculum to the peritoneum of the iliac fossa and the drawing down of the testis on that peritoneum was the general rule. It was a rare event to have it left behind. If the pulling of the gubernaculum on this peritoneum was to be considered as the sole cause of the congenital variety of hernia of the iliac colon we should expect to find this form of hernia a common one; but, as stated by the lecturer, it is one of rare occurrence. The cause, in consequence, is more likely to be *rarely* present. Now, in the fourth month, when the gubernacular bundle is beginning to push its way through the abdominal wall into the scrotum, the hind gut is provided with a mesentery. Should that mesentery be *unusually* long, especially about its centre or iliac colon portion, the free gut will swing low in the iliac fossa and the future iliac colon will come to lie in the dangerous zone beside the internal abdominal ring. Fusion of the mesentery with the peritoneum of the iliac fossa (as is the rule) may then take place, and the fusion will be with the peritoneum close to the opening in the wall into which the testis is passing. That peritoneum will be drawn down into the opening by the action of the gubernaculum, and so the gut will pass down the canal in the wall of the hernial sac. The cause of the congenital form is thus more likely to be a two-fold one —(1) The *accidental* lengthening of the mesentery of the mid-gut; (2) the action of the gubernaculum—the first being the determining factor.

Dr. **Stoney**, in reply, said that Professor M'Loughlin's suggestion was extremely interesting, and was quite as probable an explanation as his own.

Mr. **Adrian Stokes** exhibited a foetus showing transposition of viscera with a tricoelian heart, and gave the following brief account of the specimen:—The specimen which I have here to-night was obtained by Dr. Jellett in 1896, and was shortly described by him in the *Lancet* of 1897 as a case of transposition of the viscera with a tricoelian heart. Last year Professor Dixon very kindly gave me the opportunity of dissecting the specimen which had previously only had its thoracic and abdominal cavities opened. It soon became apparent that there were present further abnormalities which, I hope, will make it in some way worthy of your attention. The fœtus is well formed, and lived for a few minutes; the viscera and great vessels show complete transposition; the heart has a single large ventricle and two auricles. It is very remarkable that the left or systemic auricle has no direct communication with the common ventricle, its blood passing through a large patent foramen ovale into the right or pulmonary auricle in order to reach the ventricle. This must be an extremely rare condition. There have been a few cases recorded in which the pulmonary auricle did not communicate with the ventricle, but none, so far as I can find, in which the systemic auricle did not do so. The only other condition which I desire to note is that the pulmonary artery lies behind the aorta, a condition which is not accounted for by the general transposition of the viscera. Professor Young lately described a very interesting case of a tricoelian heart in a man of about 37 years. In it the chambers of the heart were in their normal positions, but the aorta arose, he believes, in front of the pulmonary artery. The condition of transposition of the viscera is rare. But few cases have been exhibited in Dublin, among which the best known case is the one exhibited by Professor Fraser before the Academy of Medicine in 1894. The condition of the heart is unlike any case of which I can find a record.

Professor **Fraser** exhibited and made remarks upon—

(*a*) THE HEMISPHERES OF AN ENCEPHALON, WITH WELL-MARKED INTERRUPTION OF BOTH CENTRAL SULCI.

The isthmus which connected the anterior and posterior central gyri lay on the same level as these gyri, and somewhat nearer the medial than the lateral ends of the sulci. The width was slightly over 1 c.m. This condition of the central sulcus is said to be rare. Professor Burt G. Wilder, in his essays—Vol. VIII., p. 158, and Vol. IX., p. 108, of the "Reference Handbook of the Medical Sciences"—gives the number of recorded cases as ten or twelve. He illustrates a case where the central sulci were interrupted (as in the above) in the hemispheres of a philosophical writer of some standing.

(*b*) A DUODENUM OF UNUSUAL FORM.

The third or transverse portion, instead of passing across the structures in front of the vertebral column in the usual manner, passed upwards on the right side behind the second or descending portion as far as the foramen of Winslow, thus forming a U-shaped loop, the two limbs of which could only be seen from the right side. Each limb measured slightly over 10 c.m. At the level of the foramen of Winslow the ascending limb passed across behind the superior mesenteric artery to the left side, and then formed the ordinary duodeno-jejunal flexure. The common bile duct passed between the descending and ascending limbs of the loop. The root of the mesentery had its origin from the duodeno-jejunal flexure from the processus uncinatus of the pancreas, and from the sharp bend formed by the descending and ascending limbs of the loop.

(*c*) ON THE MAIN ARTERY OF THE LIMB PASSING DOWN ON ITS POSTERIOR ASPECT.

Professor Fraser had observed this on the left limb of a middle-aged female during the summer session of 1907. He expressed regret at being unable to show the specimen, which he had thought to be well preserved until a few days before the meeting, when he found that in consequence of some inattention of the anatomical attendant it had gone astray. In this case the inferior gluteal artery was the size of the common femoral. It accompanied the great sciatic nerve and became the popliteal at the back of the knee. This latter vessel had the ordinary distribution. On examining the front aspect of the limb the external iliac was found to be smaller than ordinary, but of some size, until as common femoral it gave off its deep division. The superficial was of slight calibre, and was lost in small branches at the knee. Unfortunately he did not at the time examine the course of the veins. According to Quain, this form of distribution has been recorded ten times, but none of the sources are given. On turning to Henle's *Gefässlehre*, Professor Fraser found on pp. 303 and 312 a case illustrated (from Dubrueil) exactly similar to the one noted above. Also cases that have been described in English—Green (*Lancet*, February, 1832), who described a French specimen (as Fagge notes); Professor Ellis (*Med. Chir. Trans.*, Vol. XXXVI., p. 439), double, but in malformed limbs; and, finally, that of Fagge (*Guy's Hospital Reports*, Vol. X., p. 151), where an aneurysm had been found on the artery. Mr. Fagge considers that the cases recorded by Cailliard and Dubrueil were written from the same specimen, although at an interval of years.

Professor **M'Loughlin**, in discussing the latter communication, stated that only that morning, in his dissecting-room, he had seen two examples of portion of the abnormal artery described by Professor Fraser On *each limb* of a female subject the following was shown:—(1) The normal sciatic artery coming out of pelvis internal to sciatic nerve, and running down in superficial fascia. (2) A *second artery* (the abnormal one) coming out of the pelvis, through a 2-inch long cleft in the sciatic nerve and running down deep to the biceps to the popliteal space. Here the artery of the right side communicated with the popliteal artery by a branch about the size of a small digital artery.

DORSAL ORIGIN OF THE RIGHT SUBCLAVIAN ARTERY, WITH ASSOCIATED VASCULAR IRREGULARITIES.

Professor **M'Loughlin** exhibited a case of above. The right subclavian artery arose from the lower part of the arch opposite the disc, between the third and fourth vertebræ. It was bulbous and wide (24 mm.) at its origin; then, passing behind œsophagus and trachea, its anterior wall was deeply cupped, the posterior bulging markedly, so that the vessel would be crescentic on section. The vessel ran upwards and to the right, crossing in the middle line the disc between the second and third vertebræ. Its calibre was here much reduced, the tube—although flattened—measuring 13 mm. It now ran up the side of the body of the second vertebra, and, opposite middle of the body of the first vertebra, gave off a very large vertebral artery, the remaining three branches coming off the artery 1 cm. further on. The internal mammary was large, the superior intercostal small, and the thyroid axis small. The length of the artery up to origin of vertebral was 6.25 cm.; the whole of the first stage 7.50 cm. Its calibre just before origin of vertebral was 10 mm. The small superior intercostal artery gave off a profunda cervicis branch, which passed back *below* inner end of first rib, and not, as is usual, above it. The branch to the second space was joined, as is frequently seen, near the posterior end of the space by a small artery, which came up across the body of the third vertebra and was found to arise from a small first aortic intercostal, which was itself a branch of a very large right bronchial artery. This small artery linking the aorta (through its first aortic intercostal branch) with the subclavian (through its superior intercostal branch) has been held (just as the small aberrant artery which is occasionally seen linking the aorta directly with the subclavian) to represent in miniature the right dorsal aorta between the fourth arch and the point of fusion of both dorsal aortæ to form the descending aorta; but its presence in this specimen *in association with the irregular subclavian*, which is a persistent right dorsal aorta, is in contradiction to this view. This occasional aberrant theory, however, runs a course similar to that of the irregular subclavian, and should certainly be regarded as a vestige of the right aorta. Of other arterial irregularities present in this subject two may be specially noted. (1) The lingual artery was a very small twig arising a short distance above a small superior thyroid. It ran up to the hyoglossus, where it gave off its suprahyoid branch, and ended under the posterior part of that muscle by ascending in the position of a dorsalis linguæ branch. The greater part of the lingual area was supplied by a large artery which came off a large submental branch of facial. This artery pierced the mylohyoid far back, ran forwards on surface of anterior part of hyoglossus, giving forwards a sublingual branch, and backwards—under anterior border of muscle—a dorsalis linguæ branch. It then ascended to under surface of tongue, where it ran in the intermuscular cleft, as the ranine artery, to meet the opposite ranine at the tip of the tongue. The opposite lingual artery was normal. If we regard the lingual artery as a prolongation from the ventral end of the second aortic arch, and the facial artery from the end of the first aortic arch, then our abnormally constituted lingual artery represents two arteries, one of the first arch and one of the second arch, brought together about the middle of the tongue, or just about the line to which the second arch portion of the tongue reaches forwards to embrace the tuberculum impar and first arch portion of that organ. (2) The *vertebral* artery arising from the irregular subclavian was very large, the left vertebral very small. Both ran normal courses, and formed the basilar at lower end of pons. The left vertebral was a very slender twig at the point of union. At the upper end of the pons nearly the whole artery turned to the left as the left posterior cerebral artery, a small branch only going out to the right; the posterior cerebral of right side being mainly formed by a very large posterior communicating artery from the internal carotid. There was no direct communication between the internal carotid and the posterior cerebral arteries on the left side, the posterior communicating artery being but a very small twig which failed to reach the posterior cerebral. Associated with the irregular subclavian artery was a *thoracic duct* which, as is usual in such cases, ended on the right side of the neck. The duct lay in the middle line over the twelfth dorsal vertebra, passed to left over body of eleventh vertebra, and then ran up on right side of aorta, crossing the origin of the large right bronchial artery. Opposite the fourth dorsal vertebra it divided into two parts, which swept round in a circle and soon reunited, and then the duct turned over to the right (directed by the subclavian trunk which lay on its left), lying on third and second vertebræ. Then crossing over the front of the subclavian artery, half an inch below and internal to origin of vertebral and outside the vagus nerve, it passed up to end in the outer and posterior aspect of the internal jugular vein about one-third of an inch above junction with subclavian. A small lymph vessel, corresponding to the jugular trunk, opened just beside it into the jugular vein. No trace of a thoracic duct could be found on left side of neck, but on examining upper part of posterior wall of thorax on left side a large vein was seen running over the heads of the ribs. It opened above into the left end of the left innominate vein, and at its lower end turned transversely across disc, between seventh and eighth dorsal vertebræ, to end in ventral azygos major. It drained the upper eight intercostal spaces of the left side.

UNUSUAL POSITION OF LARGE INTESTINE.

Professor **M‘Loughlin** also called attention to the unusual position of the large intestine in the same subject. The ascending colon lay altogether in the iliac fossa, the cæcum was in the pelvis, and the descending colon was buried in a recess behind the lower third of the kidney and deep under cover of the psoas lower down.

IRREGULAR DISPOSITION OF THE HIND GUT DIVISION OF THE COLON.

Professor **M‘Loughlin** gave an account of a case of the above which he had seen recently in the dissecting-room. From the splenic flexure the colon ran down in its normal position to the iliac fossa. Near outer border of psoas it turned sharply on itself and ran straight upwards on the mesial side of the first tube. The second tube was provided with a short mesentery. Reaching the front of the lower part of the kidney, it again turned sharply and ran down along inner side of second tube, and, dropping over brim of pelvis just behind iliac bifurcation, it turned almost immediately backwards into curve of sacrum, where it soon lost its mesentery and became the rectum. The second and third tubes were obviously the sigmoid flexure, and the unusual position was probably due to the fact that the middle portion of the mesosigmoid failed to grow in proportion to the upper and lower parts, and that, in consequence, during the growth of the lumbar region, the central part of the flexure was left stranded high up in the position of the second bending over the lower end of the kidney. The line between the second and third tubes lay immediately over the course of the ureter, and the shallow recess beneath the second bending already noted might be regarded as an unusually highly placed intersigmoid fossa.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Clinical Evening.—Meeting held February 13th.

Mr. Treacher Collins, F.R.C.S., in the Chair.

Mr. L. Paton showed a case of detachment of the retina treated by operation. The patient had been sent to the National Hospital for the Paralysed with the diagnosis of double optic neuritis, and the remark that both visual fields were lost. The right eye had been useless 36 years, and for a year there was mistiness in the left. Vision was then 3/60, now it was 6/18. To get at the main point of detachment, he trephined above the tendon of the external rectus, and pulled the eye well forward by a tenotomy hook under the external rectus. He cauterised through the sclera until the subretinal fluid escaped, and aspirated the rest with a lachrymal syringe. He then perforated the retina above and below. In the middle of January the field was quite full.

Mr. **Horsford** showed a case of buphthalmia with malformation of the iris, and the causation of the condition was discussed.

Dr. F. W. **Edridge-Green** gave a lantern demonstration on some primary facts of colour perception, and an interesting discussion eventuated in a resolution being passed, on the proposition of Mr. C. D. **Marshall**, that a Committee of the Society be appointed to go into the whole question of colour-blindness and the tests for its detection, and report to the Society. Mr. **Lang** seconded the proposition.

Mr. **Marshall** asserted that the present tests failed in many instances, and that Holmgren's test could not be relied upon.

Mr. J. F. **Cunningham** showed an orbital case for diagnosis. It was thought to be apical periostitis, or caries of the apex of the orbit, or an optic nerve tumour.

Mr. J. H. **Fisher** showed a patient with microphthalmos, and a case of fundus changes resulting from injury at birth. The second of these patients was born with great difficulty, and there was a huge hæmatoma of the left frontal region, and soft tissues in the right temple and orbit were much damaged and lacerated by forceps. Possibly the optic nerve was damaged, and there was hæmorrhage from the lacerated vessels into the hyaloid canal, and that this formed the basis for the connective tissue organisation. He did not think there was any shrinking of the globe.

Mr. **BARDSLEY** showed a case of retinitis proliferans. A large bundle of connective tissue came forward into the vitreous. He regarded it as congenital, as there was a large detachment of the retina, and only a very small field. There was no history of injury, either at birth or since, but the eye had been defective as long as the parents could remember.

Mr. C. **WRAY** showed a case of follicular conjunctivitis, which he considered to be perfectly curable. It was contagious, and among 1,400 children in the Croydon schools, there were 12 cases of the condition.

Mr. **PARSONS** showed a patient the subject of a condition which he thought was probably metastatic neuro-retinitis. A woman had a glistening mass of exudate over the left disc, with considerable swelling, and some hæmorrhages on the disc. Then she suddenly lost the sight of that eye. The exudate diminished, leaving a glistening white star resembling that seen in albuminuric retinitis. She had no albuminuria.

CENTRAL MIDWIVES BOARD.

MEETING HELD THURSDAY, FEBRUARY 13TH, 1908.

Dr. CHAMPNEYS in the Chair.

THERE were present Dr. Stanley Atkinson, Mr. Fordham, Mrs. Latter, Miss Paget, Miss Wilson, and Mr. Parker Young. Mr. Bertram, the solicitor, also attended.

The correspondence included a letter from the Registrar of the Royal College of Physicians informing the Board that Dr. Champneys had been unanimously re-elected the representative of the College on the Board for the year ensuing April 1st next; also a letter from Miss E. M. Wright, of Leeds, informing the Board of the death of her father, Mr. C. I. Wright, one of the Board's Examiners for the Newcastle-on-Tyne centre. It was agreed that the Chairman should write, on behalf of the Board, a formal letter of regret. Dr. Donald, of Manchester, had written resigning his post as Examiner at that centre, as he could not spare the time for it. The Chairman was in receipt of a letter from Dr. Hellier, of Leeds, respecting his willingness to accept a post as Examiner, and it was accordingly agreed that he should be appointed to the vacancy at Newcastle-on-Tyne, in place of the late Dr. Wright.

The report of the Penal Cases Committee showed that various local supervising authorities had, at the request of the Board, sent in reports on the conduct of midwives previously censured or cautioned. About half of these reports were satisfactory. In the case of Mary Bent, against whom sundry indefinite charges had been made, it was agreed that the County Medical Officer for Lancashire be informed that the Board is extremely anxious to deal with drunkenness and other serious offences in midwives, but in the present case the local supervising authority have not found a *primâ facie* case, nor have they produced any direct evidence. The Chairman added that they could not censure a woman upon hearsay.

The Committee had prepared a list of 27 women to be cited to appear before the Board, which will hold a penal sitting on March 26th and 27th, to hear their cases.

The Standing Committee reported that a letter from the Clerk of the Council transmitting a copy of a letter from the Local Government Board enclosing a letter from the Executive Committee of the Rural Midwives' Association in regard to the question of the training of midwives, and the possibility of the grant of State aid in respect thereof, had been further considered.

A letter from the Clerk of the Council transmitting a copy of a memorandum addressed to the Secretary of State for the Home Department by Canon Dobell on the subject of the supply of midwives in rural districts, was further considered at the same time. A reply had been drafted by the Chairman, which raised some lengthy discussion. It was Dr. Champneys' view that the present impasse, caused by the lack of provision for the payment of medical men called in to midwives' cases, should be clearly represented to the Privy Council. Mr. Parkes Young wholly agreed, and considered that the Government was greatly to blame for neglecting to provide for this difficulty. The law obliged the midwife to summon medical aid in abnormal cases, and in a great number of cases—some of which were quoted at the meeting—medical aid was not forthcoming, as the doctors refused to answer the summons. It had been evident that for some time past there had been a general condition of friction between medical men and widwives, and the Chairman said he was not at all proud of a great number of his fellow members in the medical profession in their attitude towards midwives. It was neither humane nor national. After all, the first and most serious thing to be considered was the lives of our mothers and infants. After some amendments had been discussed, it was agreed that the reply should be sent to the Privy Council, and should be entered in full on the minutes of the Board.

A letter from Miss B. M. Worrall, Hon. Secretary of the Midwives Defence Association, as to the action of the local supervising authority for the County of London in regard to Rule E. 26, was further considered.

Memorials on the same subject from the Midwives' Institute, and from the Committees of the British Lying-in Hospital, the City of London Lying-in Hospital, the General Lying-in Hospital, and Queen Charlotte's Lying-in Hospital were considered at the same time; also a letter on the same subject from Dr. H. Scurfield, Medical Officer of Health for Sheffield.

The Board agreed that the Privy Council be asked to approve the addition of the following words to Rule E. 26:—

"Provided that a midwife whose name has been admitted to the roll in virtue of having passed the examination of the Central Midwives Board, or in virtue of a qualification under Section 2 of the Midwives Act, 1902, acquired by passing an examination in midwifery, may add the words 'by examination' after the words 'certificated midwife.'"

Letters were read from the Master and the Hon. Secretary of the Coombe Hospital, Dublin, submitting for the observations of the Board certain rules and regulations adopted by the Board of the hospital with respect to the training of pupil midwives.

The recommendation of the Committee was adopted —(*a*) That the Board of the Coombe Hospital be referred to the public Press for the results of the Board's examinations; (*b*) that, subject to the foregoing, the Board express general approval of the rules.

A letter had been received from a registered medical practitioner complaining of the conduct of a certified midwife, but the Board replied that the midwife did not appear to have infringed any of the rules.

The next meeting was fixed for March 19th, at 2.45 p.m.

CORRESPONDENCE

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Feb. 16th, 1908.

AMENORRHŒA OF LACTATION.

IF opinions touching the influence of menstruation on the secretion of milk and on the infant vary considerably, the majority of authors, at least, are agreed in considering amenorrhœa of lactation as the most natural, most frequent physiological law. Statistics, however, published within the last few years, seem to affirm that half of the women menstruate during nursing. In presence of this proportion, one might ask if a law presenting so many exceptions could be in reality a law, or if the law itself should not, on the contrary, be considered as an exception. Some years ago Gilliet, basing his opinion on the fact that he found that the nurses who menstruated during lactation were those who seemed to enjoy the best health, affirmed that amenorrhœa was the exception, and the return of the menses a normal and physiological fact. Essen-Muller and Gallard went so far as to suggest that in the interest of the infant nurses who menstruated regularly should be preferred.

Jacob established statistics to prove that the frequency of cases of menstruation diminished with the number of periods of lactation, and that amenorrhœa was the rule after the third period; but other statistics published by Hell and Ponsoyve would seem to show that amenorrhœa was only absolute after the fifth period of nursing.

This decrease in frequency is both interesting and significant. It is generally admitted that the multipara realises the most perfect type of nurse. Consequently the best nurse is the woman in whom amenorrhœa is the rule.

Tuberculous Cystitis.

Tuberculous cystitis requires prompt treatment on account of its gravity. Medical treatment should be first tried and addressed to the tuberculous diathesis—country air, rest, cod-liver oil, creosote, cacodylate of soda:—

Creosote, 1 drop.
Iodoform, 1-3rd gr.
Arseniate of soda, 1-50th gr.
Ext. of opium, 1-5th gr.
For one pill. Three daily.

As local treatment, instillations of iodoform, 5 per cent.; guaiacol, 1—20; corrosive sublimate, 1—5,000 to 1—1,000; which Guyon considers the best treatment of tuberculous cystitis. Nitrate of silver should not be employed in the first stage of the disease, as it might provoke congestion of mucous membrane, and even hæmaturia. But in the second stage, or that of secondary infection, instillation of a solution of nitrate of silver gives, according to Le Fur, excellent results. Irrigation of the bladder is always counter-indicated on account of the extreme sensitiveness of the mucous membrane. When the general and local treatment fail, recourse might be had to surgical treatment. The bladder will be incised in the supra-pubic region, and the granulations removed by the curette and the superficial ulcerations cauterised with the thermo-cautery.

In cases where the tuberculous ulcerations are consecutive to tuberculosis of a kidney, the removal of this organ completely cured the vesical disease, proving the intimate relation between renal and vesical tuberculosis.

Treatment of Vomiting.

Hydrochlorate of cocain }
Hydrochlorate of morphia, } āā ½ gr.
Lime water, 4 oz.
A tablespoonful every hour.

Or

Antipyrine, 30 gr.
Hydroch. of cocain, 1 gr.
Syrup of orange, 6 oz.

Tincture of iodine is frequently used in the vomiting of pregnancy.

Tincture of iodine, }
Chloroform, } āā 1 dr.
Five drops every half hour, up to 15 drops.

It can be associated with spirits of chloroform.

Tincture of iodine, 30 drops.
Spirits of chloroform, 1 dr.
Water, 4 oz.

In cancer or ulcer of the stomach, vomiting is frequent and provoked by the pain produced by the contact of the food with the ulcerated mucous membrane.

Rest in such cases is of the first necessity, no solid food being allowed, while alkalines in large doses will allay the pain.

Bicarb. of soda, 15 gr.
Calcined magnesia, 30 gr.
Prepared chalk, 10 gr.
Sub-nitrate of bismuth, 10 gr.
Lactose, 15 gr.
Codeine, 1-5 gr.
For one powder; two or three daily

Periodic vomiting coming on suddenly without any apparent cause is best treated by lemonade, bromides, belladona, opium, valerian, and revulsion in the form of the icebag to the pit of the stomach, mustard, and blisters.

An enema of a quart of physiological serum repeated twice or three times daily frequently arrests the vomiting of pregnancy.

GERMANY.

Berlin, Feb. 16th, 1908.

At the meeting of the Medinische Gesellschaft, Hr. Immelmann stated that he was in a position to confirm statements put forward by some observers that after RÖNTGEN ILLUMINATION the mucous secretion in cases of bronchitis became thinner. He had therefore made use of the X-rays in cases of chronic bronchitis, in both children and adults, and those who suffered from asthmatic troubles. Improvement had taken place very quickly, after even one or two sittings. He had not been able to make use of the treatment in acute cases.

Hr. Levy-Dorn had also seen improvement in such cases, but not in all. He attributed the effect to suggestion. He had put the apparatus in action without submitting the patients to the rays. In three cases this had no effect, and then the rays were actually applied. Improvement took place in one of the cases, but it was a question whether the strengthening of the suggestion did not play a part.

Hr. L. Casper spoke on RECURRENCES OF PAPILLOMA OF THE BLADDER

His remarks were based on nine cases, some of them his own; others were cases operated on by other surgeons. In all these tumours no malignant constituents were found, but it must not be concluded from this that no malignant germs were present. As all the tumours were operated on long before, some of them years, even, they were not to be looked on as malignant. Taken strictly, they were not local recurrences, as they did not occupy the site of the original tumour, they were not in their cicatrices, but elsewhere. They grew rather rapidly, in some months, and sprang up in a fungus-like manner from the whole interior of the bladder, so that the whole of this underwent papillomatous degeneration. From this behaviour it was a natural thought that there was some connection between the operation (sectio alta, which was the operation made use of in all the cases), and the rapid growth of the recurrent disease.

Amongst the 92 papillomata he had seen there were many muliple tumours, but never such extensive growths as after sectio alta. This confirmed him in his supposition.

That anything was left behind at the operation was excluded by the names of the operators. Transmission of the papilloma to the healthy mucous membrane was more likely, analogous to the experimental observation that warts were transmitted to healthy surfaces from other warts through inoculation with some irritating material. But this assumption was as unsafe as that which attributed the recurrence to vestiges of malignant disease left behind at the first operation. That a benign tumour could occasionally set up metastases could not be denied altogether, although it was a rare occurrence, and contradicted our ideas of the benignancy of tumours. "Metaplasation" of benign tumours was more readily conceived when they had a malignant germ in their deeper parts, and this was rendered mobile by the operation.

In the speaker's opinion the sectio alta was only to be employed when unconditionally called for, as experience taught that papillomata could remain in the bladder for 20 years, that their presence was not a matter of indifference, however, numerous examples showed, hæmorrhage, limitation of space, infection of the bladder, and malignant metaplasias were the dangers that threatened the patient suffering from papilloma of the bladder. It was therefore not possible simply to leave every papilloma to itself. Nitze had shown the proper way of removing them. This consisted in their intravesical removal, which the speaker reinforced by the injection of a strong solution of resorcin into the bases of the growths and their immediate neighbourhood. He had treated 65 cases in this way. There were recurrences—he had observed them 16 times—but they were never so extensive as after the sectio alta.

If the tumours had a very broad base, there was nothing for it but the high operation, with subsequent resorcin treatment. But the operation must be reserved for the exceptions. To get at the exceptional cases early diagnosis was necessary. When bleeding from an uncertain source took place from the bladder, therefore, the cystoscope should be used at once. The danger of hæmorrhage in intravesical removals was but slight. One way of seeing whether the tumour was malignant or not was to lift up the tumour with a loop under the guidance of the cystoscope; if the surrounding part of the bladder wall was not infiltrated it was shiny and translucent; if so, it was clouded and indurated.

Hr. J. Israel agreed, on the whole, with the speaker, but demanded more statistics before he would reject the high operation. Recurrences always took place when at the operation very small papillomata were seen, sometimes only with a lateral light, and after close looking for. These might possibly be excited to more rapid growth after operation. Some observations had taught him that the connection between papilloma and malignant disease was very close, although papillomata must undoubtedly be reckoned as benign. Twice in cases of cancer of the kidney he had seen papilloma at the openings of the ureters. One patient with papilloma of the pelvis of the kidney came back a year later with papilloma of the bladder, but died a short time afterwards from carcinomatous metastases in the internal organs.

He would operate intravesically if the tumour could be easily reached, and was not too large, otherwise he would remove by the high operation.

AUSTRIA.

Vienna, Feb. 16th, 1908.

SYPHILIS.

AT the Gesellschaft, Menzel presented a patient with a primary sore in the left nasal cavity, which had existed four weeks. Associated with this was the maculose exanthemata and multiple swollen glands. No other primary sore could be discovered over the body. The bacilli spirochæta were found in number in a small portion scratched off the sore. The virus seems to have been conveyed by the finger boring in the nose.

Ehrmann said he had several of the cases where the initial sclerosis or chancre commenced in the nose, but all of them ended in severe syphilis of the brain. Chiari thought the initial sclerosis was more common in the pharynx.

Lang said he had frequently met with primary sores on the head. He had also one on the lower jaw from the extraction of a tooth by which the virus had been conveyed. This case finally ended in dementia two years after the infection. He thought these cases had the nerves infected that carried the disease more readily to the higher centres. The hæmogenic theory was not excluded even in these cases, but the results seem to be more virulent in these cases than in those regularly infected about the genitals.

Nobl could not admit that these primary sores were different on the head and face from the extra-genital. It was true that fewer glands were affected, and that the virus would pass directly into the membranes and centres of the brain more readily; but if this were so we should have a larger number of such deaths, as a very large number of these cases are to be met with in everyday practice. He thought the subject was worth pursuing further, but nothing definite could be established with our present knowledge of the disease.

RUPTURE OF INTESTINES.

Föderl presented a case on which he had operated for a suspected rupture. The young man had received a kick from a horse, but the symptoms were not of such a nature as to convince the attendant that a rupture had taken place. It was decided to operate, and a rent in the small intestine discovered. He appealed to his colleagues, from this example, never to hesitate to operate where any suspicion remained after an injury to the abdomen of this kind. The only symptoms in this case were pain and tense contractions of the musculi recti.

As a contrast, he brought forward another case of perforation from peritonitis arising in the first place from an ulcer of the stomach. After describing his method of operation and the happy result, he said the mortality average was very high, being 66 per cent. The results are less affected by the method than the condition of the patient, the intensity of the peritonitis, and the extent of the operation. The virulence of the germ will greatly influence the prognosis. Eiselsberg's maxim of strengthening the patient is a good one, but how is this to be accomplished when the lesion is in the very organ that provides the strength. Lorenz prefers a gastrostomy fistula in the first place, and feed below the ulcer, or perform a jejunostomy with the ulcer after Eiselsberg's method. In the case brought forward both of these methods were impracticable. After opening the stomach, a long tube was inserted into the duodenum, and the patient fed for some time in this way till the strength recovered.

ACNE NECROTICA.

Spiegler showed a patient on whose face were large cicatrices, some white and smooth, others red or darkly pigmented. The disease seemed to be of a chronic nature, and belonged to the class of acne necrotica. Sulphur preparations seem to give the best results.

CEREBRO-SPINALIS EPIDEMICA.

Alt read a paper on meningitis cerebro-spinalis, which had become epidemic this winter, and had produced a considerable amount of permanent deafness owing to the purulent inflammation. He has had 50 cases where the auditory organs had been completely or partially destroyed. He showed microscopic preparations to demonstrate the changes, and agreed with Trolstch that the purpulent infiltration of the ependyma of the fourth ventricle, where the acoustic nerve is embedded, was the cause of the permanent deafness. He affirmed that the deafness was sometimes the first symptom, the facial nerve from its anatomical relations is little affected as it is more influenced by the local pressure. The vestibular nerve and its terminal branches suffer most, and hence the unsteady gait of the patient during the first week of the disease. Gradually the patient learns to steady himself by the other senses, but the younger the patient the longer the co-ordinating disturbance lasts. In young children, more than a year elapses before the child can walk steady. In older persons six months suffice, but it is difficult to account for the severity in some cases where the physical signs are but trifling, while in others the symptoms may be very severe, and little or no disturbance in co-ordination or hearing. The best form of treatment is large doses of iodide.

JAMAICA.

Kingstown, Jan. 1908.

THE latitude and longitude of Jamaica are still the same, and the climate has not changed more than that of other parts of the world are said to have changed; and yet this island, once looked upon as the graveyard of every European who landed on its shores, the home of the terrible "Yellow Jack," has become the health resort of thousands of Americans and others who annually visit it in the pursuit of health, or to escape the rigours or inconveniences of their own countries. Most of the writers on this really beautiful island, "the Queen of the Antilles," as it has been justly called, have contented themselves in describing the beauties of the island and the charms of its varied climates. I write "varied climates," for such, indeed, is the case; but these writers have never attempted to explain, so far as I have seen, the reason why Jamaica has been discovered to possess such health-giving powers. Before, however, attempting to advance a reason for this change, I must say a few words on the "varied climates" of the island, for this is a most important factor for those seeking the island in pursuit of health. From the torrid heat of the lowlands to the cool and bracing air of the Blue Mountains, whose highest peak reaches over 7,000 ft. above the sea, there is a constant change of climate. On the slopes of the mountains close to the sea one gets the sea and land breezes—the former known as "The Doctor." In the central parts of the island among the mountains there is a climate at once delightful and exhilarating. All that the visitor has to do is not to expose himself to the direct rays of the sun in the hottest part of the day, and to avoid being out as much as possible during the night, so as to escape the heavy dews, which, while they encourage the luxuriant tropical vegetation, are also the producers of rheumatic and catarrhal affections. These precautions being adopted, and another to which I shall now draw attention, will, I hope, show that there is no reason why Jamaica and the other West Indian islands should not be as healthful places of residence as any other parts of the world.

To describe the other point to which reference has been made, I must have recourse to the "Journal" of Lady Nugent, whose husband was once Governor of the Island. The "Journal" was written just a hundred years ago, and although it lacks the charm of those interesting character sketches which renders the reading of Pepys' and other diarists so delightful, it yet contains a very good account of the manners and customs of the people at the time it was written. From her account of the breakfasts and dinners in vogue at the time, it cannot be doubted that the excessive eating and drinking then indulged in were responsible for the sick and terrible death rates of the period. I cannot do better than give an account of a dinner in Lady Nugent's own words:—"Our dinner, at 6, was really so profuse that it is worth describing. The first course was entirely of fish, excepting jerked hog, in the centre, which is a way of dressing it by the Maroons. There was also a black crab pepper-pot, for which I asked the recipe. It is as follows:—A capon stewed down, a large piece of beef and another of ham, also stewed to a jelly; then six dozen of land crabs, picked fine, with their eggs and fat, onions, peppers, ochra, sweet herbs, and other vegetables of the country, cut small; and this, well stewed, makes black crab pepper-pot. The second course was of turtle, mutton, beef, turkey, goose, ducks, chickens, capons, ham, tongue, crab patties, etc., etc., etc. The third course was composed of sweets and fruits of all kinds. I was really sicker than usual at seeing such a profusion of eatables, and rejoiced to get to my own room, and, after my usual levee of black and brown ladies, to go to bed." Further on she says:—"I don't wonder now at the fever the people suffer from here—such eating and drinking I never saw; such loads of all sorts of high, rich, and seasoned things, and really gallons of wine and mixed liquors as they drink! I observed some of the party to-day eat of late breakfasts as if they had never eaten before—a dish of tea, another of coffee, a bumper of claret, another large one of hock-negus; then Madeira, sangaree, hot and cold meat, stews and fries; hot and cold fish, pickled and plain; peppers, ginger sweetmeats, acid fruit. sweet jellies—in short, it was all as astonishing as it was disgusting." "Mr. M.'s delight is to stuff his guests, and I should think it would be quite a triumph to him to hear of a fever or apoplexy, in consequence of his good cheer."

Apropos of the drinking habits of the times, I recently expressed surprise to a lady from Barbadoes at the size of the dining and drawing-rooms, and fewness of bedrooms in Jamaica and in the other islands. "Oh," she said, "bedrooms were not necessary, as the gentlemen were supposed to sleep under the tables." No wonder, with all this feasting, that estates bringing in a yearly income of £30,000 were heavily mortgaged, and that the death-rate was proportionally large. The immorality of the period, where one owner of several estates had a large coloured family on each of them, must also be taken into account. A more rational mode of living has therefore been the chief factor in the improved healthfulness of Jamaica and in human longevity.

The returns of the Registrar-General show that there are as many old people in the island as in supposed more favoured countries. For the year ending March, 1906, there were 187 deaths registered of people of 95 years of age and upwards. The one exception to this improved longevity is to be found in the infant mortality, but this is not the effect of climate so much as morality. With an illegitimate birth-rate of 65.2 per cent., it is not surprising that the death-rate of children under one year was 29.2 per cent., and 44.4 per cent. under five years. This is an important fact—that the death-rate of the parish of Manchester is 8.65 per cent. for legitimate, and 18.23 for illegitimate children, and this condition of things holds good for the other parishes of the island. Under the present conditions it seems almost impossible to prevent this fearful mortality among the negro races. Few of these people, comparatively speaking, marry till they have a family of groomsmen and bridesmaids to take part in the marriage ceremony of their parents. It is no uncommon thing to come across a woman who has had children by other men married to a man by whom she has had children before they were married. I was once present when an infant about a year old was shown to a medical man who had been for some years in practice in the island. The child had an enormous tense belly, swollen legs, with large blebs on the legs and instep. I asked what was the matter. "Worms," was the reply. A powder containing santonin and jalap was given, and the medical man informed me that the children crawl about the yards round the huts and eat all the garbage that comes in their way, and that from his experience worms were the cause and santonin the cure, and that in most cases it was always safe to administer a dose of that drug. Under such conditions is it wonderful that the infantile mortality is so terrible, nearly half of the children dying before they are five years old. It must not be thought that the authorities are blind to this fearful state of things, for the island spends £60,000 a year on so-called education, and it is to be hoped that eventually some good will result.

Very comfortable steamers are run by the Imperial Direct West India Mail Service between Bristol and Jamaica at stated periods and at moderate cost, whilst tourists going to the island who do not happen to have friends there can obtain comfortable accommodation at the Constant Spring Hotel.

LETTERS TO THE EDITOR.

CHRISTIAN SCIENCE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is unfortunately impossible to examine into the nature and claims of the cult which Mr. Dixon represents without wounding the susceptibilities of its ardent and sincere votaries of whom no doubt he is one; and it is remarkable that he does not recognise this, and refrain from charging his critics with "ostentatious discourtesy" when they employ the language alone fitted to meet the case. There exists neither cause nor place for spiteful feelings in this discussion. With the theology of Christian Science we have nothing to do, save in so far as it is bound up in the question of the cure of disease by miracle; and with this I dealt in my last letter. In common with all Christian Science literature Mr. Dixon's writings are so vague that it is difficult to discover any tangible statement to take hold of. He seems to imply that because our knowledge of Nature is limited, we are to disregard the solid facts of natural science, and look upon disease with eyes of mediæval mysticism. Our knowledge of the qualities of matter and force is incomplete, and our knowledge of pathology has its limitations, but this does not prevent us from recognising and dealing effectually with many of the gross concrete phenomena of disease. For example we cannot at present perhaps trace finally the primeval evolution of the itch insect or the tapeworm; but we know that we can by medical means destroy and expel these parasites from the system, and so put an end to the symptoms to which they give rise. We have proved our power here by experiment repeated ten thousand times with the same result. We call the knowledge gained by such experiment and observation, science. Itch insects and tapeworms are very tangible objects; but they are not really more tangible than the poisons which give origin to a vast number of diseases, although these poisons may not be demonstrable, except with the use of the microscope and by methods of minute investigation.

Many of the diseases to which these poisons give rise are amenable to medical treatment. We therefore do not believe "that disease can only be radically cured by Divine power casting out errors of human sense," "and that to trust implicitly in Divine power is to be cured of physical disease." This was the explanation of the claims of Christian Science given at the inquest this week by the practitioner in charge of the case. The treatment was daily prayer by the practitioner, and the patient was required to "put his trust in God." The efficacy of such treatment could be believed in only by those who, like this Christian Science practitioner, "had not studied medicine, and had never made any pretence to do so." Is it not evident that the wide acceptance of such teachings must lead to a vast increase in the amount of human pain and misery; and is it not the duty of the profession to strive to make plain to the public the real character of such anti-scientific and pernicious nonsense?

I am, Sir, yours truly,
HENRY SEWILL.

February 12th, 1908.

THE NATIONAL TELEPHONE COMPANY AND MEDICAL MEN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As you doubtless know, the National Telephone Company, whose monopoly will expire in two years, have lately issued a new scale of rates for their subscribers. I have heard two explanations offered for the changes they have made, one being that these changes are due to the Post Office authorities, the other that they are due to the desire of the company to acquire the last pound of flesh from their subscribers before finally leaving them. According to the new scale, there are two sets of rates which apply to subscribers in towns. The first applies to "business places and residences," and the second "to residences only." The most important feature of the first rate is that it grants 500 calls for a sum of £6 a year—that is to say, each call costs the subscriber a very small fraction under 3d. The most important feature of the second rate is that it grants an unlimited number of calls for £8 a year.

As you, Sir, also doubtless know, the existing rate up to the present time is an unlimited number of calls for £10 a year.

Now, at first sight, the new arrangement seems to offer an advantage to the medical subscriber; but, Sir—and it is to this point I wish to draw your attention—"doctors' and dentists' residences and premises will be connected at the rates for business purposes only." The result of this is that in future, instead of obtaining an unlimited number of calls for £10, the medical subscriber will receive 500 calls for £6, and for another £4 he can purchase about 1,300 more calls, so enabling him to telephone on an average five times daily.

I would further point out that up to a few years ago medical men on the staff of a hospital were given the special rate of £8 10s. a year for an unlimited number of calls.

I venture to think that such a course of action on the part of a large semi-public body such as the National Telephone Company is not only most unjust to medical men, but is degrading to the company itself as the holders of a great public trust. It is nothing short of scandalous that medical men and dentists should be selected out of the large body of professional men to be told that their residences are "places of business," and must be treated accordingly, and I cannot understand how some of the several bodies who are supposed to look after the interests of medical men have failed up to this to make a protest. In the next place, even assuming, which I do not for a moment consider justifiable, that medical men must submit to such treatment, and may not be allowed the lower rate given to what the company considers "residences," why should their rates be raised, and why should an unlimited service be changed into a fixed service, averaging only five calls daily?

I am afraid the answer is only too obvious—the company know that medical men cannot dispense with the telephone, and they think that the various medical bodies will not bother about interfering in the matter.

May I venture, Sir, to express the hope that in this respect they will be disappointed, and that a vigorous and concerted effort will be made to force the company to recognise that medical men's houses are private residences? If you, Sir, in your influential journal will ventilate the matter, I am most hopeful of success.

In conclusion, may I point out that the new rates are causing universal discontent, and that, as I understand, Parliament is to be asked to appoint a Commission to inquire into them. The time, therefore, is most opportune for prompt action.

I am, Sir, yours truly,
AN OWNER OF A PRIVATE RESIDENCE ALTHOUGH A DOCTOR.

MEDICAL REGISTRATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is very desirable that practitioners should not lose the privileges attaching to registration owing to their names ceasing to appear in the *Medical Register*.

It has been found, however, that many practitioners, not fully appreciating this, especially within a short time of qualifying and registering, fail to give to this office from time to time an address at which official communications will reach them, and they thus incur the risk of their names not being retained on the *Register*. In the interests, therefore, of the practitioners themselves the enclosed notice has been drawn up. I shall be happy to supply you with further copies if they will be of service.

I am, Sir, yours truly,
H. E. ALLEN,
Registrar.

General Council of Medical Education
and Registration of the United Kingdom,
299, Oxford Street, London, W.,
January 31st, 1908.

[The notice quotes the sections of the Medical Act, 1858, referring to the keeping of the Registrar of the Council informed of change of address. It is most important that medical men should bear them in mind.—ED.]

THE FACIAL MUSCLES IN ACHONDROPLASIA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. R. L. Jones, of the London Hospital Medical College, has very kindly sent me notes and careful measurements of the facial muscles in two achondroplasic fœtuses, and has compared his results with the condition found in a normal fœtus. His results do not bear out the suggestion made in my letter published last week—viz., that hypertrophy of the facial muscles may be a characteristic of achondroplasia. Mr. Jones' observations were made on specimens in the possession of Dr. Keith.

I am, Sir, yours truly,
A. FRANCIS DIXON.

Medical School, T.C.D., February 13th, 1908.

THE "TIMES" AND QUACK ADVERTISEMENTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—A leader on Saturday last in the *Times* contains the following passage:—"We must admit that the advertisement sheets of certain publications are continually made the vehicles of statements which can only be described as preposterous; and, frequently, as being false to the knowledge of those who make them. There are advertisers who undertake to make their customers shorter or taller, fatter or thinner, as they may desire, etc., etc."

Astonishing as it may seem it is evident that the editors of the *Times* are quite ignorant of the uses that are now being made of the advertising columns of their own paper. From day to day there are to be seen in the *Times* numbers of quack advertisements of the kind described in this leader. It is impossible they could find admission if the managers would ascertain their true character from one or other of the able medical writers, who, if not on the staff, are constant contributors of editorial matter. Further inquiry would surely convince the managers of the *Times* that the injury to the prestige of their great journal, caused by its descent from its former position of dominating superiority in every respect over all other papers, far outweighs the gain derivable from its present money-making methods. The managers of the *Times* have rendered it impossible for the editors to attack many of the most glaring abuses of the day without stultifying themselves, as on the present occasion, in a manner at once ludicrous and deplorable.

I am, Sir, yours truly,
AN OBSCURE PRACTITIONER.
February 17th, 1908.

OBITUARY.

GEORGE BRAIDE, M.R.C.S., L.R.C.P.

It is with great regret that we have to announce the death of Dr. George Braide, which took place at Warrington. He had not been quite well for some weeks, but the end came with painful suddenness. Dr. Braide was only 42 years of age, having been born in Liverpool on November 16th, 1865, his father, Mr. Edward Braide, at the time being chief clerk on the London and North-Western Railway at Liverpool. He studied for the medical profession at Owens College, and on obtaining his qualification was appointed to the Manchester Royal Infirmary, afterwards acting as *locum tenens* at Urmston. He went as a ship's doctor for several voyages out to India, finally commencing practice, some 16 or 17 years ago, in Warrington. He secured the appointment of medical officer to the union workhouse. Among other appointments he held was that of medical officer to the Blue Coat School, also of the Warrington district of the London and North-Western Railway Company, and of two or three leading firms and insurance companies. He was held in high repute by his medical *confrères*, by whom his death is extremely regretted. He had passed the chair of the Warrington Medico-Ethical Society, which includes practically all the doctors in the town and district in its membership. Dr. Braide had a host of friends in the town and district, and by these, apart from his many clients, who always had the greatest confidence in his skill and judgment, his loss will be greatly felt and sincerely mourned.

CHARLES ARTHUR AIKIN, F.R.C.S.

We regret to announce the death of Mr. Charles Arthur Aikin, F.R.C.S. He was the only son of Charles Rochemont Aikin, M.R.C.S., by a daughter of Gilbert Wakefield, the well-known scholar, and was born in London in 1821. He was educated at University College School and Guy's Hospital, and he became a qualified medical man on the eve of his 21st birthday. He settled in the district known as Tyburnia, and soon formed a large practice on the north side of the park, where he made many friends, who valued him, deservedly, both for his professional and his personal qualities. In 1858 the Royal College of Surgeons honoured him with its Fellowship. Mr. Aikin retired from practice at about the age of 70, and, after some years more in London, spent the last few years of his life at his sons' residence in North Wales, where he died on Tuesday the 11th inst. His widow and four of his six children survive him.

WILLIAM HENRY REAN, M.D., ST. AND.

We regret to record that Surgeon-General William Henry Rean died at his residence in Oxford Gardens, W., on February 6th, aged 81. He was one of the first pupils of Sir Isaac Pitman, and he used the then new system of shorthand when attending his hospital lectures. After qualifying, he was house surgeon at the Middlesex Hospital, and entered the East India Company's service by competition in 1853, in which year he went to India. In 1857 he served with the Madras Fusiliers in the attempted relief of Cawnpore, and was medical officer on board the small river steamer *Bramaputra*, which was despatched up-stream from Allahabad, and arrived at Cawnpore shortly after the massacre. After the Mutiny he served as senior medical officer in the Andaman Islands for nine years, which position he held when Lord Mayo was assassinated. Before he retired, in 1881, after 33 years' service in India, he was Deputy Surgeon-General at Kampti. In 20 years of retirement, in spite of his long and arduous services in the East, he enjoyed perfect health until December last, when he contracted the sudden illness which prevented him from joining the recent *reunion* of his comrades in the Albert Hall.

REVIEWS OF BOOKS.

FRENCH'S LABORATORY METHODS. (a)

We are glad to find that our prophesy has been fulfilled. We declared that French's "Laboratory Methods" would run through many editions. It is now, after the lapse of two years, in its second. This was only to be expected. The book, though written by one who is comparatively a junior in the profession, is the handiest guide to clinical methods with which we are acquainted. All others are too large and pretentious. The one before us contains all that the average student or practitioner requires for the needs of actual practice. The improvements in the present edition are evident. Much of the text is new, and many new methods have been introduced. A word of warning to the author may be necessary. We trust he will never be tempted to increase the bulk of the volume.

His chapters on the examination of the blood and of the stomach contents are the clearest and simplest expositions the reader can ever hope to meet with. The author's personal work in connection with the examination of the blood is well recognised, and he certainly writes very ably on this particular subject. Many of the illustrations in the book are new, and the coloured ones are specially noteworthy. The binding and also the paper used in the production of this edition are an improvement on the former one. The author and his publishers alike are to be congratulated on the appearance of the second edition of a guide to laboratory methods which is at once a model of neatness and of practical utility.

LIFE ASSURANCE AND GENERAL PRACTICE. (b)

There is at the present moment certainly room for a book dealing with the medical examination of life assurance candidates. The modern developments of life assurance have necessarily entailed changes in the medical aspects of lives, besides the greater experience now accumulated by medical officers to assurance companies and actuaries. The old elaborate forms are giving way to simpler and more practical ones, and the office which teases the life out of its candidates by irritating questions is likely to have fewer and fewer proposers. At the same time we cannot commend the departure of some offices in abrogating medical examination altogether, and applicants under such a scheme are not probably aware that, when their life value is guessed at the office must leave the margin of doubt in its favour. The object, then, of a modern company should be to devise a simple, straightforward scheme which, in the hands of reliable examiners, fixes on the important points. How far does the work before us help the medical practitioner to meet these conditions? On the whole, it is not pedantic and fussy, and that is a great point in its favour, but, on the other hand, it is a little thin and unsatisfying. There is not enough definite information in it to make a standard book, and its value lies more in suggestiveness than in actual pabulum. The difficult questions that one would like to see discussed are skimmed over, and though the author does not commit himself to rash statements, he seldom helps us by authoritative ones. The relation of alcohol to life assurance is talked round rather than tackled; heredity and gout the same. The chapter on syphilis is much better, and those on tuberculosis and the circulatory system are certainly helpful. Albuminuria, the *bête noire* of assurance work, really should have been treated fairly and squarely in a book dealing with this special class of work, and the methods and conditions necessary for exact diagnosis of the origin and significance discussed and described. We are disappointed, too, that so little information as to the assessment of faulty lives is given, and to find no real assurance questions, such as the differentiation of lives according to the suitability under the several tables, discussed. As a handbook to practitioners unaccustomed to this class of work it may be of value.

(a) "Medical Laboratory Methods and Tests." By Herbert French M.A., M.D.Oxon., F.R.C.P.Lond., Assistant Physician Guy's Hospital &c. Second Edition. Pp. viii, 168. With 29 coloured and 59 other illustrations. Crown 8vo. Leather, gilt top. Price 5s. net. London: Bailliere, Tindall and Cox. 1908.

(b) "Life Assurance and General Practice." By E. M. Brockbank, M.D (Vict..)., M.R.C.P., Hon. Assistant Physician, Royal Infirmary, Manchester. London: Henry Frowde and Hodder and Stoughton. 1908.

DISEASES OF THE GENITO-URINARY ORGANS AND THE KIDNEY. (*a*)

WE have perused the pages of this volume with very great pleasure and profit, as it gives a very concise idea of the various diseased conditions of the kidney and genito-urinary tract as studied by the general practitioner and surgeon in the present day. The work runs to 520 pages, with a very copious index, and the subjects treated are divided into thirty chapters, and also contains 292 well-executed illustrations. In the opening chapters much valuable information regarding the general examination of patients is given, as well as practical hints on the subject of endoscopy, cystoscopy, and catheterisation of the ureters. The writers state they do not profess that the book is complete, but it is the conjoint product and effort of a surgeon and a practising physician, and it is thus intended that equal attention should be devoted to both medical and surgical aspects of genito-urinary diseases. Anyone anxious to devote attention to this special branch of surgery will do well to purchase this work.

A MANUAL OF SURGERY. (*b*)

THE author states that this work has been prepared for the undergraduate whose crowded hours demand a manual stripped of verbiage and un-essentials, and for the medical practitioner who seeks a guide to present-day surgery. He further adds his chief desire has been to set down concisely and completely those facts which the student must know, and to make such suggestions in diagnosis and treatment as will best aid the physician in his daily practice, and the aim throughout has been to be brief and practical. The subjects are treated, as a rule, in a thoroughly practical manner, but owing to the anxiety to be brief, and to keep the size of the volume within reasonable dimensions, a few subjects get but a sketchy notice. The work is divided into 31 chapters, and the illustrations, numbering over 500, are very good. To students preparing for an examination this work would no doubt be found to be very useful, and all information given is quite up-to-date.

SQUINT AND OCULAR PARALYSIS. (*c*)

THIS book is the outcome of the author's experience extended over some years, and the attempt, as he tells us in the preface, "to bring into line and compare some of the best practical teaching of the English and foreign schools." Without going very deeply into the subject he nevertheless presents us with a concise and practical description of the various muscular defects of the eye, together with the treatment of the same. Upon the management of convergent strabismus, by orthoptic exercises, he has much to say which is to the point, and if operative treatment is required in children he holds that it is preferable to wait until they are nine or ten years of age. In the section devoted to ocular paralysis, the anatomy and physiology of the extrinsic muscles is discussed fully, and afterwards chapters follow "on general symptomatology of ocular paralysis," and the "etiology, prognosis, and treatment." Heterophoria and heterotropia are subsequently dealt with, and the work concludes with an appendix, descriptive of the use of Rémy's diploscope. The book is one which will be read with interest by all to whom the subject appeals.

MEDICAL JURISPRUDENCE. (*a*)

WE welcome the second edition of Dr. Fred. J. Smith's "Lectures on Medical Jurisprudence," and congratulate the author on having found an appreciative "public." Although in no sense a substitute for the ponderous tomes on the subject, this work will amply supply the ordinary student with all he needs before "facing the music" on the Embankment, and, moreover, he will find the instruction pleasantly conveyed in a chatty and taking manner. Three new lectures appear in this edition, "The Examination of the Person Alive and Dead," "Anæsthetics," and "Death Certification." The question of anæsthetics is much to the fore just now, and Dr. Smith is able to give some excellent suggestions to practitioners who have the misfortune to find themselves before the coroner. We regret that the author has not found room for a few "leading cases," but in a handbook of the dimensions of the one before us we can hardly expect it. It is a common-sense book written by a practical man.

LABORATORY NOTES.

BROMURAL.

MESSRS. KNOLL AND CO. are bringing forward a sedative and mild hypnotic in Bromural. This drug is a bromide of the Valerian group (monobromisovalerianyl-urea). It is obtained by combining urea with bromide of bromino-valerianyl, and stands in its action between the bromides and valerian preparations on the one side, and the hypnotics, such as trional and veronal on the other. Bromural exists in the form of white, almost tasteless, needle-like crystals, which are soluble in hot water, ether, alcohol and alkalies, but with difficulty in cold water. Its melting-point lies at 146° C. Experiments on animals have shown that with very large doses of Bromural it is possible to obtain even deep sleep-producing effects without in any way affecting either circulation or respiration. The sedative and hypnotic action is said to be due, not to the presence of bromine, for the latter does not become split off from it in the organism, but to the isopropyl group contained in the valerianic acid. The action of this group is further intensified by the binding up of the carboxyl group by means of urea and by the introduction of a halogen atom into the methylene group. Bromural is not to cause stupor, but dreamless sleep from which the patient awakes fresh and invigorated. All action by Bromural ceases after from three to five hours, probably on account of its rapid decomposition and elimination by the organism. Bromural is indicated in the difficulty of falling asleep which accompanies some of the milder forms of nervous disturbance, such as hysteria and neurasthenia, and cases where the alkaline bromides cannot be borne or where their action is not sufficiently powerful. It does not produce the desired effect in sleeplessness accompanying organic disease, conditions of worry and excitement occurring at night, hallucinations, and so on.

(*a*) "Diseases of the Genito-Urinary Organs and the Kidney." By Robert Holmes Greene, A.M., M.D., Professor of Genito-Urinary Surgery, Medical Department of Fordham University, &c., and Harlow Brooks, M.D., Assistant Professor of Pathological Anatomy, University and Bellevue Hospital Medical School, New York City. Pp. 536. 292 illustrations. Philadelphia and London: W. B. Saunders Company. 1907.

(*b*) "A Manual of Surgery for Students and Physicians." By Francis T. Stewart, M.D., Professor of Surgery, Philadelphia Polyclinic: Associate in Surgery, Jefferson Medical College, &c. Pp. 778, and 504 illustrations. London: Rebman, Ltd. 1907.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT PATHOLOGICAL LITERATURE.

Multiple Primary Carcinoma.—McConnell reports (*Journal of Medical Research*, July, 1907) a case which he regards as one of primary carcinoma occurring at several sites at the same time. The patient was an aged female, and, according to the clinical history, she developed simultaneously ulcers of the upper lip and of the wrist. Some months later a similar ulcer developed on the cheek. Death occurred, and at the autopsy it was established that the ulcers were epitheliomatous in nature, the structure being that of an ordinary epithelioma with plentiful cell-nests. At the autopsy also it was discovered that there were several ulcers in the stomach, while the gastric glands were enlarged, and tumours were present in the liver. The histology of this group of lesions presented some difficulty, and doubts existed as to whether the condition was one of sarcoma or of carcinoma. If the latter, was it primary in the stomach, or secondary in the tumour of the lip? The microscopic appearance, while not contradicting it, failed to give support to the last suggestion. No trace was found in the gastric or hepatic growths of squamous epithelial structure. There was no formation of nests, there were no epithelial pearls, and no horny degeneration was found. The author, therefore, inclines to the belief that the condition of the stomach was primary, and had no direct relation with the superficial tumours. He believes also that it was carcinomatous rather than sarcomatous in nature. It is interesting to note that the patient exhibited also a fibroid of the uterus. R.

Rhabdomyoma of the Heart.—Wolbach (*Journal of Medical Research*, July, 1907) adds a case of rhabdomyoma of the heart to the very small number of cases already recorded. This makes, according to the reporter, only the twelfth authentic case. These tumours are always congenital, and are associated with general mal-nutrition. The subject of the present report was a child of ten months. The heart was very large, and in the right ventricle, below the posterior segment of the pulmonary valve, was the tumour, spherical in shape, and 1.7 centimetres in diameter. It was attached to, or rather growing from, one of the papillary muscles. Histologically its structure was identical with that of other specimens described, the cells presenting the greatest variations in size, and many of them exhibiting marked vacuolation. This vacuolation is so extreme as to give the tumour a sponge-like appearance when seen under the low power. A very curious, if not unique condition, of the meninges of the brain and spinal cord was discovered. Scattered on the inside of the dura mater, particularly in the cervical cord, but occurring in other regions of the cord and also over the brain, were enormous numbers of small discrete nests of neuroglia tissue. They were quite separate from the cord, and the reporter does not believe that they originated therefrom. He can find no recorded instance of a similar condition. In many of the other cases of congenital rhabdomyoma there was present diffuse cerebral sclerosis; this was absent in the present case. The paper is enriched by excellent microphotographs, and the histology of the tumours is described in great detail. R.

Sarcoma of the Appendix.—Carwardine (*British Medical Journal*, December 21st, 1907) reports a case of sarcoma of the vermiform appendix, a condition of which he can only find two previous cases recorded. He can only find the histories of 42 instances of primary malignant disease of the appendix, and, of these, 37 were carcinoma. In the present case, at operation, the appendix was discovered to be some 3½ inches long, and as thick as one's thumb. It broke with a carrot-like fracture. Microscopically, it consisted of round cells, with little inter-cellular reticulum. The proof that the tumour was primary is hardly complete, as the patient died some nine months later with a large tumour of the ovary. R.

The Speed of Phagocytosis.—Walker (*Journal of Medical Research*, July, 1907) points out a source of error in the usual method of determining the opsonic index, which had not, we think, previously been noticed. In the technique used by Wright, and by most of those who follow him—and they are the majority of opsonic workers—equal proportions of bacteria, of washed leucocytes, and of blood serum, are mixed and incubated for a definite time—usually 15 or 20 minutes. The degree of phagocytosis is assumed to depend on the degree of sensitisation of the bacteria by the opsonins, and if the rate of sensitisation or opsonisation is slow, extending over the period of incubation allowed, then, with a thin suspension of bacteria, we might expect phagocytic indices proportional to the amount of opsonins present. On the other hand, if sensitisation takes place rapidly, and is completed within the first few minutes of the incubation period, the phagocytosis should be complete in all the preparations in the given time, and all the indices should be equal. Moreover, if too few bacteria are present to satisfy all the opsonins of the stronger serum, the weaker one being satisfied, then errors of all degrees should be possible. It was easy to show by experiment that sensitisation was completed very rapidly, and the author discovered that one minute gave as complete sensitisation as 20 minutes. He next investigated whether, if the bacterial suspension contained fewer germs than the opsonin of either serum was able to sensitise, the result would be that each serum would give the same index, bring suspensions of bacteria of graded strengths, and sera, of which one was a half-strength dilution of the other, he found that the phagocytic average increased with each serum equally up to a certain point in the graded series of emulsion, the average being proportional to the number of bacteria in the emulsion. Beyond that point, and presumably where the quantity of bacteria was as great as the opsonins could sensitise, the phagocytic averages were in their proper proportion of 2 to 1. Walker has therefore established that it is necessary to make sure that the bacterial emulsion is sufficiently dense to exhaust the opsonins, or the result will be entirely untrustworthy. R.

The Origin of Rodent Ulcer.—Noon (*Journal of Pathology and Bacteriology*, October, 1907) publishes some observations on the site of origin of rodent ulcer. For long there has been debate as to the nature of rodent ulcer, and the cells from which it originates. Some regard it as a tumour of the hair-follicle, others as a tumour of the sweat glands; while another hypothesis, ignored by Noon, is that it is an endothelioma. Noon, in some of his specimens, was able to trace a definite connection of the tumour with the Malpighian layer of the epidermis, near the neck of the hair-follicle, and with the reflection of this layer which constitutes the outer root sheath. In other cases, however, of clinical rodent ulcer he found an intimate connection with the sweat glands; and it was hard to avoid the conclusion that he was dealing with a carcinoma of the sweat glands. He suggests, therefore, that there may be two pathological entities—epithelioma of the Malpighian layer and carcinoma of the sweat glands—which are grouped together under the clinical term—rodent ulcer. The paper is well illustrated, and the histological descriptions are clear.

Polyarthritis Acuta Nodosa.—Dickson (*Journal of Pathology and Bacteriology*, October, 1907) reports a case of this very rare disease, with a study of the reported cases. The disease is characterised by wasting illness of a couple of months' duration, nervous excitation, followed by semi-coma, being a marked symptom. Pathologically, the typical lesion is a nodule growing on the coats of the small and medium-sized arteries throughout the body. These nodules are due to localised inflammatory, destructive, and proliferative changes in the vessel wall, the most important change being the complete destruction of small areas of the muscular coat. Nothing is known of the cause, but the presumption is in favour of its being a toxin of some sort. Dickson can find no previous case recorded in Great Britain. R.

Secretin and Pro-Secretin in Diabetes.—Bainbridge and Beddard report the result of their observations on diabetic patients (*Guy's Hosp. Reports*, Vol. LXI., p. 161). These observations were directed towards the elucidation of two points:—(1) To determine whether pro-secretin was deficient in the duodenal mucous membrane of patients who died from diabetes, and (2) to determine the influence of secretin administered as a drug in the glycosuria of diabetes. The first series of experiments were carried out with an acid extract of the duodenal mucous membrane of six diabetics, and of nine patients who died from other diseases, the extract being tested by intravenous injection into anæsthetised cats and dogs. The result was most remarkable, as it showed that in five of the diabetics pro-secretin was either absent or present in very small quantities, as compared with the amount present in non-diabetic cases. Pro-secretin was, however, present in normal quantity in one case, and also in a cat a fortnight after excision of the pancreas. That its absence in the five cases was not due merely to acid intoxication seems proved by the fact that artificial acidæmia in a rabbit did not diminish the pro-secretin at all. The second point was investigated by careful observation of the carbohydrate metabolism of three diabetic patients treated by secretin. The drug was given at first subcutaneously, and later by the mouth, and the conclusion arrived at was that the administration of secretin by the mouth had no influence whatever upon the output of sugar in the urine. As, however, Starling has shown that secretin is not absorbed when introduced into the alimentary canal of animals, the writers think that further observations on its subcutaneous administration are desirable. The objection, however, to these is that they are attended by considerable pain. They believe that the results previously reported by Moore were to be attributed more to dieting than to drugs. The same authors have also investigated the livers, blood and muscles of diabetic patients and of depancreatised cats to ascertain whether they possess the normal diastatic ferments, and have found them present in every case. M.

Tetany Associated with Dilatation of the Large Intestine in Children.—Langmead (*Trans. Clin. Soc.*, Vol. XL., page 67) calls attention to a clinical syndrome met with in children, and consisting of the following group of symptoms:—(1) Obstinate relapsing tetany; (2) abdominal distension; (3) offensive, unhealthy motions; (4) a dilated large intestine, as verified by post-mortem, or by laparotomy. He reports four such cases, in two of which the dilatation of the large intestine was general, in one it was limited to the sigmoid flexure, and in the fourth to the transverse colon. He considers that these cases throw some light on the general etiology of tetany, as in each of them considerable toxæmia must have been present, due to absorption from the fermenting fæcal material. Improvement resulted when the bowel was washed out, and also when thyroid gland was administered by the mouth. This last fact suggests that perhaps normally intestinal toxins are absorbed and then neutralised by the thyroid or para-thyroid secretion, and that it is only when they are generated in great abundance that this neutralisation cannot take place, and that tetany results. As a contributing factor, also, there was present in the four cases prolonged malnutrition, a condition which would obviously render the body more susceptible to the influence of a circulatory toxin. M.

Relation of the Pancreas to Diabetes.—Thoinet and Delamere have investigated the pancreas in seven cases of diabetes, with the object of determining which of the current theories deserves most credence (*Arch. de Méd. Expérim. et d'Anat. Pathol.*, 1907, No. 2). These theories are—(1) That diabetes is due to a primary or secondary insufficiency of the cell-islets of Langerhans; (2) that it results from acinar insufficiency. The authors state that they have found most varied changes in the structure of the pancreas, which they group as follows—(1) Interstitial cirrhosis, which spared equally the acini and the cell-islets; (2) interstitial cirrhosis, which involved equally the acini and the islets; (3) in no case was there any special destruction of Langerhans' cells; (4) in some cases both interstitial overgrowth and acinar destruction were present, with special escape of Langerhans' cells. As a result of these observations the writers conclude that it is impossible at present to attribute diabetes to the destruction of any special part of the pancreas. M.

The Relation of the Kidneys to Metabolism.—Bainbridge and Beddard have repeated the experiments of Rose Bradford on the kidneys with the object of determining what effect these organs exert on general metabolism, and more particularly to ascertain whether Bradford's conclusion that they furnished an internal secretion was justified or not (*Guy's Hosp. Reports*, Vol. LXI., p. 149). The experiments were carried out on cats, three of which survived excision of one entire kidney and about two-thirds of the other for several days. Their conclusions are as follows:—(1) Removal of three-quarters or more of the total kidney weight in cats is followed by loss of appetite, wasting and death within a few days or weeks; (2) in such cats an increased output of nitrogen is not of constant occurrence, but is found only in animals that have lost 22 per cent. or more of their initial body weight; (3) this increase of nitrogen output is therefore to be regarded merely as the result of inanition, and is of the same nature as that observed in starving animals; (4) after removal of part of one kidney, and subsequent removal of the opposite kidney, cats are still able to pass a concentrated urine, and the amount of the urine is not necessarily increased beyond the normal. M.

MEDICAL NEWS IN BRIEF.

Visit of the British Association to Dublin.

THE following have been elected by the Council of the British Association to be Presidents of Sections at the meeting of the British Association which is to be held in Dublin in September under the presidency of Mr. Francis Darwin, F.R.S.:—

Section A (Mathematical and Physical Science).—Dr. W. N. Shaw, Director of the Meteorological Office. Section B (Chemistry).—Prof. F. S. Kipping, Nottingham. Section C (Geology).—Prof. J. Joly, Dublin. Section D (Zoology).—Dr. S. F. Harmer, Cambridge. Section E (Geography).—Major E. H. Hills. Section F (Economic Science and Statistics).—Lord Brassey. Section G (Engineering).—Mr. Dugald Clerk. Section H (Anthropology).—Prof. W. Ridgeway, Cambridge. Section I (Physiology).—Dr. John Scott Haldane, Oxford. Section K (Botany).—Dr. F. F. Blackman, Leeds. Section L (Educational Science).—Prof. L. C. Miall, Leeds.

The University of Sheffield.

THE Council of the University have appointed Mr. John L. Annan, M.B., Ch.B.Edin., to the post of Demonstrator in Anatomy. Mr. Annan is at present Demonstrator of Anatomy in the University of Edinburgh, and House Physician in the skin wards of the Edinburgh Royal Infirmary; and to the newly-instituted Clinical Tutorships:—Mr. Miles H. Phillips, M.B., B.S.Lond., F.R.C.S.Eng., Obstetrics and Gynæcology; Mr. Graham Simpson, F.R.C.S.Eng., Surgery; Mr. A. E. Barnes, M.B.Lond., M.R.C.P., Medicine. Mr. Phillips is the Assistant Medical Officer at the Jessop Hospital for Women, and Mr. Simpson Assistant Surgeon at the Sheffield Royal Hospital. Mr. Barnes holds a British Medical Association Research Scholarship, and is at present engaged in research in the Pathological Laboratory of the University.

A Baron M.D.

BARON BRUNO VON HOHNFELDT, M.D., alias Chris. J. Hughes, aged 59, described as a doctor of medicine, living at Star Street, Edgware Road, was charged on a warrant, before Mr. Plowden, with attempting to obtain charitable contributions from Mr. Arthur F. G. Leveson-Gower, of 31 Gloucester Place, Portman Square, with intent to defraud.

The accused, a well-dressed man of gentlemanly appearance, wore a dark, heavy moustache, and carried a silk hat and a pair of kid gloves.

Mr. Plowden inquired if he really were a baron, and he replied that he was.

Detective-Sergeant Draper proved the arrest of the prisoner in Star Street, and stated that when told the charge, he said he had done nothing for which to be arrested.

Mr. Arthur Leveson-Gower stated that in December last he received a letter from a "Mr. Hughes," apparently a medical man, saying that he had in a hospital he was attending a patient named Mr. Edmund Banbury, who had been with him (Mr. Leveson-Gower) at Christ Church, Oxford, and had fallen on bad times. The writer than went on to suggest that the witness should help him in his charitable efforts on Mr. Banbury's behalf. Mr. Leveson-Gower said he consulted a friend about the letter, and subsequently saw Mr. Banbury himself, with the result that a warrant was obtained for the prisoner's arrest. Mr. Banbury, he added, was an acquaintance of his at Christ Church.

Mr. Edmund Banbury, who resides at 16 Hans Place, S.W., was then called, and disclaimed all knowledge of the prisoner.

Other evidence was given that the prisoner arranged for letters to be received on his behalf at a shop in Arlington Road, Camden Town.

Detective-Sergeant Draper said that he found upon the prisoner a memo. bearing a number of names, including that of Mr. Banbury.

Asked as to the prisoner's history, Sergeant Draper stated that he had just completed a term of three years' penal servitude, and before that he suffered four years' penal servitude and a term of twelve months for burglary.

Contaminated Milk.

THE Medical Officer of Health for the City (Dr. Collingridge), in a recent report to the Corporation, states that a further investigation into the condition of the milk arriving in London from the country has just been completed in continuation of four similar inquiries instituted between 1902 and 1906. Twenty-four samples of milk were taken, on delivery at Liverpool Street Station, and submitted to Dr. Klein, F.R.S., for bacteriological examination. Of these, 54.2 per cent. were fairly clean, 8.3 tuberculous, and 37.5 dirty and unsatisfactory. Those results strongly emphasised the extremely unsatisfactory way in which the milk trade was conducted. Two samples containing the tubercle bacillus, and capable of causing tuberculosis in the human being, came from cows suffering from tuberculosis. Practically no precautions were taken either by farmers or by wholesale dealers in London to ensure that their milk was not a vehicle for the conveyance of tuberculosis. As to the samples reported to be impure and dirty, they were accounted for by the dirty condition of the sheds and premises where the cows were kept and the milk stored. The real method of dealing with the milk question was at the actual source—the farm—and there was no real difficulty in getting this effectually carried out on the spot by the local authority. In any case of default by a local authority the Board of Agriculture should take action and charge all expenses incurred against such authority. Other factors conduced to the unwholesome state of the milk on its arrival in London—such as the system of mixing at the railway stations.—*Times.*

The National Maternity Hospital, Dublin.

THE annual meeting of this hospital was held during the past week. The report stated that in the short space of twelve years this hospital has grown to be the third in size in the United Kingdom. The large outlay on the new wing has completely exhausted all the resources of the hospital, which has to depend entirely on the public for support. This wing, which was opened on December 18th, 1906, gave 40 additional beds for the accommodation of patients, as well as rooms for students and nurses. The new operating theatre now being finished will be as fully and efficiently equipped as any in the United Kingdom. The outlay connected with the erection and equipment of the new wing has amounted to £4,000. The expenditure of this large sum has completely exhausted the resources of the institution, but the necessity of this improvement was so urgent that the governors felt it their duty to carry out the improvements, trusting to the generosity of the public to recognise the merits and claims of the hospital. The report was adopted, and also a resolution calling for support for the hospital.

Royal University of Ireland.

AT a meeting of the Senate, held on February 6th, the following medical appointments were made:—

Fellow: A. E. Dixon, M.D., Professor of Chemistry, Queen's College, Cork. Medicine: James A. Lindsay, M.A., M.D.; Joseph F. O'Carroll, M.D. Surgery: Thomas Sinclair, M.D., M.Ch. Pathology: Edmond J. McWeeney, M.A., M.D.; A. E. Moore, M.B., B.Ch., B.A.O.; W. St. Clair Symmers, M.B. Midwifery: Sir John W. Byers, M.A., M.D., M.A.O.; Alfred J. Smith, M.B., M.Ch., M.A.O. Medical Jurisprudence: Patrick T. O'Sullivan, M.D. Materia Medica: Martin Dempsey, M.D.; Sir William Whitla, M.A., M.D. Ophthalmology: Arthur W. Sandford, M.D., M.Ch.; Louis Werner, M.B.; Phrenology: T. H. Milroy, M.D. Diploma in Public Health: Sir Charles Cameron, C.B., M.D.

It was ordered that a meeting of Convocation be summoned for Tuesday, May 12th, at 4 o'clock p.m., to fill the five vacancies which will then have arisen on the Senate amongst the members elected by Convocation.

Conjoint Examination in Ireland by the Royal College of Physicians and the Royal College of Surgeons.

The following candidates have passed the Final Professional Examination, February, 1908:—

P. Blake, W. H. Bomford, F. P. Byrne, T. Fehily, M. J. Glancy, R. de S. B. Herrick, P. J. Holmes, J. Humphreys, P. MacCarthy, J. V. O'Hagan, W. H. O'Riordan, J. R. Talbot.

The following candidates have passed the Diploma in Public Health, February, 1908:—

Martha Adams, M.B., Robert Muschamp, L.R.C.P. and S.Edin., John James Scanlan, L.R.C.P. and S.Edin.

Royal College of Surgeons in Ireland.—Dental Examination.

THE following candidates, having passed the necessary examination, have been admitted Licentiates in Dental Surgery of the College:—Mr. A. E. Weinstock and Mr. B. Wilson. The following passed the Primary part of the examination:—Mr. M. Keogh and Mr. S. R. Macnamara.

IT is announced that the Oxford University Press will publish immediately the Fitz-Patrick Lectures, delivered before the Royal College of Physicians of London by Dr. Norman Moore, under the title "The History of the Study of Medicine in the British Isles." The first of the lectures treats of medical study in London during the Middle Ages; the second deals with the education of physicians in London in the 17th century; and in the third and fourth lectures the history is told of the study of clinical medicine in the British Isles. The volume contains numerous illustrations.

NOTICES TO CORRESPONDENTS, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTICEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. Half Page, 13 insertions, at 35s.; 26 at 32s.; 52 at 30s. Quarter Page, 13, at 18s.; 26 at 16s.; 52 at 15s. Eighth Page, 13, at 9s.; 26 at 8s.; 52 at 7s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

A Labour Delegate.—We are still puzzling over your effusion. Is it funny? or what? In any case, we cannot publish anything unauthenticated.

L. D. (Bradford).—We have duly forwarded your letter to the Incorporated Institute of Hygiene.

Meetings of the Societies, Lectures, &c.

Wednesday, February 19th.

Royal Microscopical Society (20, Hanover Square, W.).—8 p.m.: Mr. C. L. Curties and Mr. J. E. Barnard: Exhibitions of Slides and Lamp. Mr. E. M. Nelson: Eye-pieces for the Microscope. Rev. E. Tozer: The Life History of a New Protophyte. Mr. F. Chapman: On Dimorphism in the Recent Foraminifer, Alveolina Boscii.

Royal College of Surgeons of England.—5 p.m.: Prof. V. Bonney: A Study of the Connective Tissues in Carcinoma and in certain Pathological Conditions preceding its Onset. (Hunterian Lecture.)

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. J. Pardoe: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. J. Mackenzie: The Nature of the Symptoms in Heart Failure.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Cliniques: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr R. P. Brooks).

Great Northern Central Hospital (Holloway Road, N.).—2.30 p.m.: Surgical In-patients (Mr. Stabb); Medical Out-patients (Dr. Horder); Gynæcological (Dr. Lockyer); Skin (Dr. Whitfield); Teeth (Mr. Baly); Operations (Mr. Stabb).

Thursday, February 20th.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. T. W. Eden: The Examination of Pregnant Women before Labour.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Lecture:—Mr. W. Edmunds: Surgical Aneurysm.

Great Northern Central Hospital (Holloway Road, N.).—2.30 p.m.: Medical In-patients (Dr. Morison).

St. John's Hospital for Diseases of the Skin (Leicester Square, W.C.).—6 p.m.: Lecture:—Dr. M. Dockrell: Syphilis as it Modifies other Eruptions of the Skin: Symptoms, Diagnosis, and Treatment.

Hospital for Sick Children (Great Ormond Street, W.C.).—4 p.m.: Lecture:—Dr. Still: Dyspepsia in Children past the Period of Infancy.

Throat Hospital (Golden Square, W.).—5.30 p.m.: Mr. Rose: Intra-Cranial Complications—Treatment.

Friday, February 21st.

Society of Tropical Medicine and Hygiene (20, Hanover Square, W.).—8.30 p.m.: Fleet-Surgeon P. W. Bassett-Smith: Kala Azar in the Royal Navy (with illustrative cases). Sir Patrick Manson: A Case of Kala Azar ending in Recovery. Dr. J. Cropper: Phenomenal Abundance of Malarial Parasites in the Peripheral Circulation from a Case of Pernicious Malaria in the Jordan Valley.

Society for the Study of Disease in Children (11, Chandos Street, Cavendish Square, W.).—5 p.m.: Dr. G. Carpenter, Dr. E. Cautley, Dr. Whipham, Dr. P. Parkinson, Mr. G. Pernet, Mr. M. Yearsley, Mr. S. Stephenson, and others: Cases. Mr. H. S. Clogg: A Case of Intestinal Obstruction, Resection of a Foot of Gangrenous Intestine, Recovery.

Royal College of Surgeons of England.—5 p.m.: Prof. V. Bonney: A Study of the Connective Tissues in Carcinoma and in certain Pathological Conditions preceding its Onset. (Hunterian Lecture.)

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. A. Lawson: Clinique. (Eye.)

Colyer's Paper: "The Treatment of Children from a Dental Aspect"

Appointments.

Chisolm, R. A., M.B., B.S.Oxon., Assistant Physician to the North-Eastern Hospital for Children, Hackney Road, Bethnal Green.

Creswell, A. H., L.S.A., Certifying Surgeon under the Factory and Workshop Act for the Cinderford District of the county of Gloucester.

Hall, George, M.D.Lond., B.Sc.Durh., M.R.C.P.Lond., Honorary Pathologist to the Royal Victoria Infirmary, Newcastle-on-Tyne.

Hawes, Ivon Henry Skipwith, M.B., B.S.Durh., Medical Officer and Public Vaccinator for the No. 4 District of the Chipping Sodbury (Gloucestershire).

Hughes, Robert, M.B.Lond., Medical Officer to the School Management Committee, Fenton, Staffordshire.

Morgan, David James, M.D., B.C.Cantab., D.P.H.R.C.P.S., Medical Officer of Health of the County Borough of Swansea.

Race, John Percy, L.R.C.P.Lond., M.R.C.S., L.S.A., Assistant Medical Officer at the Joint Counties Asylum, Carmarthen.

Revie, A., M.B., C.M.Glasg., Certifying Surgeon under the Factory and Workshop Act for the works of Messrs. Grant, Ritchie, and Co., Limited, at Kilmarnock, in the county of Ayr.

Webb, Gilbert L., M.B., B.C.Cantab., Resident Medical Officer at the British Lying-in Hospital.

Vacancies.

Nottingham City Asylum.—Second Assistant Medical Officer. Salary, £150 per annum, with board, apartments, etc. Applications to the Medical Superintendent.

Kent County Asylum, Maidstone.—Male Fourth Assistant Medical Officer. Salary, £175 per annum, with furnished quarters, attendance, coals, gas, garden produce, milk, and washing. Applications to the Medical Superintendent.

Catholic University School of Medicine.—The Chair of Medical Jurisprudence and Hygiene. Applications to the Registrar, Medical School, Cecilia Street, Dublin. (See advt.)

Joint Counties Lunatic Asylum, Carmarthen.—Second Assistant Medical Officer. Salary, £160 per annum, with board, lodging, washing, and attendance. Applications to W. Morgan Griffiths, Solicitor, Clerk to the Visitors, Carmarthen.

Nottinghamshire Education Committee.—School Medical Officer. Salary, £300 per annum and travelling expenses. Applications to H. Handford, M.D., County Medical Officer of Health, The Shire Hall, Nottingham.

Metropolitan Hospital, Kingsland Road, N.E.—Casualty Officer. Salary, £150 per annum. Applications to Charles H Byers, Secretary and House Governor.

Royal College of Surgeons of England.—Examiner in Dental Surgery. Application to the Secretary. (See Advt.)

Norfolk County Council.—Medical Officer of Health. Salary, £500 a year. Applications to G. Christopher Davies, Clerk to the Norfolk County Council, The Shirehouse, Norwich.

Barnsley Hall Asylum, Bromsgrove, Worcestershire.—Second Assistant Medical Officer. Salary, £150 per annum, with furnished quarters, board, washing, and attendance. Applications to the Medical Superintendent.

Births.

Hedley.—On Feb. 13th, at 56 Hans Place, London, to Dr. and Mrs. Edward Hedley, a daughter.

Phillips.—On Feb. 16th, at 88 The Avenue, Ealing, the wife of George Phillips, M.D., of a daughter.

Yunge-Bateman.—On Feb. 15th, at 15 Castle-hill-avenue, Folkestone, the wife of Marcus G. Yunge-Bateman, M.R.C.S., of a son.

Marriages.

Heath—Addison.—On Feb. 14th, at St. Paul's Church, Avenue Road, Regent's Park, Philip Maynard Heath, M.S., F.R.C.S. son of the late Christopher Heath, LL.D., F.R.C.S., to Dorothy Mary Rosamund, only daughter of Joseph Addison, of 76, Avenue Road, London.

Deaths.

Gandy.—On Feb. 13th, at Hill Top, Upper Norwood, Surrey, William Gandy, M.R.C.S.Eng., L.S.A., Surgeon-Colonel 2nd V.B. East Surrey Regiment, Divisional Surgeon, Metropolitan Police, aged 67.

McDonald.—On Feb. 14th, Emma McDonald, of 19 Palliser Court, relict of Alexander McDonald, M.D., Fleet Surgeon, R.N., Blane medallist.

Penn.—On Feb. 15th, at 13 Eardley Crescent, London, Agnes, widow of the late William Cecil Penn, M.R.C.S., L.S.A., aged 68.

Bronchial Asthma.

Many physicians consider Angier's Emulsion an extremely valuable adjunct to the treatment of bronchial asthma. As this affection owes its causation and continuation to a chronic inflammatory condition of the bronchioles, the importance of a remedy which has a soothing, inflammation-allaying effect upon the respiratory organs, is easily appreciated. That Angier's Emulsion has this effect is universally conceded. It has a selective influence upon the engorged bronchial and pulmonary mucous membrane, whereby congestion is dispersed, and consequently the symptoms of irritation (cough and asthmatic attacks) are effectually removed. Moreover, these patients are nearly always deficient in constitutional vigour, and Angier's Emulsion helps them by its pronounced effects as a nutritive tonic and reconstructive.

FREE SAMPLES TO THE MEDICAL PROFESSION.

ANGIER'S EMULSION

(Petroleum with Hypophosphites).

THE ANGIER CHEMICAL CO., Ltd., 32 Snow Hill, LONDON, E.C.

By Appointment to H.M. the King.

Cyllin Inhalant

as given off by the Cyllin Inhalator is most beneficial in all diseases of bacterial origin in the mucous lining of the throat, nose, and ears.

In Influenza

its germicidal action on the specific bacillus situated in the superficial layers of the mucous membrane of the respiratory tract, renders valuable assistance.

Cyllin is also put up as a Syrup, and in Capsule form (Palatinoids) for stomachic and intestinal antisepsis.

See pamphlet entitled "Standard Chemical Disinfectan's." Copies, together with working samples, sent gratis and post free on applying to

Jeyes' Sanitary Compounds Company, Ltd.,

64, Cannon Street, London, E.C.

The published statements of prominent surgeons of all countries show that

ARGYROL

(Silver Vitellin)

is the best silver salt, and that no known agent can compare with it in eradicating gonococcal and other infections, speedily and without discomfort to the patient.

Argyrol is used in 10 per cent. solution as injection in gonorrhœa every 3 hours; in 25 per cent. solution as instillation (diseases of eye) every half hour or hour, and in 25 per cent. solution as local application (throat, vagina, etc.) once daily.

Produced by

BARNES & HILLE,

32 Snow Hill, LONDON, E.C.

One unique effect of

OVOFERRIN

(Iron Vitellin)

is its property of improving the patient's general nutrition in a very striking manner.

Literature on Ovoferrin by recognized authorities in medicine in America and Europe, show that it is a hæmatinic and general tonic of very unusual value.

Ovoferrin is furnished by chemists, on prescription, in twelve-ounce bottles. The dosage is one tablespoonful in wine-glass of water or milk three times daily.

Produced by

BARNES & HILLE,

32 Snow Hill, LONDON, E.C.

"A distinct advance on Easton's Syrup."

—The Lancet.

"Bynin" Amara

'BYNIN' AMARA is an analogue of Easton's Syrup, in which the sugar is replaced by an active Malt Extract. This affords a far better vehicle than syrup, as it is actively digestive and nutritious, and there is not the likelihood of the sugar crystallizing out, and carrying down in the crystal the alkaloid principle.

As a digestive tonic, therefore, 'BYNIN' AMARA is not only safer to take than Easton's Syrup, but is of greater value both in aiding and strengthening the powers of assimilation.

It has been found very effective in neuralgia and similar nerve troubles.

COMPOSITION.

Quinine Phosphate	1½ grains.
Iron Phosphate	2 ,,
Nux Vomica Alkaloids equal to Strychnine	$\frac{1}{16}$,,
'Bynin, Liquid Malt	1 ounce.

DOSE FOR ADULTS—One dessert to one table-spoonful, suitably diluted.

A Sample Bottle will be sent free to Medical Men, on request.

NOTES AND COMMENTS.

Lord Lister's Birth Place.

West Ham is a district which does not savour very sweetly in the public nostrils at the present moment, for reasons which are as regrettable as they are notorious. It is, however, most unfair to judge a district by the publicly-exposed faults of a few prominent rapacious scoundrels, and to those acquainted with the inwardness of public life, as represented by certain local bodies, it is no secret that the type of fault committed by the late West Ham Guardians is by no means unique. Moreover, West Ham has had peculiar difficulties to face in the construction of local government machinery, for probably no place has grown from a hamlet to a town with such extraordinary rapidity, nor had to accommodate a larger number of poor at such short notice. But we confess that we ourselves, in good company we have no doubt, did not know the great tradition which West Ham is heir to, a tradition which brings it at one bound to the rank of Stratford-on-Avon and Burnham Thorpe. It has remained for Dr. Pagenstecher to point out to the local Town Council that West Ham is the birth-place of the author of antisepsis, and we fancy that a hundred years hence the name Lister, which now has magic chiefly for foreigners, will be recognised by the people of this country as possessing virtue not less than is associated with those of Shakespeare and Nelson, and the flat, unromantic Essex town where he was born will be the object of pilgrimages no less reverent than those which once found their way to Canterbury and Rome. The house, then known as Upton House, where Lord Lister first saw light, is now St. Peter's Vicarage, and faces into Upton Lane, but eighty years ago it was doubtless as plentifully surrounded by trees and fields as it now is by rows of artisan dwellings and chimney-pots. But, thanks to Dr. Pagenstecher, the momentous event which it witnessed is to be commemorated by a tablet placed in its walls, and now that we do not believe in shrines that tablet should act as a lodestone to draw to it for veneration all those who have receeived the benefits which modern surgery is capable of conferring.

Crates for Cradles.

The Government's Children's Bill which we spoke of last week proposes, among other things, to tackle the question of what its draughtsmen are pleased to call "overlaying." Medical men generally will be as much in sympathy with the object of the provision as they will be out of sympathy with the literary solecism by which the offence is described. The confusion of the verbs "to lie" and "to lay" is, if we mistake not, primarily a Cockney, or South country, fault, though it has permeated to districts far removed from the kingdom of Cockaigne, but it is naturally regarded as a shibboleth that marks off certain sections of society from others. To find that the desire to prevent overlaying has so overlaid the intuitive perceptions of a Minister of State that he describes it as "overlaying," cannot but be a shock to the purist, and if this dreadful word finds its way to the Statute Book the error will be stereotyped for all time. The calamity—that is, the physical, not the literary one—admits of a simple remedy, namely, the provision of cots for children, and the financial problem that a cot presents to the poor mothers has been solved by a good lady in Newcastle, who points out that a banana crate, which can be bought for twopence, is capable of being made into an admirable cradle. The family which has nine months to ruminate on the forthcoming advent of an infant to its midst must be poor indeed if it cannot save that modest sum, and now that overlaying is to be made a criminal offence, the alcoholic mothers will be well advised to lay it by against the birth of their next baby.

A Princely Medical Benefaction.

It is not often that the means of medical men are so large, or their professional earnings so bountiful, that they are able to confer benefactions on their fellow creatures, and the good that they do charitably is generally confined to acts of personal service. The offer made by Dr. Henry Maudsley to the London County Council last week ,namely, the gift of £30,000 to found a hospital for acute mental patients, if not unique, must be very nearly so. And it is as enlightened as generous. Mental disease, if one may use the current phraseology, is still regarded by the public as a rare infliction which immediately qualifies the sufferer for segregation from society for the whole or the best part of his natural life. As a matter of fact, it is probably one of the commonest of the ordinary ailments, but as it masquerades under such euphemism as neurasthenia, nervous break-down, or over-strain, its frequency escapes observation. Correspondingly little attention is paid to it, and equally little provision is made for its treatment and study. Residence in a doctor's house, the doctor probably a busy man with many outside engagements, or a nursing-home, the proprietor of which may be kind, but is probably injudicious, enables the well-to-do to escape the "stigma" of an asylum, but the poor usually either stay at home till they commit suicide or drift into chronic disorder, or are consigned to the county asylum, where frequently but little machinery exists for their special requirements. Hospitals such as Dr. Maudsley suggests are badly needed, but it is a little curious that the County Council should have been chosen by him as the authority to administer the scheme. That body could at a stroke of the pen initiate such institutions to-morrow, with the wealth of the London rates at their back.

The Only Way. At the Manchester Assizes last week a very satisfactory result was arrived at. A civil action was brought by the wife of a Darwen weaver, Mrs. Johnson by name, against one, George Hall, of "Dr. Hall's Hygienic Company, Pendleton," for negligent treatment. Her case was simply this: She went to the defendant and consulted him as to a tumour in her breast, and he advised a certain medicine, telling her that an operation would not effect a cure. It was not alleged that the ointment did harm, but it was alleged that it did no good, and that in consequence of the bad advice given her she neglected to consult a surgeon, and that the tumour, which was small at the time of the consultation, had now become so large that surgical treatment was out of the question, and the patient's life could not be prolonged beyond six months or so. After a full trial, the plaintiff was awarded £600 damages, a verdict which gives us the greatest satisfaction. And for this reason: It shows that the machinery of the law as it stands is already capable of providing a powerful instrument against the quack, who by ignorance or mendacity promises more than he can perform. The quack relies upon untruth; he is not content to advise treatment, but promises cure. The medical man does precisely the opposite. Logically, the quack who promises a cure and does not perform it, cannot escape from the conclusion that he has obtained money by false pretences, and if by civil process it is possible for each disappointed patient to obtain heavy damages, the game would certainly not be worth the candle. The case of Mrs. Johnson is the first we remember which was strictly on this line of argument, and we can only hope it will be duly noted by all the disappointed dupes of quack machinations. If so, the knell of unqualified practice has tolled.

The R.C.S. and Members. In the House of Commons, Sir William Collins has obtained from the Prime Minister a statement as to the result of the negotiations undertaken by the Lord President of the Council with the College of Surgeons with a view to obtaining for members some share in the government of the College. The answers given in effect were that the Government sympathises with the members, but that the Council of the Royal College of Surgeons are not amenable to the arguments of reason and justice presented. We cannot but think that the haughty obstinacy in the Committee of the Council of the College could hardly be better shown than by the fact that independent statesmen express sympathy with the members in their desire to have a hand in the management of their own College; at least, the College which has taken their money and treats them as pariahs. But when we say pariahs, that perhaps is going rather farther than circumstances warrant, for the Olympians of Lincoln's Inn Fields have at last so far accepted the suggestion passed at the annual meeting of Fellows and members that women should be admitted to the examinations of the College, that they are about to circularise the members as to its desirability. It is carefully explained that the right of women to become members and Fellows will not admit them to the government of the College, and we think we see clearly now the object of the amenability of the Council to this suggestion. If the poll be in favour of women they will be admitted to the membership, and the question of sex will be made an additional argument against granting representation to members. The Council will be glad of the women's fees, and they will be in a strong position to refuse representation to members. This is excellent business, especially as they seem to be deferring to the sentiment of present members. We trust the fly will not walk into the parlour.

LEADING ARTICLES.

THE MIDWIVES ACT AND MEDICAL FEES.

The Central Midwives Board have at length recognised the inevitable necessity of making terms with the medical profession if the Act they are called upon to adminster is to become permanently successful. This conclusion has been forced upon them as the result of hard experience, and no longer comes, as it might have done long ago, as the graceful and sympathetic recognition of a bounden right. It is true that a thankless function has been thrust upon them, namely, that of instructing midwives to call in medical men in cases of difficulty and danger, while there is no security that the fees of the medical consultant will be paid. Worst of all, the very members of the medical profession who are thus expected to render help of crucial and inestimable value to unqualified women, have to a great extent been deprived by them of a lucrative branch of professional work. The medical profession, as a rule, is poor and struggling, yet it renders year by year an incalculable amount of gratuitous help to mankind. Of late, however, its patience has been sorely tried. Signs are not wanting that the bounteous spring of philanthropic beneficence which has hitherto issued so freely from the medical profession may be in future somewhat seriously curtailed. It is never safe to demand as a right that which men have acceded, however freely and gratuitously, as a favour. That axiomatic principle of social ethics might well be taken to heart by the Legislature, which appears to think it a perfectly natural and legitimate procedure to wring further gratuitous services from a poor profession that is already saddled with many unremunerated yet responsible burdens by the State. Mr. John Burns recently added a particularly obnoxious straw to the gross burden in the shape of a birth notification that is compulsory (under penalty) but is not paid for. If the President of the Local Government Board should by any chance wish to lessen the stigma attached to that unwise act he may to some limited extent do so by making provision for the adequate payment of medical men who are called upon to give personal services that, from the circumstances of the case, demand possibly the highest technical skill and responsibility that could devolve upon the medical practitioner. A short amending Act for that purpose will probably furnish the speediest and most direct way out of the difficulty, and in our opinion

Sir Campbell-Bannerman's Government could not perform an act of more gracious, if somewhat tardy, concession to a class of men whose rights they have treated in various instances with scant consideration. It will be impossible for the letter to the Privy Council which has been drafted by the President of the Central Midwives Board to pass unnoticed. The contents of that communication have not yet been made public, but enough is known to warrant the statement that it deals clearly and forcibly with the question of the payment of medical men called in by midwives, and the difficulties that exist in the working of the Act owing to the lack of such provision. It is to be hoped that the Privy Council will bring pressure on the Government to remedy a serious defect in the working of a measure that would otherwise be a source of unending bitterness and heart-searching throughout the kingdom. Unless the question of remuneration be settled, local authorities, midwives, and medical men will be in a constant turmoil of potential doubt, wrangling and recrimination. Upon an unstable basis of that kind no legislation could ever become permanently established. The flag of revolt has been formally raised already in some places, and the medical practitioners of a whole district have declined to go to the assistance of a midwife except for a large fee. It is all very well for Dr. Champneys to avow that he is not proud of the attitude of the large majority of his fellow members in the medical profession towards midwives: it was neither humane nor natural. The sentiment is sound, so far as it goes, but the President of the Midwives Board must not lose sight of the other side of the picture. Medical men have to live by the exercise of their profession, and it would be to demand the exercise of superhuman virtue to ask them to smile upon the midwives who are taking from their already exiguous incomes even that paying branch of midwifery which they had. Dr. Champneys, in presiding over the penal functions of the Board, must have had his eyes opened to the irregular medical practice performed by many licensed midwives, who are thus fulfilling to the letter the prophecy made long ago to deaf ears when the Act was in the making, to the effect that a bastard kind of unqualified practitioner would be created. The protection of the lives of our mothers and infants, Dr. Champneys rightly remarks, is, and should be, the first consideration of the medical and midwifery professions. Quite so, but in both cases the labourer is worthy of his hire, but it seems as if the Government appeared to think the midwife should have all the fees, while the medical man should be left to look after himself in the matter. Before the hybrid midwife appeared on the scene the humanity of the medical profession sufficed to meet the needs of the nation, and were rendered gratuitously to an extent that the British public has never realised. Now that the State has seen fit to substitute a lower order of skilled attendant in the shape of the certificated midwife, the duly qualified medical man is quite entitled to stand aloof and demand adequate remuneration when called in to supply the highly technical skill required to meet unusual or complicated cases. We wonder if those who were so clamorous for the higher education of midwives ever thought of the damage that would result to the skill of the medical practitioners through the lessened number of midwifery cases they would attend. After all, the presence of an army of midwives would never make up for the lessened standard of skill or for the straitened fortunes of the general medical practitioners of the United Kingdom.

THE AMALGAMATION OF THE HAMPSTEAD AND NORTH-WEST LONDON HOSPITALS.

THE amalgamation of the Hampstead General with the North-West London Hospital has taken place. The fact in itself marks the measure of a small event, but the issues involved have a great significance to the medical profession, the medical charities, and the public. Hampstead had, by the energy and philanthropy of its inhabitants, secured a small, but efficient, local hospital, for which the general practitioners of the district found no difficulty in providing a medical and surgical staff out of their own ranks. The institution, however, was not allowed to abide in peace, and we trust we are not using too strong an expression when we say it ultimately attained the unhappy position of a kind of Naboth's vineyard. The King Edward's Hospital Fund suggested that the Hampstead Hospital should have a staff of consulting surgeons and physicians. A suggestion of that kind comes with overwhelming force from an autocratic body like that of the Fund in question, which is backed with the bulk of the money available for the hospitals of London. Why they should assume the responsibility of practically wiping out the original medical staff of the Hampstead General is somewhat of a mystery. It certainly seems a very arrogant extension of authority on the part of a Fund, the primary object of which was generally assumed to be that of a judiciary trustee and administrator of public charitable money. Were there any appeal against the decisions of the Fund, were there any explicit or declared policy, were its councils composed of representative persons chosen from various ranks of society, there would be less hesitation in accepting the bureaucratic yoke which this Fund is placing upon the hospital world of London. As things go, the fortunes of many medical charities, as well as of members of their medical staff, are at the mercy of any faddist who happens for the moment to have a ruling voice in the policy of the King Edward's Fund. Not content with the change in staff of the Hampstead Hospital, the Fund further suggested amalgamation with the North-West London Hospital. The effect of this policy cannot be reassuring to the main body of the medical profession. The bitterness of class difference has been thrust upon them by an object lesson imposed by the exercise of forces that are absolutely out of touch with the life and aspirations of the general practitioner. The King Edward's Fund have in effect proclaimed to Hampstead that the medical men of the neighbourhood are not of sufficient skill to attend to hospital patients. The Fund can hardly wonder if their work does not in future flourish in the district of Hampstead, where so wanton and unnecessary a slight has been placed upon local practitioners. Were the medical men of the metropolis to rise in a body and protest against the unwarrantable interference of the King Edward's Fund their influence would speedily be felt. Why should not the King Edward's Fund be managed by a representative body like that of the Hospital Saturday Fund? The day of autocratic control of public funds has passed away, and the only methods that can permanently secure the public confidence in this country is that of representative government. The fact that the excellence of aim and the purity of administration of the King Edward's Fund are above suspicion does not excuse the violation of individual rights and the exercise of irresponsible and indeterminate executive powers. Medical men in the provinces will do well to be warned betimes by what is going on in London, and to see that the management of local medical charities does not drift into the hands of autocratic committees.

CURRENT TOPICS.

Influenza in Downing Street.

The atmosphere of the House of Commons, although carefully purified, appears to furnish an ideal foothold for the influenza germ, if we may judge from the huge number of members of Parliament who have from time to time been laid low by this twentieth century scourge. Perhaps, after all said and done, the House is no more a centre of infection than other large buildings where men do congregate, such as theatres, churches, and public halls. The repeated attacks to which Premiers have of late years been subjected, however, suggest that it would be well to look into the smaller environment of No. 10 Downing Street, their official residence. The well-known fact that the site occupies what was once marshy land, or swamp, in no way prevents the erection of a perfectly healthy dwelling on that particular spot. We presume that the Medical Department of the Local Government Board, if it be their duty to do so, have assured themselves that the subsoil drainage of the area is properly planned and efficient. Further, that the foundations of No. 10 Downing Street, are impermeable to damp and to emanations from the surrounding soil. Last, but not least, that Sir Campbell-Bannerman's official residence is fitted with the best modern systems of drainage and ventilation. We have little hesitation in asserting that although influenza may not be forefended by such an obviously simple and necessary line of defence, yet the risk of its invasion may be considerably lessened by a little timely sanitary precaution. Even at this stage of the influenza epidemic, after many years of loss and suffering, medical science is still completely baffled when it comes to the question of prevention or eradication.

Milk-blended Butter.

Last week a question in the House by Mr. O'Shaughnessy drew attention to the question of milk-blended butter. Under the Butter and Margarine Act of 1907 the Board of Agriculture is empowered to sanction the sale of milk-blended butter under various names. It was admitted by Sir E. Strachey that nineteen names had up to the present been officially sanctioned by the Board, and that amongst them was "Peark's Own." If, as appeared to be suggested by the question, butter is sold containing an undue proportion of water, the interests of the consumer demand some further revision of the Act. Butter is butter, and no article should be allowed to be sold under the name which does not conform to a reasonable standard article. Nor should substitutes be enabled to pass in an indirect way so as to mislead the customer under the guise of fancy names of a non-descriptive character. In our opinion, the nature of any butter substitute should be clearly stated on the attached wrapper or containing package, with the name and address of the vendor, and possibly also of the wholesale agent. There are large agricultural interests concerned in the maintenance of a good wholesome standard of butter, and under wise guidance a great national source of income could be rescued from the hands of foreign competitors.

The Salt Water Cure.

The *Pall Mall Gazette* recently gave a full account of the new sea-water cure. The discoverer, M. Quinton, like Pasteur, Curie, Röntgen, and other pioneers, is described as a scientist. The treatment is based upon the simple discovery that our blood and the blood of all living beings is merely sea-water, more or less distilled. Having been impressed with this fact, M. Quinton began to turn it to account for the benefit of humanity languishing for the want of those marine salts known to have so powerful an influence on health. The labours of seven years have enabled M. Quinton to produce his salt-water serum, called officially "plasma de Quinton." Remarkable results have, as we might have expected, flowed from the use of the plasma. Nearly all diseases seem amenable to it. Children in the last stages of pulmonary tuberculosis have shown improvement, even from the first dose; terrible cases of eczema seem to be conjured away as if by magic; and limbs covered with varicose ulcers that only seem fit to be amputated, come back to their normal flesh-tints after a month or six weeks' treatment; whilst we are further assured inactivity of the bowels is rectified by the treatment; not is there any reaction whatever. All these wonders, and a good many more, are described in the lengthy article from which we quote. The article ends with an appeal for £400 or £500 to equip a dispensary in London; and we need not doubt that before long a Quinton Cure establishment will be opened in this country. It will take its place by the side of such great institutions as "The Sandow" and the "Nauheim," which in their several ways are doing so much for the relief of diseases, the origin of which has been hitherto entirely unknown to scientific medicine, and of which the treatment has been in consequence so completely at fault. It is evident that scientists like M. Quinton will end by entirely destroying the *raison d'être* of the medical profession, which has been so largely and undeservedly superseded in every department once entirely its own.

Proposed Abolition of Guardians.

Clearly the interests of the medical profession are closely involved in the problem of Poor-law reform. That the present system is costly, cumbersome, antiquated, and open to abuses in various directions, may be assumed as a fairly well established basis of argument. Recent revelations as to the inner workings of certain London boards of guardians have greatly strengthened the hand of the reformer. So far as the metropolis is concerned, the proposals which will be laid shortly before the Poor-law Commission are stated to be of a drastic and far-reaching nature. Briefly, all boards of guardians will be abolished and their administration taken over by the borough councils, while all central duties will be performed by the London County Council and the City Corporation. The scheme includes transference to those two bodies of: (i.) The powers and duties of the guardians of the poor and the sick asylum district managers with respect to all local Poor-law services, including the maintenance of workhouses and infirmaries, casual wards, and outdoor relief. (ii.) Services of a municipal character, viz.: (1) Assessment, in the six cases where boards of guardians appoint assessment committees. (2) Registration of births, deaths, and marriages. (3) Vaccination. It is further proposed that the powers and duties of the Metropolitan Asylums Board, as regards infectious diseases, hospitals, ambulances, and other health services, should be transferred to the Council, together with the special schools and remand homes. The transference of the Asylums Board to a popularly representative Council is a step we have always advocated. All pauper asylums would also come under the central Poor-law authority for London. The scheme includes other important proposals, such as the care of the Poor-law children of the metropolis. Should it be accepted, it will mark a new departure in Poor-law administration, the effects of which must sooner or later be felt throughout the length and breadth of the United Kingdom.

Infant Mortality and the Public.

Encouraged by her success in rousing interest on the tuberculosis question in Ireland, Her Excellency the Countess of Aberdeen has now inaugurated a movement to lessen the high infant mortality which prevails in Dublin and other Irish towns. It is true this mortality is not as high as in many industrial centres of England, but, nevertheless, when one remembers how few manufactures there are in Dublin which employ married women, there is room for much improvement. The high mortality in Ireland is due almost entirely to ignorance, for the mothers, even in the poorest quarters, are, on the whole, kind and attentive to their children. Moreover, they have shown themselves willing to learn proper methods of caring for their children, when instruction is offered to them, and much good might be done by tactful health visitors. The Dublin authorities, in their apathy to all matters concerning the health of the city, are extremely unlikely to do anything on a proper scale in the matter, and consequently, unless private initiative steps in, present conditions will continue. At present, a series of public lectures on health subjects, oganised by Lady Aberdeen, is being given by various medical men and women, and special prominence is being given to matters relating to the care and welfare of the infant. While wishing every success to the movement, there is one point in regard to which we think some caution is necessary: the urging of the establishment of milk depôts for children. While it is advisable that good artificial food may be easy to obtain where breast-feeding is impossible, there is a danger that too much insistence on the virtues of pure milk depôts may tend to discourage mothers from nursing their children.

PERSONAL.

H.M. the Queen has been graciously pleased to accept the post of President of the Glasgow Maternity Hospital, whose new buildings will be opened next August.

As Grand Master of the German Knights of St. John, Prince Eitel Fritz, on February 20th, received the Tibetan explorer, Dr. von Lecoq, and pinned on his breast the gold medal for life-saving conferred on him by the British branch of the Order for the bravery he displayed in saving the life of Captain Sherer, a British officer, in the Karakorum Pass.

Dr. John L. Annan has been appointed Demonstrator of Anatomy to the University of Sheffield.

Dr. Archibald Leitch has been appointed investigator at the Caird Cancer Pavilion of the Dundee Royal Infirmary.

Dr. W. Lloyd Edwards has been appointed Medical Officer of Schools to the Barry Education Authority, at a salary of £250 a year.

The Lord Mayor presided yesterday at the annual general meeting of the Royal London Ophthalmic Hospital (Moorfields).

On Thursday, March 5th, a discussion on "The Treatment of Pneumonia" will be opened by Dr. Samuel West at the meeting of the Harveian Society of London, Stafford Rooms, Titchborne Street, W.

Dr. Wylie will read a paper on "Foul Breath—Its Cause and Treatment," at the next meeting of the West London Medico-Chirurgical Society at the West London Hospital, Hammersmith, W.

Dr. Athelstane Iliff Simey, Medical Registrar of the London Hospital, has been appointed Physician to Rugby School as from next August. Dr. Simey is himself an old Rugbeian.

The following gentlemen have been appointed "Clinical Tutors" at the University of Sheffield:—Dr. Miles Phillips, in Obstetrics and Gynæcology; Mr. Graham Simpson, in Surgery; and Dr. A. E. Barnes in Medicine.

We learn with great regret of the death of Professor Frühwald, the well-known Austrian Physician for Children's Diseases. Professor Frühwald's books were well-known in England and America.

Dr. Henry Campbell gave an address on "The Therapeutics of Diet" at the *conversazione* of the Therapeutical and Pharmacological Section of the Royal Society of Medicine held at the Apothecaries' Hall yesterday.

It is with the greatest regret—a feeling, we are sure, which will be shared by all medical men—that we learn that Mr. J. Hall-Edwards has had to have his left hand amputated as the result of persistent X-ray dermatitis. We cordially hope that the right hand will yield to medical treatment.

It is announced that Capt. Robert Markham Carter, Indian Medical Service, 36th Gifford's Horse, was slightly wounded in the left arm on February 20th at Chora.

A CLINICAL LECTURE

ON

THE TREATMENT OF PANNUS FOLLOWING TRACHOMA BY INOCULATING THE EYE WITH GONORRHŒAL PUS.

By **VILMOS GOLDZIEHER,**

Professor of Ophthalmology at the University of Budapest.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

GENTLEMEN,—The treatment of pannus trachomatosus belongs to the most difficult tasks of practical ophthalmology. Pannus is the chief complication of trachoma, a complication that is much more serious than the original disease. The integrity of the cornea is one of the principal requirements of good vision. Therefore, to keep it intact or to repair its lost integrity is the spring of the whole trachoma-therapeutics.

It is true that many clinicians held the view that we need not separately interfere with the pannus, because the pannus vanishes, as consequence, if the trachoma, as cause, is rightly treated. This is the opinion of Prof. Arls, the founder of the Vienna school. He says that the pannus heals upon the treatment directed to the eyelids, and therefore it does not need separate treatment. Fuchs teaches that a fresh pannus disappears of itself through the proper treatment of the conjunctivæ; only an old pannus requires special treatment. According to my opinion, these statements are right only between very narrow limits; mostly just the very incipient stage of pannus requires a special treatment, because its further development can only then be stopped with some certainty. Nominally, according to my opinion, the pannus is not a specific product of trachoma, but sometimes it is provoked by the excessively irritating treating methods; it being then a keratitis superficialis vasculosa, which implicitly proceeds further, unless we discontinue the cauterisation of the conjunctivæ; and it disappears without any greater harm to the patient only in case of directing our attention upon the cornea. In such cases we may easily succeed in attaining an entire cure.

However, the treatment of an extensive pannus is ever a difficult task, because the malady is lengthy, obstinate, and it leads to the harmful infiltration of the corneal tissue. The complications are different; superficial ulcers, changes in the curvature, latent iritis, rise of intraocular pressure—shortly, such complications which require the whole art of a skilled oculist.

Amongst the effective methods I have to mention before all the surgical ones, foremost being the application of the galvano-cautery. This interference consists of cutting through every single blood vessel trespassing over the corneal limbus, with a fine glowing platinum sling; or, of the net of vessels were very dense, we cauterise the cornea arch-like parallel to the limbus. I have practised this method with special success, and had pretty good results therewith. However, this method is not only very delicate, but it requires patience and a skilled hand, too. Further on, in cases of a thick pannus, the interference must be repeated several times.

An older method than the galvano-cauterisation is the so-called *circumcisio corneæ*, which consists of the cutting out of the conjunctiva bulbi, a zone running parallel with the limbus. Therewith we do cut the vessels passing in the pannus, not only through, but also out, though only partially; and thus it can be hoped that their peripheral branches, the network of the pannus, become atrophied. Theoretically, only one objection could be brought up against the former operation—viz., the blood vessels of the pannus are connected most probably also with the sub-conjunctival blood vessels, and on this account the desired atrophy of the vessels does not take place. Otherwise, the uncertainty of the result of this procedure is shown by its unpopularity with oculists.

The insufficiency of internal and surgical medication in the severe cases of the so-called *pannus crassus* (carnosus, sarcomatosus) had induced some oculists at about the end of the last century to try the action of the jequirity decoction. Louis Wecker, a Paris oculist, had, by chance, learned that the decoction of the jequirity applied to the conjunctiva causes a violent, purulent fibrous inflammation, after the cessation of which the hyperæmic cornea clears up. This treatment has been widely employed, then; and sometimes good results were attained. I have employed the drug, at first among Hungarian oculists, through the courtesy of Dr. Wecker, and I could only confirm the favourable data given about the jequirity decoction by other oculists. Still, this method of treatment has been omitted, because, according to some oculists, the patients complained of bad consequences, probably from the reason that jequirity has been applied, not only against pannus crassus, but also against the initial stages of pannus. Nay, a few clinicians regarded the jequirity as a "panacea" which was useful in every form of keratitis vasculosa, and in every duskiness of the cornea. Such unjustified application of the jequirity has caused its falling out of favour with oculists on account of the many failures and disastrous consequences arising from its use.

In the latter years—owing to the investigations of Roemer, who succeeded in extracting the acting agent of the jequirity, namely, the abrin—the jequirity treatment came again into vogue. The abrin has the advantageous property of safety, being produced in four strengths, in opposition with the jequirity decoction, the action of which upon the conjunctiva has been pretty uncertain.

However, the application of abrin, too, proved to be unreliable in some cases. It is true that many cases of pannus have healed under its use; still, it seemed that the eye specialists were disappointed with it on account of the harm which arose from its application.

Now I turn to a long-forgotten, quite obsolete method, which can boast at least so much merit that the scientific explanation of the jequirital treatment rests on the successes attained with it. A good many decades ago, in the time when the so-called Egyptian eye inflammation caused a general terror in the time of the Napoleonic war, the doctors had made the experience that if a pannous bulb became blennorrhœic, as the consequence of a direct infection, the vessel-rich cornea not only bore the evil of the intensive purulency, but it even cleared up, too, after its cessation. The transparency of the cornea returned, and it became quite cleared up entirely; the visual power recurred. I do not doubt that—before this fact would have been utilised to therapeutical purposes—the doctors would have ample opportunity of making such observations, because the contagiousness of the Egyptian eye disease had not yet been known then—nay, a considerable number of doctors were inclined to ascribe it to external causes, like dust, heat, and tightly-tied necktie, etc. In this time infectious and non-infectious eye diseases were kept in the same ward, so that infection very easily occurred, thus the opportunity having been rendered to a pannous eye to catch a blennorrhœa and to regain the visual power after the cessation of this. Very probably, on ground of these (by chance) lucky cases, has Frederick Jaeger, the Surgeon-General of the Austro-Hungarian Army, a renowned oculist, regarded the inoculation of blennorrhœa in cases of obstinate pannus as ultimum refugium. As I could elicit from the then literature, Jaeger applied the method often and with marked success. His original communications on this subject appeared in 1870, but these are not obtainable now, to my great sorrow. However, I was successful in finding an epitome of a lecture which was held by Jaeger on this new treatment.

Here I found the following quotation:—"If a case of trachoma terminates unfavourably, with a pannus remaining behind, and when everything that is available has already been tried, nominally ***aqua oxymiriatica***, opiates, regulation of the diet, etc., and the disease is confined to the conjunctivæ, and the internal parts of the eye are devoid of any irritation, then it is advisable to inoculate the eye with the secretion of the lippitudo (blennorrhœa) neonatorum After the cessation of blennorrhœic process, the conjunctiva regains its normal form and function."

It has to be remarked that what Jaeger says, in the last sentence quoted, of the conjunctiva, *i.e.*, that it regains its form and functions, refers to the cornea, because he reckons that the most anterior part of the cornea, in relation to where the pannus exists, is the conjunctiva, which assumption is quite correct and justified from an embryological point of view.

A pupil of Jaeger, T. F. Piringer, chief oculist in Graz (Tyrol), wrote very plentifully on the subject. He is the author of the monograph, "Die Heilung des Pannus dirrch Einimpfung der Blenorrhoe" (the healing of the pannus through inoculation of blennorrhœa). In this book he describes every phase of a blennorrhœic infection, the whereabouts of the infecting agent, its nature and the manner to destroy it. His sayings are based on experiments carried out on human eyes. The ***résume*** of this work is that the inoculation of blennorrhœa for the cure of pannus is as effective a method, as it is devoid of any essential risk on the part of the patient.

From ophthalmological literature I gather that the method has been successfully practised in different countries. Chiefly, the Belgian oculists have declared it "worthy of every praise." As regards Austria, the native country of the method, here we find brilliant names among the friends and followers of the method—Arlt, Stellwag. Arlt says the following in his bulky manual on eye disease:—"Relying on Jaeger's, and particularly on Piringer's statement, I applied the inoculation method in hopeless cases of pannus. In the three cases in which I have done so I had nothing to repent." Similarly writes Stellwag, too, in his manual, although somewhat more reservedly. He says that the inoculation of blennorrhœa is indicated only in the most severe, obstinate, eventually hopeless, cases of pannus crassus.

Since then (the middle of the last century) this method has been quite forgotten. What was the cause of this fact I could not discover. I can only guess that the age of the therapeutic Nihilism, which started out from the Vienna school, has not been favourable for such a method, which, owing to the inoculation of a terrible disease, seemed to be connected with a great danger. However, it is possible that the inoculations had serious consequences on account of negligence in the selection of the cases or in the indications. In the present age of developed bacteriology we would ridicule such an objection as brought up against the method by Saemisch, who said, *ex cathedrâ*, that blennorrhœic inoculations must be avoided for the reason that the inoculated pus may result even in diphtheritis. (Graefe-Saemisch. "Handbuch der Augenheilkunde." I. edition, 4 vol., p. 230.) It is a fact that in the time when the jequirity method became known, the inoculation of blennorrhœa was not practised at all.

The circumstance that the eye section of the St. Rochus Hospital (Budapest) must of necessity admit very severe and neglected cases, which are refused in other hospitals, puts me in front of a very difficult task. Such are the cases of pannus crassus. I encountered several of these desperate cases, where every imaginable treatment was of no use. Then, after having thoroughly studied the literature of the trachoma, I felt myself justified in taking refuge in the trying of the inoculation method; the more so because my patients—in a practical sense of the word—were already blind.

I have the honour to exhibit this patient as a classic example. His case-history is particularly interesting, because it excellently illustrates all the asserted things, and it illustrates also the hard task before which we are standing. The patient, æt. 25, an agricultural labourer, had, as he alleges in 1905, when he became a soldier, entirely good and healthy eyes. Otherwise he is strong and healthy. As a soldier he had infected his eyes, and was for three months attended as an outdoor patient. On July 19th, 1905, he was sent to the Nyitra military hospital, where he has spent 11 months. Here he was treated with every known method, and on June 20th, 1906, he was admitted to our hospital, after being dismissed from the army. His status was as follows:—Photophobia of the highest degree; copious slimy, purulent conjunctival secretion; the conjunctiva tarsi is strongly thickened, with great papillar hypertrophy; among the papillæ there are numerous small nodules, the transitional fold infiltrated, with numerous transparent granules, standing in a straight line. Conjunctival and ciliary injectedness of the highest degree. The cornea was on its whole surface covered with a deep, pink blood vessel network, which was so dense that only the thicker vessel stems could be seen on the limbus. The vision had been reduced to noticing light only. This condition had been uniform in both eyes.

At first I employed the jequiritol treatment, without the slightest result. Later on the condition of the cornæ (especially that of the left one) became so bad that I resolved upon trying the inoculation method. On September 28th I inoculated the left eye with a secretion taken from a blennorrhœic eye. The blennorrhœa broke out on the third day. The patient left the hospital after a month, with an entirely healed blennorrhœa, in order to await at home the clearing up of the cornea. When we saw him again on September 12th, 1907, I noticed a very pleasant change; the cornea was nicely cleared up, although there are fine little spots on its surface; the bulb was devoid of any inflammation; and, what was most surprising, the *tractus conjunctivitis* was sound; there was no trace of the previous trachoma. The status of the right eye has been unchanged; pannus crassus and the succulent trachoma could be seen, the vision reduced to noticing only light. After bacteriological examination of the secretion of the right eye, which revealed no gonoccocci, I inoculated the eye with a gonorrhoeal secretion. The latent stage lasted three days, whereupon a vehement gonorrhoea broke out. The treatment consisted of the cleankeeping of the eye. At present, also, this cornea has cleared up, the conjunctival infiltration has greatly lessened, there is no secretion at all.

From this case and two others already previously treated on similar lines, I can draw the conclusion that the long-discontinued Jaeger inoculation of blennorrhœa can be applied as an ultimum refugium. It is by no means more dangerous than a jequirity-caused ophthalmia. The conclusive indication for its application is the presence of a pannus crassus. It is worthy of special mention that, after the disappearance of the inoculated blennorrhœa, not only has the cornea cleared up, but—in opposition to the results arrived at with jequiritol—the conjunctival tract has also regained its soundness. I intend further to investigate this new field of therapeutics, and from the results of my experiments I will inform you, gentlemen, in due time.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by George F. Still, M.A., M.D.Cantab., F.R.C.P., Physician for Diseases of Children at King's College Hospital, and Professor of Diseases of Children at King's College, London. Subject: "Indigestion in Children."*

LETTSOMIAN LECTURES, 1908.

TUBERCULOSIS OF THE KIDNEY.(a)

By CHARTERS J. SYMONDS, M.S., LOND., F.R.C.S.,

Surgeon to Guy's Hospital.

LECTURE II.

THE Lecturer began by referring to the large, painless, movable, tuberculous kidney as being so well known as to need but a passing reference. In the cases referred to the patients had all given a history of pain of one to three years' duration. In a case operated upon in 1902 there had been frequent micturition in the early stages, then frequent attacks of pain, and as the tumour enlarged, cessation of these symptoms. This patient recovered, and was alive and in excellent health in 1908. The general health of these patients was said to be good, and they were able to work. From a clinical point of view, they resembled pyo- or hydronephrosis in the length of the history, the character of the pain, and the nature of the tumour.

The leading initial symptoms of tuberculosis of the kidney were next passed in review; firstly, renal colic; in many cases it exactly resembled that produced by a calculus, as in Case II., a man of 46, who without any previous symptoms had three attacks of renal colic. Next albuminuria, as an early sign, was commented upon, one of the chief points being the proportion of albumin to the pus, it generally being more abundant than can be explained by the pus. It was pointed out that albuminuria might occur without any other symptoms, and in both that form where the ureter is shut off, as in Case IV., as well as when it is patent. Special atttention was called to the fact that, as miliary tuberculosis is painless, and as extensive destruction may take place without symptoms, an examination for bacilli in unexplained cases of albuminuria was important.

Of hæmaturia as an initial symptom, one case was related; and, though complete demonstration of renal infection was not possible, the man got perfectly well under treatment by tuberculin. Vesical and urethral irritation were shown to be present in a large number of cases without infection of the bladder, and even where vesical tuberculosis existed the irritation was, in some instances, not greater than when the bladder was healthy. The tolerance of the bladder to tuberculous pus was illustrated by several cases. In some the infective material must have entered the bladder for two years or more. This point was thought to be important in view of the danger of such an infection being unduly urged as an argument for immediate operation.

The routine examination of the urine for tubercle bacilli, when small quantities of albumin and pus are found without renal or vesical symptoms, but associated with ill-health and anæmia, will, the Lecturer thought, discover many cases of early tuberculosis of the kidney. The tubercle having been found, the next point was to ascertain the incidence of the disease by means of the cystoscope, segregation, or other methods. He thought, however, that the ureteric orifice would not exhibit characteristic changes until the ureter itself was infected. In the absence of localising evidence, reliance must be placed on hygienic methods and the injections of tuberculin, and by these means he thought there was no reason why early tuberculosis of the kidney should not recover; and he thought that a good many of the cases of albuminuria that did recover had been of tuberculous origin.

How long are we justified in waiting after tuberculosis has been localised in one kidney before operating? That there is no necessity for immediate nephrectomy was shown by the cases recorded in the first lecture. The two principal complications—infection of the bladder and dissemination—are certainly long delayed. He therefore thought that when the bacilli are few, the albumin and pus variable, and where vesical irritation is bearable, the bladder healthy, and the ureteric orifice normal, postponement is justifiable. As to how far complete recovery can be brought about had yet to be ascertained, but he thought that when the ureteric orifice showed positive evidence of disease operation should not be delayed.

He thought that nephrectomy should be performed when the local symptoms indicated progressive destruction of the kidney, as shown by pain, vesical irritation, a lumbar tumour, or the presence of a considerable amount of pus in the urine. These symptoms indicated probably that no recovery could take place in the sense that some renal tissue would be left, and therefore it was better to cut short an illness by removing the kidney. In the absence of the symptoms referred to, he thought the best evidence as to the necessity of nephrectomy was in the appearance of the ureteric orifice.

It was thought that the cases demonstrated that tuberculosis of the bladder was not a contraindication to nephrectomy, especially if the infection was confined to the neighbourhood of the orifice of the infected ureter; and, looking to the well-known recoverability of vesical tubercle, he thought that nephrectomy was justified, even with multiple foci. The question whether slight infection of the other kidney, as indicated by a few bacilli from this side, should contra-indicate nephrectomy when the other was obviously tuberculous was considered, and he thought the question turned upon the distress caused by the obviously affected organ and upon the curability of renal tuberculosis. He expressed the opinion that under such circumstances, where a kidney was causing distress and affecting the health, it should be removed as tending to improve the general health and promote recovery of the remaining kidney. Such a proceeding, he explained, compared with the removal of a suppurating knee-joint with existing phthisis.

(a) Abstract of Lecture II delivered before the Medical Society of London, February 17th, 1908.

The question of whether the ureter should be removed at the same time as the kidney, or subsequently, was next discussed. Cases were quoted to show that a tuberculous ureter might completely recover, even when associated with tuberculosis of the bladder, and that on this ground no strong reason could be given for immediate or subsequent ureterectomy. In one case, however, the ureter had to be removed for a persistent loin sinus and vesical irritation nearly a year after the nephrectomy. It was followed by complete relief. The operation was done in 1897, and the patient was in perfect health at the present time. He quoted another case to show that recovery was more rapid if the ureter were removed at the same time as the kidney. On the whole, he was strongly in favour of this proceeding, provided the patient was able to bear the additional strain; but, looking to the fact that recovery took place when the ureter was left, it was not justifiable to run any risk.

With regard to the method of removal of the ureter, he preferred to separate the muscles, as in the operation for appendectomy, and draw the ureter down. Done at the same time as the kidney, the operation was greatly expedited by the direction given by pulling upon the loin end. He pointed out that the ureter always went up with the peritoneum, and must therefore be sought for on the anterior surface of the wound.

The advantage of preliminary nephrotomy was considered, and was illustrated by Case V., where the general infection was completely relieved, and a successful nephrectomy carried out later. The value of a preliminary incision into the kidney was that it gave an indication of the amount of renal tissue left, that the urine could be collected from the bladder, and the secreting capacity of the other kidney ascertained.

In conclusion, the routine examination of the urine was urged in cases of renal pain and albuminuria; also in all cases of unexplained vesical or urethral irritation and hæmaturia; that nephrectomy should be performed as soon as there was evidence of destruction of the kidney or injection of the ureter; that nephrectomy was not negatived by vesical tubercle nor by slight miliary tubercle of the opposite kidney.

ORIGINAL PAPERS.

GRAFTING OF FIBULA TO TIBIA.

By R. ATKINSON STONEY, F.R.C.S.I.,

Visiting Surgeon to the Royal City of Dublin Hospital.

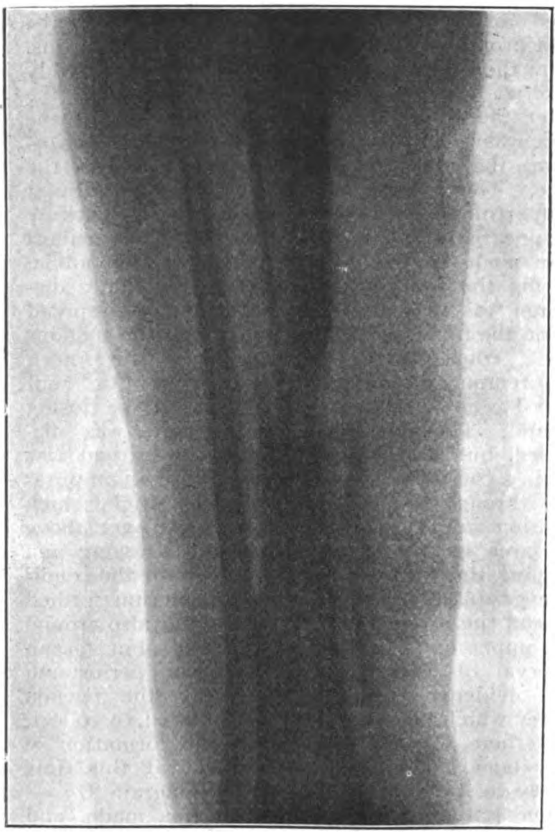
The patient, a boy, æt. 7, was admitted to the Royal City of Dublin Hospital on the afternoon of November 26th, 1904. His temperature and pulse on admission were over 103° F., and 100 respectively. His mother gave a history that he had been ill with pain and swelling of his left leg for some ten days, and also said that he had had an attack of measles about two months previously.

On examination, it was found that the left leg was enormously swollen from the knee to the ankle, the skin was blue and shiny, and fluctuation was well marked. Chloroform was administered and a free incision was made over the most prominent part of the swelling, about 1½ ins. below the knee, and about a pint of pus and shreddy material was evacuated. On introducing the finger the whole length of the diaphysis of the tibia was felt to be bare and denuded of periosteum, the finger passing completely round the bone. The muscles of the anterior tibio-fibular compartment seemed to have almost entirely disappeared. A couple of counter openings were made for drainage just above the ankle. During the following three weeks the daily discharge was very profuse, and suppuration spread up on the inner side of the limb along the tendons for a considerable distance above the knee; the temperature fluctuated between 100° and 104° F., and the patient appeared to be losing ground. The question of amputation was discussed, but it was thought that the patient was not in a condition to stand the shock of an amputation through the upper third of the thigh, which position would have been necessary to get above the area of infection. By careful dressing and keeping the limb in a continuous bath the condition gradually improved; an involucrum formed around the lower half of the tibia and also around the upper end for a short distance; but for an interval of a couple of inches the periosteum had evidently been destroyed by the tension under which the pus had been allowed to collect, and there was no attempt at the formation of new bone. The condition present at this time (early in January) is shown in Skiagram I.

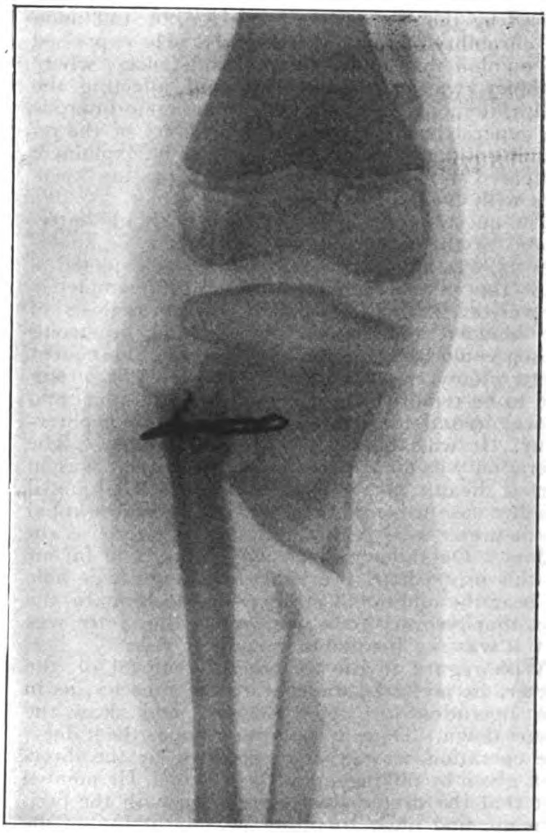
On January 21st an incision was made, and the upper half of the necrosed tibia was removed in one piece. There was no difficulty in doing this as it lay quite loose, without any involucrum surrounding it. The lower half was too firmly fixed to be taken away with safety. Some months later, on the 8th of April, the lower half of the necrosed tibia was removed in several pieces, after making an incision through the involucrum surrounding it. On the 26th of June the sinuses were scraped and several small sequestra were removed. On the 5th of July, after a stay of nearly eight months in hospital, the patient was discharged with the majority of the sinuses healed; but for some time longer he had to attend the dressing dispensary daily.

In the beginning of April, 1906, the patient was re-admitted to hospital with the condition shown in Skiagram II. All the sinuses were soundly healed, the leg was two inches shorter than the opposite one, and there was lateral movement to nearly a right angle at a point a couple of inches below the knee, so that the leg was useless as a means of support or locomotion. On looking at the skiagram it is seen that this mobility was due to a gap in the tibia, about the junction of the upper and middle thirds of the bone; in this interval no new bone had been formed, though it was now eighteen months since the first operation. It can also be seen that owing to the continued growth of the fibula the upper end of this bone was dislocated from the external tuberosity of the tibia and projected up to the level of the knee-joint, forming a marked prominence under the skin.

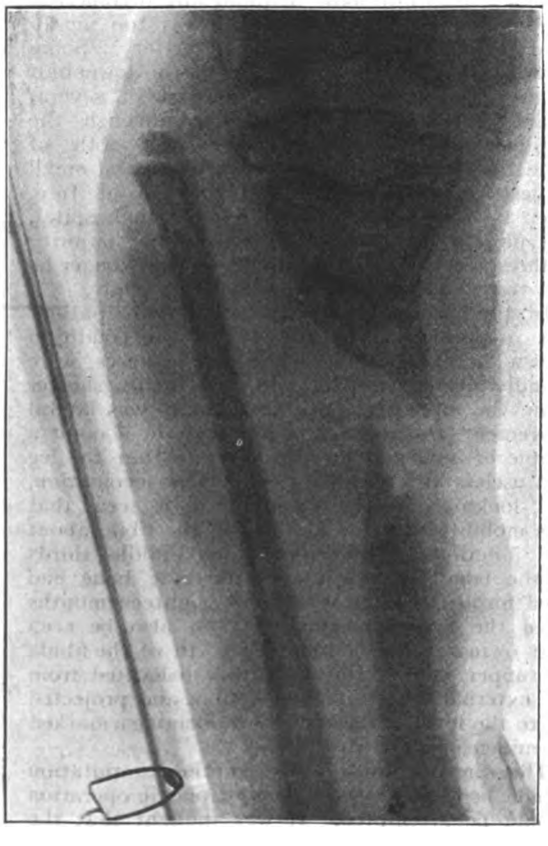
The question arose as to whether amputation should be done, or some form of plastic operation should be attempted. It was thought that the latter would not have much likelihood of success owing to the poor blood supply of the parts, as



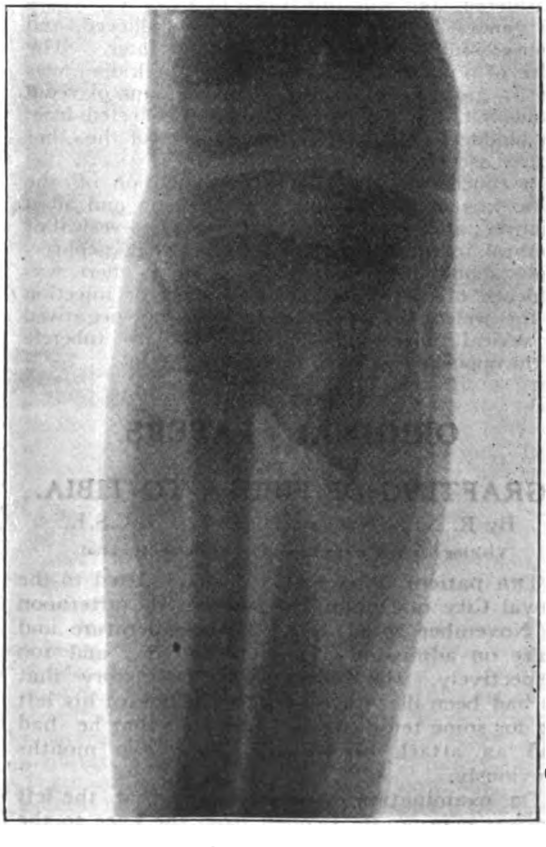
No. I.—Taken Jan., 1905.



No. III.—Taken Oct., 1906.



No. II.—Taken April, 1906.



No. IV.—Taken Oct , 1907.

the upper half of the leg appeared to consist of little more than cicatricial tissue. It was, however, decided to make the attempt.

Several methods suggested themselves :—(1) Removal of a sufficient length of the fibula to allow the two ends of the tibia after freshening to be brought into contact and wired. This would have entailed further shortening of the leg, already considerably too short. (2) The placing of a portion of the fibula or a piece of bone from a recently killed animal between the two ends of the tibia. (3) The transplanting of a piece of the periosteum of the fibula or a slice off the fibula in the gap in the tibia. The great objection to both these methods was the probability that growth and union would not occur owing to the lack of nourishment, as the transplantation would take place in a mass of fibrous tissue, (4) The fourth method, which was that adopted. was to cut across the neck of the fibula just above the level of the lower end of the proximal portion of the tibia, and fix the upper end of the lower fragment of the fibula to the upper piece of the tibia. By this means the graft would retain its own blood supply, and there would, therefore, be less fear of necrosis or failure of union. The idea of this operation was suggested by a case recorded in the *Lancet* of January 13th, 1906, by Prof. E. E. Goldman, of Freiburg, where the upper end of the tibia had to be removed for sarcoma. The operation is a modification of one described by Hahn as long ago as 1885.

The operation was performed on the 7th of April, 1906. Some difficulty was found in bringing the fibula across to the tibia, owing to the fact that the whole of the upper part of the leg was merely a mass of fibrous tissue, showing no trace of muscle. A small cavity was gouged out of the upper fragment of the tibia and the upper end of the distal portion of the fibula was placed in this and fixed in position by a silver wire suture. (see Skiagram III.) Unfortunately some encapsuled mass of sepsis was apparently opened into, for though the surface of the wound healed, an abscess formed around the wire, which had finally to be removed on October 6th. This occurrence of sepsis delayed the union of the bone, but after about ten months spent with the limb in plaster, firm union took place, so providing the boy with a stable column of support for his limb. There is still considerable shortening, due to loss of growth during the eighteen months while the ends of the tibia were not in contact before the plastic operation. Since the operation, however, the limb has been growing at the same rate as its fellow, and the shortening is largely masked by a tilting down of the pelvis and by a talipes equinus which has resulted from the complete destruction of the muscles in the anterior tibiofibular compartment. The patient is now able to walk well, and even to run about without the support of a stick, though there is a considerable limp.

A somewhat similar case is reported in the "Annals of Surgery" for last October, by J. S. Stone But in it there was a much greater failure of formation of new bone in place of the necrosed tibia, so that there was a gap of about eight inches between the two ends. The operation consisted of two stages; the first corresponded almost exactly to that described above, and the second, which was performed some time afterwards, consisted in splitting the lower end of the fibula longitudinally and grafting the inner fragment to the lower part of the tibia.

The condition of the patient last October is shown in Skiagram IV. The plaster had been removed, and the patient was going about. On looking at this skiagram it will be seen that the fibula is fixed to the side of the tibia rather than to its distal extremity; this is partly due to the difficulty that was experienced in drawing the fibula inwards owing to the firm mass of fibrous; cicatricial tissue developed here, and partly to a slipping upwards of the fibula, which occurred as a result of the suppuration which prevented rapid union between the bones. Another point that may be noticed is the great hypertrophy of the fibula which has taken place as the result of having to take on the support of the whole limb. This hypertrophy is very well seen also in the illustrations which accompany both Goldman's and Stone's papers.

ABSTRACT OF A PAPER ON

A RECORD OF A YEAR'S WORK IN THE ROYAL SAMARITAN HOSPITAL FOR WOMEN, GLASGOW.

By J. NIGEL STARK, M.D., F.F.P.S.G.,
Surgeon, Royal Samaritan Hospital for Women; formerly Presiden. Glasgow Obstetrical and Gynæcological Society, &c.

DURING the year 1907 Dr. Stark performed major operations which involved opening into the peritoneal cavity by either the abdominal or the vaginal route on 103 patients. More than 103 operations were actually performed, as on several patients as many as five or six were done. Out of the number three patients died, giving a mortality rate of 2.9 per cent. All three deaths were unavoidable, as can be seen by a study of their causes. It should, therefore, encourage both medical practitioners and patients to know that modern methods of asepsis and the improved technique have in large measure robbed surgical treatment in gynæcology of so much of its former danger, so that sufferers from ovarian or uterine tumours, from chronic inflammatory diseases, from intractable displacements, need not too long hesitate to undergo operation, so far, at any rate, as concerns the prospects of immediate recovery. A large majority of the patients suffered from disease in more than one organ or from injury to several parts. For example, many cases like the following were seen :—Rupture of the perineum, relaxed vaginal walls, lacerated and eroded cervix, endometritis, retroversion and prolapse of the uterus, chronic salpingo-oöphoritis, extensive intestinal adhesions, and even, perhaps, chronic appendicitis. The patients suffering from such complicated and widespread disease were treated at one or two stages. Usually everything was done at one time, and although the series of operations occupied a considerable length of time, yet, with experience and practice, one learns to perform them more rapidly than would at first appear possible. After anæsthetisation, the patient is placed in the lithotomy position, the vagina thoroughly cleansed and disinfected, the cervix dilated—usually to No. 10 Hegar—and the uterus curetted. If the cervix is the seat of chronic hyperplasia and of old-standing lacerations, it is amputated; in less severe cases trachelorrhaphy is performed. Colporrhaphy, anterior or posterior, or both together, follows, and then one of the various methods of perineorrhaphy. The vaginal operations being finished, the patient is placed in the dorsal position; but, after the abdomen is opened, the Trendelenburg attitude is assumed. Adhesions having been separated, the ovaries, tubes, and appendix are dealt with, and ventrofixation or ventrosuspension completes the task, the abdominal wound being sewn up in three layers. It is evident, therefore, that in many patients as many as five or six operations were performed, each of which was absolutely necessary in order to obtain a good result. Bearing this in mind, we may tabulate the operations in the following fashion :—

Operations.			Total.	Mortality.
Hysterectomy (abdominal)	Fibromyoma of body of uterus ...	15	19	0
	Fibromyoma of cervix of uterus...	1		
	Fibrocystic tumour of uterus ...	1		
	Double pyosalpinx and pyometra	1		
	Carcinoma of uterus	1		
Myomectomy	Fibromyoma of uterus—sub-peritoneal	1	2	0
	Fibroma of uterus with pregnancy	1		
Hysterectomy (vaginal)	Carcinoma of the body and cervix of the uterus		2	0
Hysterectomy and Cæsarean section	Carcinoma cervicis and full-term pregnancy		1	1
Ovariotomy	Multilocular ovarian cystoma—			
	Bilateral	2	5	0
	Unilateral	3		
	Gangrenous cyst with twisted pedicle...		1	0
	Papilloma of the ovary		1	1
Salpingo-oöphorectomy	Chronic salpingo-oöphoritis—			
	Bilateral	11	17	0
	Unilateral	6		
	Abscess of ovary		1	0
Salpingotomy	Pyosalpinx—			
	Bilateral	1	3	1
	Unilateral	2		
	Hydrosalpinx, unilateral		1	0
Removal of sessile cysts of broad ligament			3	0
Ventrofixation and Ventrosuspension	Retroversion		11	0
	Prolapse		20	0
Laparotomy for Extra-uterine pregnancy	Full term		1	0
	Tubal abortions and ruptures ...		5	0
Laparotomy and drainage	Purulent peritonitis		2	0
	Pelvic abscess		1	0
Laparotomy	Tubercular peritonitis		3	0
Radical cure for ventral hernia...			2	0
Laparotomy; uncompleted operations	Cancer of ovary, intestines, &c. ...		2	0
			103	3

Hysterectomy for Fibromyoma.—No deaths occurred. One interesting case was that of fibroid of the cervix, already reported in the *Journal of Obstetrics and Gynæcology of the British Empire.* It attained the weight, great for a cervical fibroid, of 17½ lbs. In every case the recoveries were rapid and uneventful, even when there had been serious difficulties in the operations and long-continued previous bad health, and in no other patients did one feel more fully repaid for what one did for them. As the good results continue and endure, it seems unfortunate that even yet there is such a tendency to conservatism on the part of many practitioners, and that so many women struggle on for years, burdened by a fibroid tumour of the uterus, when relief could be given and life rendered more worth living by what is now a comparatively safe operation.

It is impossible to detail cases at length in an abstract of a paper, much as one would like to do so. A most interesting one was that of carcinoma of the cervix associated with pregnancy. The patient was 36 years of age, and in 10½ years had given birth to 9 children. The cervix was converted into an indurated, ulcerated, bleeding mass. Cæsarean section was performed, then panhysterectomy. Fair progress was made until the fifth day, when the temperature was 100 deg. F., and nourishment was being well taken. In the evening sudden faintness and collapse came on, and death ensued in 20 minutes. At the autopsy no other abnormal conditions were found than enlargement and acute fatty degeneration of the liver and fatty heart. A very large number of cases of chronic salpingo-oöphoritis, of prolapse of the uterus, and of retroflexion, associated with disease of the appendages, were encountered, as is to be expected in a large manufacturing city where so many of its inhabitants are the subjects of gonorrhœa, and where so much carelessness and neglect occur during and after childbirth. As a rule, great benefit results to these cases from the stay in hospital, and many leave feeling in better health than they have been for years.

Of the extra-uterine pregnancies, one was at full term—or, rather, had gone beyond full term. The patient was 26 years of age, a multipara. There had been symptoms during the early months suggestive of extra-uterine pregnancy, but these passed away, and later on fœtal movements were felt. A doctor was engaged to attend at the expected confinement. When full term arrived active movements ceased, and three weeks later Dr. Stark was called in consultation. The uterus could be felt empty, and the patient was removed to hospital. At the operation the child was found lying transversely in a sac composed of the layers of the broad ligament, and without any difficulty child and sac were removed along with the placenta which was lying on the breech. The operation was of surprising ease. The child, placenta, and cord were well developed, and, had it been possible to diagnose the condition at an earlier date, a living child could have been removed which would have had a reasonable chance of continuance of life; but the mother had no suspicion that everything was not normal in every respect. The recovery was perfect.

OPERATING THEATRES.

CHILDREN'S HOSPITAL, PADDINGTON GREEN.

Operation for Imperforate Rectum.—Mr. Arthur Edmunds operated on a male child, æt. 3 days, who had been admitted for persistent vomiting; there was also a history that the child had passed no meconium and no urine. On examination, the little patient was found to be well nourished, though rather a small child. On passing the finger into the rectum an obstruction was felt about three-quarters of an inch from the anus. The abdomen was distended, but not very markedly so, and there was a slight musical bruit over the heart, possibly due to a patent foramen ovale. Mr. Edmunds remarked that this was a comparatively rare condition, although it was very well-known, occurring about once in every 7,000 births. The exact etiology of the condition is by no means as clear as it would at first sight appear to be. Some cases are undoubtedly due to a persistence of the cloacal membrane, a structure which normally consists of two layers of epithelium with a small amount of mesoblastic connective tissue in its anterior portion. It is quite easy to see how an excess of this connective tissue in the cloacal membrane might lead to a persistence of the structure. The obstruction produced by this error of development takes, however, the form of a diaphragm just within the anus which bulges at the orifice and requires merely an incision to give exit to the bowel contents. The case in question probably fell under an entirely different heading. Many cases have been described in which a portion of the alimentary is entirely undeveloped, or is represented by a cord-like structure attached to the free border of the mesentery. In these cases the obstruction may be at any part of the alimentary canal, or even in several situations, normal intestine alternating with patches of completely undeveloped bowel. It is probable that the portion of intestine most commonly affected in this way is the lower portion of the rectum, and in cases of imperforate rectum it is quite common to find the blind end of the gut connected to the anal canal by a fibrous cord, which represents a considerable length of undeveloped intestine. It follows from this that, although the upper blind end may be in actual contact with the termination of the anal tube, the gap between them would be considerable if the intestine were straightened out. In consequence, the peritoneum covers the upper end of the bowel almost completely, so that if a trochar be thrust through the anus into the meconium containing rectum, the instrument will pass across a diverticulum of the peritoneum. At the moment of puncture the two are in apposition, the distended end of the bowel usually filling the pelvis completely. As soon, however, as the obstruction is relieved, the rectum recedes, and its contents then tend to become discharged into the peritoneal cavity. A condition is described and figured in nearly every text-book of surgery in which a diaphragm exists across the bowel about an inch from the anus. This could be treated quite efficiently in the same way as persistent cloacal membrane—namely, by simple incision; but, unfortunately, the condition, if it occurs at all, is extremely rare, and there is no doubt that what he had just described was very commonly mistaken for a simple diaphragm, and attempts made to relieve the patient by thrusting in a trochar. The fact that statistics show that most of these cases die from septic peritonitis is strong evidence that this mistake has been made. In the present case the child was anæsthetised and held in an appropriate position, with the buttocks pointing upwards, by an assistant. As a precaution against shock, an ounce of saline was injected into the right axilla, and a 1-100th of a grain of strychnine administered subcutaneously, both of which measures are much more valuable, Mr. Edmunds said, for preventing shock than for relieving it when it has once become established. An incision was then made strictly in the middle line through the sphincter, dividing the anal canal posteriorly through its whole length and extending backwards to the coccyx. The loose tissue was then separated, and the upper end of the bowel found; this was then cleared as far as possible, care being taken to avoid opening the peritoneum, the reflections of which, from the sides and front of the bowel, could readily be demonstrated. The bowel was opened and sutured with fine catgut to the incision which had been made in the anal tube. The rest of the wound was then packed and dressed. The whole of the operation, from the making of the first incision to the application of the dressings, lasted ten minutes.

The child bore the operation well, and although convalescence was hindered by acute abscesses in the neck, no trouble was expected as a consequence of division of the sphincter when the patient leaves the hospital. The failure of urination was found to be, as suspected, an error of observation.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Obstetrical and Gynæcological Section.

Meeting held Thursday, February 13th, 1908.

The President, Dr. Herbert Spencer, in the Chair.

OVARIAN DERMOID WITH SECONDARY CYSTS CONNECTED WITH THE OMENTUM.

A paper on this subject was read by Dr. Martin Randall, including a pathological report by Mr. T. W. P. Lawrence. The author described the case of a young woman who had a pelvic tumour the size of a hen's egg situated in the right posterior quarter of the pelvis, rather high up. There were symptoms of inflammation, and the tumour was opened in the right iliac region, and purulent-looking fluid with some vernix-like material escaped. The cavity was drained, but subsequently the cyst was removed by operation. The omentum was observed to be studded with a large number of small cysts containing cheesy material and hair, and a large piece of this structure was removed. Mr. Lawrence reported that the main tumour was a dermoid of the right ovary. As many as fifty minute cysts were found in the omentum. They were for the most part lined with cubical epithelium and contained sebaceous material. The patient made a good recovery, but died a year later with symptoms of apoplexy.

The **President** (Dr. Herbert Spencer) thanked the authors for their valuable and interesting paper. He thought there was little doubt that the fluid at the first operation was sebaceous and not purulent. He had been surprised to find how frequently some operators met with "suppurating dermoids." The explanation he thought was that the sebaceous material, fluid at the temperature of the body closely resembled pus to the naked eye, although it solidified at a lower temperature. In his experience suppuration rarely occurred in dermoids. A practical deduction from the paper was the importance of removing these and other ovarian tumours entire, if they were not large. This had been his practice for many years. He did not go so far as Mr. Bland-Sutton, who removed all tumours, however large, entire, sometimes making an incision extending from the ensiform cartilage to the pubes; such a long incision certainly to some extent increased the risk of omental and intestinal adhesions and of hermia.

Dr. **Galabin** said that he had met with a somewhat similar case in which there had been a further development of the metastases than in any of these collected by Dr. Randall. An unmarried lady, aged between 40 and 50, came with a large tumour, the history of the duration of which was quite indefinite. She said that her abdomen had been large for as long as she could remember. An ovarian tumour was diagnosed. At the operation it turned out to be a dermoid and was removed with difficulty on account of universal adhesions. Among the adhesions and over the peritoneun were scattered very numerous thin-walled cysts containing sebaceous fluid like that in the main cyst. These existed also in the cellular tissue of the abdominal wall and pelvis, so that a number of them were divided in the abdominal incision. No skin-like structure was seen in the secondary cysts. Those on the peritoneum were thin-walled, but in the cellular tissue no definite cyst wall could be detected. A good deal of sebaceous matter had to be left unremoved, but the incision healed well in the first instance. After some weeks, however, it broke down again, and a discharge of oily fluid began, which later became semi-purulent. The patient remained ill many months, and it was feared the condition might run a malignant course, but eventually the sinus closed, she recovered completely, and was well after several years. He agreed with the President that it was desirable, if possible, to remove a small or medium-sized dermoid cyst entire.

Dr. R. H. **Hodgson** remarked on the fact that some of the cases had died with septic symptoms. He suggested that they might have been saved had hexamethylene-tetramine been used. He had experimented with it in large and small quantities in many and varied diseases, and had found it most valuable in septic diseases, but it needs to be used with great caution. The kidneys afford the first and most marked signs that the drug is in excess. He strongly suggests its use to those who have much operative work on the peritoneun.

Dr. H. **Macnaughton-Jones** said there must have been some thousands of ruptured dermoid cysts, and yet but the cases mentioned have been recorded. It did not appear, therefore, that there was any great danger of metastasis or implantation in the case of simple dermoids. No matter how extensive the incision, in some cases of dermoids, and with every case, rupture would occur.

The following specimens were exhibited:—

Dr. Herbert Spencer:—Caseating carcinoma of the corpus uteri.

Dr. H. Macnaughton-Jones :—Hæmato-salpinx complicating a myomatous uterus.

Dr. Eardley Holland :—A melanotic tumour of the vulva.

Dr. Amand Routh :—A placenta diffusa.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING HELD FRIDAY, JANUARY 31ST, 1908.

The President, J. M. REDMOND, in the Chair.

PROGNOSIS AND TREATMENT OF NEPHRITIS.

THE PRESIDENT of the Academy opened the discussion on the above subject by calling attention to the wide range of the subject and its vast importance in the realms of surgery and obstetrics as well as in medicine, and the interdependence of prognosis and treatment, so closely were they related to each other. He limited his remarks entirely to those inflammations included in the varieties—(*a*) acute nephritis due to toxic influences or exposure to cold ; (*b*) sub-acute or chronic parenchymatous nephritis ; and (*c*) chronic interstitial nephritis. He pointed out, however, that in every variety of nephritis there is more or less diffuse inflammation involving the glomeruli, the parenchyma, and the interstitial tissue. He then proceeded to discuss, with a view to forming a sure basis for prognosis and treatment, three principal features to be found in these cases—(1) Albuminuria, (2) dropsy, (3) the uræmic syndrome—and laid stress on the importance of taking a wide and comprehensive view of them, and of avoiding attaching too much significance to any one group by itself. On this point he called attention to the possible harm which may be done to a patient's prospects in life by rejecting him for insurance or admission to a post in the public services on account of albuminuria, pointing out that the condition may be due to adolescence or the result of temporary weakness of the heart. He indicated some errors to be avoided in this condition, such as testing a chance sample of urine instead of the water of 24 hours, the comparing of the albumin of one specimen with that of another when the variations may be entirely due to some change of diet or diminution of the liquids ingested ; and he quoted von Noorden's statement that "albumin is a conclusive index only in acute nephritis, as its reduction points to improvement, its increase to exacerbation." It is not so reliable in chronic parenchymatous nephritis, in which "it is liable to fluctuations, and an attempt to base a prognosis on or to estimate the effect of treatment by such a criterion is fallacious." On the other hand, their significance must never be under-rated when they point in the same direction as the other changes in the general condition of the patient. As to the possibility of treating albuminuria by medicine, he considered it was as little encouraging as in using hæmostatics in the hæmaturia of renal inflammation. The indications for treatment were to save the kidneys—to place them in physiological rest—by cutting off all proteid diet, as meats, soups, beef extracts, eggs, etc., by feeding the patient at first with starvation diet when the inflammation was acute, the urine bloody and very scanty, and then allowing a very restricted diet of milk and starchy foods, with cream and sugar. The amount of liquid permissible at first must not exceed two pints in 24 hours, as the oliguria is due to renal inefficiency, and it is as harmful as well as unscientific to try to produce diuresis by copious libations as it is by diuretic medicines. As soon, however, as the kidneys show recovery by secreting more water, it is then most beneficial to flush them with water, or lemon and water with a small quantity of cream of tartar. This treatment by deprivation of liquids is especially necessary when the oliguria is accompanied by dropsy, local or general. The second indication for the treatment of acute nephritis is to save the kidneys by calling the bowels and the skin into activity, and thereby eliminating the poisons and the water which the inefficiency of the renal epithelium causes to be retained. A daily morning dose of pulv. jalap co., or concentrated doses of magnesium sulph., will meet the one, and poulticing, leeching or cupping over the loins will effect the other. In some cases of acute nephritis where uræmic symptoms are early developed in a previously healthy and vigorous patient, it is right to bleed to 15-20 ozs. from the arm, or, as Baccelli suggests, from the dorsal vein of the foot. One such case was reported where venesection apparently saved the patient's life. In addition to local or general depletion, the use of hot air baths, hot pack, or hot baths was insisted on, and in most acute cases of albuminuria or of dropsy this treatment alone will be followed by diuresis. On the subject of anasarca, reference was made to the opinion of Straus, von Noorden and Senator as to the non-elimination by the secreting epithelium of the chlorides being one of its chief causes, and of the therapeusis of withholding salt from the diet, and to the statement of many German and French writers that the amount of dropsy can be gauged by the retention or the excretion of chlorides in parenchymatous nephritis, more especially when uræmic symptoms are present. This question does not arise in the chronic interstitial nephritis, as in it the chlorides are freely discharged. While the prognosis and treatment are more closely related to the state of the heart and the arteries, in these oft-times very chronic cases, lasting for years, the diet should be more generous and contain more proteids than in the other forms of kidney inflammation ; the prognosis as to cure is very bad, but much may be done to prolong life. The state of high tension of the arteries may be reduced and regulated by a systematic use of nitroglycerine, trinitrites or sodium nitrite for weeks and months, as under their use tension is reduced and the left ventricle is enabled to recover from a state of dilatation to the normal state of hypertrophy present in cirrhosis of the kidney. Should a case be complicated by an attack of acute nephritis, the treatment already detailed for that state must be used for a comparatively short time, and should uræmic headache or coma or convulsions set in, active treatment of the bowels and the skin should be instantly commenced and strenuously carried out, while full doses of chloral must be administered by mouth or rectum, and aided, if necessary, by inhalation of chloroform. Reference was made to the valuable effects of hypodermics of morphia in this form of disease, and when carefully administered and its effects watched, they will be found invaluable in stopping the convulsions, limiting the status epilepticus, relieving the headache, and arresting the vomiting. Another drug of great value is the iodide of potassium, which should be given for weeks and months at a time, since it diminishes the risks of hæmorrhage into the brain or retina, while, if bleeding has already taken place into the latter it causes its limitation and absorption.

PATHOLOGY OF NEPHRITIS.

Dr. **EARL** read a paper on the above subject. He confined his attention principally to three main points —(1) The etiology of nephritis ; (2) the classification of the varieties ; (3) the changes in the cardio-vascular system.

Dr. **TRAVERS SMITH** said it was a good thing to bear in mind that, taking a comprehensive view of the subject, nephritis was not altogether a destructive process. Nature did not stand by and allow the body to fall a victim to the disease without making a fight against it. She had two lines of defence. The first was high arterial tension and hypertrophy of the left ventricle, by which the kidneys had a greater supply of blood sent to them and more rapidly passed through them, this making up for some of the deficiency in the action of the kidney. The second line of defence was œdema, which, however they might regard it, took out of circulation certain toxic substances. Looking upon œdema—as well as upon high arterial tension—as conservative processes, he thought there were certain cases of extremely severe uræmic symptoms where it was a good thing to induce œdema. He had been struck on several occasions with patients who died of severe uræmic symptoms without ever having been in the least œdematous, and he thought that, if œdema be a conservative process, they might have been saved if they could have been made œdematous. He had given a man, who had been for some time in uræmic convulsions and coma, sodium chloride, with the result that at the end of 24 hours he became markedly œdematous, and made a good recovery from all his symptoms. He thought, therefore, that these two conservative processes should not be treated directly unless they were doing harm *per se*, and they should watch for cases in which the production of œdema might do good.

Sir **John Moore** said he concurred with the view put forward by Dr. Travers Smith as to the beneficial influence of œdema in cases of chronic renal disease, with regard to which he had read a paper before the British Medical Association at the Oxford meeting. The general view in regard to the pathology of nephritis was that increased arterial tension was the cause of the hypertrophy of the left ventricle of the heart, but recently the view had been put forward that the high arterial tension was the result of the forcible action of the heart caused by the circulation in the blood of an increased amount of nitrogenous compounds, such as urea and its allies. He could not go with Dr. Finny in dissenting from the view that water should be given freely in some forms of nephritis. He looked upon water as a valuable eliminant in cases of nephritis; it acted on the bowels and on the skin, and it was very desirable to keep the skin active in all forms of toxæmia, but the water should be soft water. They should not be too strict in dieting chronic nephritics; milk was sometimes very distasteful to them, and was not easily digested, and sometimes they died of starvation if kept off an animal diet. It was, moreover, just as necessary to treat nephritis in fresh air as tuberculosis.

Dr. **Finny**, in reply, said he did not take the view that œdema should be looked upon as a conservative process, when the materials which were stored up in the fluids in the cavities of the body were a constant danger of infection. It was well known that the presence of a great deal of dropsy might be compatible with good health, but it would hardly be looked upon as a conservative process saving the patients from some other danger. The subject, however, was open for consideration. High arterial tension was a compensating force, but at all times was a matter of great danger; at any moment there was the risk of rupture, and the treatment should really be to lower the tension.

HARVEIAN SOCIETY.

Meeting held Thursday, February 13th, 1908.

The President, Mr. D'Arcy Power, in the Chair.

Mr. **Maynard Smith** read a paper on

THE DIAGNOSIS AND TREATMENT OF ABDOMINAL INJURIES.

The symptoms resulting from these injuries were described in detail, and their relative importance in diagnosis was pointed out. The difficulty in distinguishing the general shock following the injury from the collapse associated with the rupture of an important abdominal organ, such as the liver or bowel, was fully dealt with. The signs associated with free fluid or gas in the peritoneal cavity were carefully discussed. The symptoms suggestive of a grave abdominal injury, such as the general appearance of illness of the patient, the increase in pulse rate, the presence of vomiting, and distension of the abdomen, were described, and the importance of noticing the advent of these at the earliest possible moment was insisted upon. The question of operative treatment was carefully considered. The whole paper was illustrated by the records of 124 consecutive cases of abdominal injury which had been under treatment at St. Mary's Hospital, and reasons for the views expressed and of the treatment advised in different abdominal injuries were in many cases supported by the results of these cases which formed the basis for the paper.

The paper was discussed by the President, Mr. Crisp English, Mr. Lawrence Jones, Dr. Aitken, Mr. Campbell Williams, and Dr. Spilsbury.

Dr. **Carmalt Jones** read a paper on

THE TREATMENT OF BRONCHIAL ASTHMA BY INOCULATION WITH A BACTERIAL VACCINE.

A brief review was given of the methods employed in the treatment of disease by the opsonic method. The method of the isolation of the organism, of its growth, the preparation of the vaccine, and the estimation of the quantity and frequency of the dose, by determination of the opsonic index of the patient after inoculation were fully described. In some cases of bronchial asthma a specific organism had been isolated from the sputum, and a vaccine prepared from this was used for inoculation of the patients suffering from the disease. Twenty severe cases of bronchial asthma were treated by the special vaccine prepared, and definite improvement occurred in 16 of these cases, a marked improvement in 11. The cases chosen were severe cases which had resisted the usual methods of treatment, and the patients themselves were convinced of the marked freedom from attacks, which they had experienced since undertaking treatment by inoculation. Dr. Carmalt Jones showed several of the cases which he had been treating.

The paper was discussed by the President and Dr. Willcox.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

The President, Dr. Walker Downie, in the Chair.

Dr. **Arnold Lorand**, of Carlsbad, delivered a very instructive and illuminating lecture on diabetes. His clinical researches were based on observations on over 700 cases of diabetes, and he had experimented on animals. According to Dr. Lorand, diabetes is brought about by morbid changes in the ductless glands, the thyroid, pancreas and adrenals. He pointed out that lesions in the brain very seldom give rise to true diabetes, although glycosuria is common. He maintained that Claude Bernard's famous puncture of the fourth ventricle of the brain gave rise only to glycosuria, and not to diabetes proper. He did not deny the influence of mental shock in producing diabetes. He thought it was a common cause, but it acted through its influence on the ductless glands. He pointed out analogies between Graves' disease and diabetes. Graves' disease was due to exaltation of the functions of the thyroid gland, and that when the gland atrophied, it was followed by myxœdema. Even in advanced cases of diabetes, myxœdematous symptoms may arise. The *rôle* of the liver he thought of secondary importance; that changes in that organ were secondary. Glycosuria could be distinguished from diabetes by a test meal of beef, rice and honey. Any very decided quantity of sugar in the urine indicated diabetes, but small quantities, like a half per cent., did not. In the genesis of diabetes he was strongly of opinion that large meat-eaters were specially prone to the disorder; indeed, a meal of meat and carbo-hydrate brought out the latent tendency to diabetes better than a purely meat or carbo-hydrate diet. Children of diabetics often showed their morbid tendency when tested in this way. Extirpation of the whole of the pancreas was followed by diabetes. In the treatment he advocated meat to be given once a day, and allowed a moderate quantity of carbo-hydrate. He allowed green vegetables and certain fruits like oranges and apples, also cream and sour milk. The great danger, he considered, in diabetes was not the sugar in the urine, but acetone and diacetic acid. He had found very beneficial effects from thyroid extract in removing diacetic acid from the urine. He thought the serum or milk of goats, whose thyroid had been extirpated, might prove of benefit. At all events, such milk had very decided soporific properties, and a dog living on such milk was practically useless, as it was always falling asleep.

An interesting demonstration of cases was given by the staff of the Glasgow Royal Infirmary to the members of the Glasgow Medico-Chirurgical Society.

Dr. T. K. **Monro** showed a patient suffering from syphilis of the nervous system, and an Icelandic fisherman who was recovering from an attack of beri-beri associated with a cutaneous eruption.

Dr. **Cowan** exhibited a patient suffering from syringo-myelia; casts from a case of aero-megaly; and a series of blood charts.

Dr. **Harrington** showed microscopical specimens of the blood from a case of pernicious anæmia; the irregular size of the corpuscles was very evident; and the hæmoglobin index was high.

Dr. **Hunter** showed a case of Banti's disease.

Dr. **M. Crorie** and Dr. **Campbell** gave a magnificent demonstration of micro-organisms. Beautiful specimens of the parasite of sleeping sickness, ague, filaria sanguinis hominis, bacillus pestis, the coccus rheumaticus, leprosy, and many others.

Dr. **James R. Riddell** showed 15 patients. Several were cases of lupus vulgaris healed, and others in the process of healing; two cases of tubercular disease in bone which had got well; one case of keloid also healed; two cases of exophthalmic goître, both of which were greatly improved; in one case the improvement had been maintained, and the treatment had been stopped for a year; the pulse had dropped from 109 to 80. The exophthalmos was much less, and all symptoms had practically disappeared. Two cases of rodent ulcer, one healed and one almost well; all these had been treated by X-rays. In the cases of goître, X-rays were used on account of their known power of destroying epithelial tissue and their degenerating action on glandular structures. One case of rodent ulcer was shown illustrating the use of ionised zinc; the ulcer, which had been rather larger than a shilling, was completely healed. Three cases were shown illustrating the beneficial action of X-rays, which may sometimes be got in the more serious forms of malignant disease; one patient had a recurrence of cancer in the scar after removal of the breast. This case had come under treatment in November of 1904, at that time there was an ulcer on the scar about the position of the nipple the size of a crown piece, pain and hæmorrhage were prominent symptoms; there were six or seven small red nodules on the skin scattered along the edge of the scar, and in the axilla was a mass, not well defined, about the size of a pigeon's egg or less. In three months time the ulcer had quite healed, the axillary mass was practically gone, as had also most of the nodules in the skin. The œdema in the arm, which had been a marked feature, was much less. Patient had occasional treatment chiefly to axilla until early in 1906, when treatment was suspended altogether. Lately the axillary mass has increased, and treatment is resumed. The second was a case of epithelioma on the dorsum of the foot. A small tumour had appeared in January, 1907. It had enlarged and broken down, leaving an ulcerating mass the size of a florin. Treatment began in November, and by this date the ulceration was entirely healed and the tumour gone. The third case was one of round-celled sarcoma in the naso-pharynx. Towards the end of 1903 the patient began to have a discharge from the nose. In a few months his nose became blocked, and blood was occasionally present in the discharge. Headaches, sleeplessness, and progressive loss of weight were present. Treatment began on June 7th, 1904, when patient's weight had fallen to 8 st. 2 lbs. By January, 1905, the tumour had disappeared entirely. Sixty applications had been made, and the patient had put on about 2 st. weight. At this date, after three years, the naso-pharynx appears quite normal. Among other appliances those for producing temporary complete epilation by one measured dose of X-rays (for treating ringworm, etc.) for ionisation, for exact localisation, a stereoscope for radiograms, etc., were shown, as were also radiograms illustrating fractures, dislocations. Early tubercular disease in lungs and bones, abscess of bone, cancer of bone, the examination of the bowel after a bismuth meal, urinary calculi, etc., etc.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held Thursday, February 13th, 1908.

The President, Mr. T. H. **Bickerton**, in the Chair.

Dr. **Crace-Calvert** read a note on

THE TREATMENT OF HÆMOPTYSIS BY NITRITE OF AMYL.

He stated that till recently the treatment of hæmoptysis had not been satisfactory, and that nearly all drugs except morphia had been described as useless. Dr. F. W. E. Hare had called attention to the use of the nitrite in checking hæmorrhage, and pointed out that it acted partly by causing a marked reduction in the arterial blood pressure, and partly by producing an intense anæmia of the lung parenchyma, and so gave time for clotting to take place. Dr. Crace-Calvert had tried it in about 25 attacks of hæmoptysis—many of them profuse—and always found that it checked the bleeding almost instantly. Afterwards, if there were excitement of any kind, he gave a quarter of a grain of morphia. He considered that nitrite of amyl was the drug *par excellence* to be used first, as it saved the patient unnecessary loss of blood, and prevented large accumulations of blood in the air-passages. It was especially useful in sanatorium work, where the patient was seen at the beginning of the attack.

Sir **James Barr** congratulated Dr. Crace-Calvert for pointing out the value to be obtained from the use of nitrite of amyl, and such other agents in cases of hæmoptysis. We often hear of blood pressure in numerous diseases without the observers having any clear idea as to what is meant by blood pressure. Is it arterial pressure, capillary pressure, venous pressure, or the pressure within the arterioles? Those who talk so glibly on the subject generally mean arterial pressure, and in this case the reference must be to the systemic arterial system, because the pulmonic system is very poorly supplied with any regulative mechanism in the form of vasomotor nerves, and damming back of the blood in the pulmonic system must be due to heightened pressure within the arterial system. Blood pressure is purely a relative term, and what might be considered a very high blood pressure in phthisis would be a low pressure in renal disease. In phthisis the heart is small and weak, and a comparatively small resistance is more than it can cope with; therefore, any slight rise in the arterial pressure in cases of phthisis is very apt to dam back the blood in the pulmonic system. The great advantage of the use of morphia, or morphia and atropine, in cases of phthisis, arises from the fact that they generally stop the cough, and thus prevent any rise in the arterial pressure. Personally, he has for many years used nitro-glycerine in cases of hæmoptysis, and, as a rule, he prefers it to nitrite of amyl because of its more lasting effect. If the blood is deficient in lime salts, it is very important that lime salts should be administered.

Dr. **Nathan Raw** could not agree that nitrite of amyl had any specific action in the control of hæmoptysis. Whilst one occasionally met with an overpowering hæmorrhage which was rapidly fatal, the fact remains that the great majority subside spontaneously with care and rest. He could not agree that hæmoptysis was due to increased blood pressure, but rather to erosion of some small blood vessel. He advocated absolute rest in the recumbent posture, a hypodermic of morphia, ice to suck, and cold turpentine applications to the chest. He had seen excellent results from adrenalin chloride in long-continued but small hæmorrhages from the lungs. By lowering the blood pressure it was possible that nitrite of amyl was occasionally useful.

Dr. **W. B. Warrington** said it had long been recognised that a hypodermic injection of morphia was the most satisfactory drug in the treatment of hæmoptysis, and for some years past nitrite of amyl, in addition, had been the routine treatment at the Northern Hospital.

Dr. **A. G. Gullan** said that there seemed to be varied opinions on the blood pressure of phthisis, and he believed that in many cases it was lowered. Yet everyone was well acquainted with the excited and strong action of the heart and the strong and quick pulse, which arose on the sudden occurrence of a serious hæmoptysis. The arterial blood pressure was then undoubtedly greatly increased, and it was in this condition that the amyl nitrite was beneficial as a rapid means of lowering it. At the same time such good results had been obtained by rest, morphia, and purgatives in the past, and, moreover, these methods were invariably used in conjunction with amyl nitrite, that he felt too much credit for the good results obtained should not be given to that drug.

Dr. **R. J. M. Buchanan** drew attention to the fact that cases of phthisis associated with good blood pressure generally did well, and that hæmoptysis more often occurred in chronic and relatively favourable cases. The hæmoptysis was in a large majority of cases the result of raised blood pressure in the systemic arteries, and Nature pointed out a method of treatment in that the hæmoptysis itself lowered pressure, and thus arrested hæmorrhage. Taking the lesson from Nature, the use of nitrite of amyl, acting in the same way, was a rational therapeutic measure, and the results justified its administration. Dr. Buchanan advised a course of sodium nitrite afterwards to prevent recurrence at any time when from a marked rise of pressure hæmoptysis was to be feared. He did not advocate worrying the patient at the time of the hæmorrhage with purgatives. Dr. Buchanan related a case of recurrent hæmoptysis without any pulmonary lesion always associated with high blood pressure due to tobacco smoking, and always arrested by the exhibition of nitro-glycerine and nitrite of soda.

The note was also discussed by the President, Drs. Bushby, Bradshaw, and Abram, and Dr. Crace-Calvert replied.

Dr. W. **Blair Bell** read a paper on

SOME OBSERVATIONS ON THE PHYSIOLOGICAL IMPORTANCE OF THE CALCIUM SALTS.

These observations which had been made incidentally during the work he is at present engaged upon in reference to the calcium metabolism in menstruation and pregnancy, he considered of sufficient importance to bring forward, as he himself could not carry them any further. His method of calcium estimation, described in the *British Medical Journal* for April 20th last, had been largely employed in the investigation. The diurnal variations and the value to be attached to the blood index and the interpretation thereof were fully described. He discussed what he described as the reparative function of calcium salts, and stated that he considered there was always a determination of these salts to an injured or a diseased region. He also thought that there was no such thing as calcareous degeneration *per se*, but rather calcification—a reparative process—in diseased structures. The effect lime salts had upon involuntary muscles was next mentioned, and Dr. Blair Bell alluded to the work of Ringer and others in this direction. He went on to describe the attempts made by himself to discover the regulating factors in the calcium metabolism, and discussed his experiments and observations in regard to the thyroid, pituitary, and other ductless glands, which he considered acted in association, anabolically or catabolically, in connection with the lime salts. The question of calcium and the coagulability of the blood was discussed, and he brought forward evidence to show that the reduction of the coagulability of the blood on the administration of an excess of lime salt was due, not to an excess in the blood, but to an active resistance or immunity on the part of the subject, or increased excretion brought about probably by thyroid interference. The power the leucocytes possess of absorbing calcium probably in solution, and conveying it for the processes of repair and for other functions, was considered, and evidence adduced to show the probability of this property. Lastly, Dr. Blair Bell described some interesting observations upon gelatin and the contained calcium. He illustrated the fact which he had discovered, that if calcium is precipitated from gelatin, it will no longer coagulate by passing round a control and a specimen prepared several days before.

Sir **James Barr** said that he considered this one of the most important papers that he had heard for a long time. He has himself been using calcium in disease for many years, and therefore feels very grateful to Dr. Blair Bell for giving a more accurate method for estimating the amount of calcium in the blood. Hitherto, we have had to go by the coagulability of the blood, and in such a disease as pneumonia by the amount of the adhesiveness of the secretion. In cases of pneumonia it has a very great value, especially in those cases in which the secretion is liquid or hæmorrhagic. *Cæteris paribus*, the more scanty and viscid the expectoration in pneumonia the better the prognosis, hence in such a disease he had condemned the use of expectorants for many years. The calcium salts have a wonderful effect, not only in increasing the secretion, but in toning up the vessels. The variable amount of lime salts in the blood at different periods of the day scarcely affects the diseased conditions, because in the infective process the calcium is thrown out of the blood into the tissues, and in such cases there was always a tendency to a deficiency. The important effect of the calcium salts in maintaining the heart's action has been well-known since the observations of Sidney Ringer. The reparative action of the calcium salts has been shown by Dr. Blair Bell, but in many chronic diseases they are apt to accumulate in the blood where there is defective excretion, and become deposited in the walls of the vessels. Now, although the salts under these circumstances are fairly insoluble, yet by maintaining a high alkalinity of the blood by the use of citrates these salts can be withdrawn from the tissues. The observation of Dr. Blair Bell on the presence of calcium in the leucocytes is exceedingly interesting. The great increase in the blood of a cat where the thyroid had been removed was interesting, because Sir James Barr has found that in cases of exophthalmic goître the lime salts are nearly always defective, and great amelioration of the symptoms can be produced by their administration. He hoped that Dr. Blair Bell would pursue his interesting investigations by which the profession generally will derive much benefit.

Dr. R. J. M. **Buchanan** considered Dr. Blair Bell's method of calcimetry by the use of the hæmocytometer sufficiently accurate for clinical purposes, and stood on a par with erythrocytometry and leucocytometry in abnormal blood states.

Dr. P. **Hick** said that although the total calcium of the blood was not precipitated by Dr. Blair Bell's method, all the "ionised" calcium was, and that it was in this state that the calcium took part in such active processes as the clotting of blood, and the method gave a measure of the available calcium. Also that calcium chloride and calcium lactate given by the mouth occasionally gave no rise in the calcium content of the blood, which seemed to show that in these cases inorganic Ca salts or the Ca salts of the simpler organic acids were not capable of absorption. Sir A. E. Wright having previously arrived at the same conclusion, by showing that these salts so administered in such cases produced no increase in the coagulability of the blood, Dr. Hick suggested that the disappointing results obtained with gelatin by some observers were due to using only a 2 per cent. solution which contained only a comparatively small amount of gelatin.

Dr. **Gordon Little**, whilst endorsing the remarks as to the interesting character of the paper, emphasised the necessity for verification of the method employed by strict chemical analysis. It was absolutely necessary that clinicians should exercise the greatest care, especially when they attempted work in the domain of physiological or physical chemistry. In the past, objection had been taken—and rightly taken—by high authorities to the unreliable methods by which some eminent authors had obtained their results, and upon which far-reaching theories had been set up, only to be discounted later. He pointed out that the method of Dr. Blair Bell was a comparative method, and that by it only a proportion of the calcium in the blood could be estimated—viz., the free or ionised calcium. There was, in addition, the masked or absorbed calcium in combination with proteins which this method did not touch, and which in a metabolic sense was the most important. He also drew attention to the artificial standard of comparison and the impossibility of measuring by means of crystals formed in an aqueous solution, even of known strength, those formed in a complex colloidal medium such as blood. The process of crystallisation went on in the two media under totally different conditions. Attention was called to Dr. Blair Bell's results in reference to reconstruction and the diminished calcium content of the blood during that period, as illustrating the relationship of calcium to gout. It might tend to explain why women suffered less frequently from the disease than men. He also pointed out that, owing to the frequent variations that went on almost from hour to hour, the idea of establishing a so-called "calcium index" was next to impossible, without any prolonged series of observations. He also remarked that the subject of calcium was not so new as had been suggested. As an empiric remedy it was among the oldest and best authenticated, as in the waters of well-known springs—*e.g.*, Contrexéville, Buxton and Bath—and mentioned the names of modern workers, especially Ringer in this country and McCallum in America, who, with a number of others, had done much to prove the importance of this element in the human economy. In regard to calcium as a factor in the setting of gelatin, its essential importance was disputed. Reference was made to a paper by Mörner, in the *Zeit. fur Physiolog. Chemie.* (28, p. 471, 1899) on the coagulation of gelatin. Mörner showed that ash-free preparations of gelatin show very little difference in the time of coagulation when formed into aqueous solution as compared with ordinary gelatin containing 0.4—3.1 per cent. of ash, and as the result of a long series of well-conducted experiments states:—"Solutions of gelatin rich in ash do not in the very least surpass the solutions of ash-free gelatin preparations in regard to ease with which they coagulate," and further shows that the addition of neutral salts greatly increases the time required for the coagulation of gelatin solutions, although this is in no way due to a chemical change, but is purely a physical effect.

The President discussed the paper, and Dr. Blair Bell replied.

CORRESPONDENCE

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Feb. 23rd, 1908.

CANCER OF THE STOMACH.

THE medical treatment of gastric cancer cannot, naturally, be otherwise than palliative, but, when intelligently applied, it can prolong life to almost the same extent as that obtained by surgical interference without exposing the patient, as in the case of operation, to death in a third of the cases.

Certain drugs have been supposed to possess certain anti-cancerous virtues. Although such is not, unfortunately, the case, they render good therapeutic service, says Prof. Robin, a well-known authority on disease of the stomach.

Leaving aside the different anti-cancerous serums so much vaunted in past years, it is well to study those agents of which the palliative effect is certain.

Condurango gave to Friedreich excellent results that were not obtained by other authors. In reality it is a good tonic, and can be prescribed under the form of tincture, 10 drops before meals, or as follows:—

Condurango bark (white), ½ oz.
Water, 10 oz.

Reduce by boiling to 6 oz. A tablespoonful half an hour before each meal.

Chlorate of soda, recommended by Brissaud, only temporarily improves the appetite. Albuminuria constitutes a counter-indication.

Fressenger proposed some years ago the treatment with bihydrochlorate of quinine. Although it does not possess more curative value than the preceding drugs, it retards notably the development of the disease and improves some of the symptoms. It can be given by the mouth, the rectum, or hypodermically. By the mouth it fatigues the stomach, by the rectum it produces tenesmus, and under the skin it is sometimes painful. Prof. Robin alternates the three methods in the folowing manner: During eight days he injects beneath the skin of the epigastrium the contents of one and finally two hypodermic syringes of the following solution:—

Bihydrochlorate of quinine, 6½ dr.
Sterilised water, 14 dr.

The following eight days he gives in a wafer 10 grains of the quinine fasting, and the same amount in the evening as a suppository, when he returns to the injections, and so on.

Two drugs help the action of the quinine salts—methyl arseniate of soda and bromide of gold. The arrhenal is given in 5 per cent. solution at the dose of 10 drops twice a day during five days. During five days more a tablespoonful of the bromide of gold solution—

Bromide of gold, 1 gr.
Water, 10 oz.

As to the *régime* which materially aids the treatment, it depends on the tolerance of the stomach. Generally the milk diet alone is prescribed, but there are some patients who cannot support milk. However, in cases of pyloric stenosis, hæmatemesis, or an insurmountable repugnance for food of any kind, milk alone is tolerated. In all other cases the patients can and ought to eat, but the *régime* must be regulated according to the condition of the intestines. If there is diarrhœa, meat must be suppressed and vegetables alone allowed; otherwise a mixed diet adapted to the capacity of the stomach may be prescribed.

But, in order that the patient should eat, he must be given an appetite, and here persulphate of soda succeeds admirably—

Persulphate of soda, 30 gr.
Water, 10 oz.

A tablespoonful half an hour before the two principal repasts.

Metavanadate of soda acts similarly—

Metavanadate of soda, ½ gr.
Water, 12 oz.

A tablespoonful half an hour before meals.

When the patient has eaten, digestion must be facilitated by hydrochloric acid and digestive ferments—

Hydrochloric acid, 35 drops.
Water, 1 quart.

A wineglass or more to be drunk during the meal. In the midde of the repast one of the following wafers—

Pepsin, 15 gr.
Maltine, 2 gr.

After the meal, two pills of pancreatin (2 gr. each).

Fermentation will be treated by fluoride of ammonium—

Fluoride of ammonium, 5 gr.
Water, 10 oz.

A tablespoonful towards the middle of the repast.

If the flatulence causes more or less pain, the following mixture may be prescribed:—

Subnitrate of bismuth, 1 dr.
Phenic acid 15 drops.
Spirits of chloroform, 2 dr.
Water, 4 oz.

If the suffering is intense:—

Cocain, 1 gr.
Codeine, 1 gr.
Lime water, 5 oz.
Spirits of chloroform, 2 dr.
Water, 5 oz.
A teaspoonful after meals.

The substitution of milk diet for the diet that had been allowed alternates the pain by diminishing the irritation produced by the food on the gastric mucous membrane.

It relieves also the vomiting, which can also be checked by giving before each absorption of milk 4 or 5 drops of the following mixture:—

Picrotoxin, 1 gr.
Proof spirit to dissolve, q.s.
Hydrochl. of morphia, 1 gr.
Atropine, 1-6th gr.
Ergotin, 15 gr.
Cherry laurel water, 3 dr.

If the gastric intolerance is absolute, recourse should be had to nutritive enemata.

Such is the treatment recommended by Prof. Robin, and if the lives of the patients are not prolonged very much, it at least relieves their sufferings and allows them to entertain more or less hope. It is only where relief cannot be obtained by medical means that gastro-enterostomy is justifiable.

GERMANY.

Berlin, Feb. 23rd, 1908.

AT the Medizinische Gesellschaft, Hr. E. Klebs gave a report on some

EXPERIMENTS WITH BLINDWORM TUBERCLE BACILLI —*i.e.*, tubercle bacilli that had had their origin in the human subject, but had passed through the body of the blindworm. From these he made pure cultivations. He injected equal quantities of sputum containing tubercle bacilli into the anterior chambers of both eyes of rabbits. An emulsion of the culture bacilli was injected afterwards into the left orbit of the rabbits. The left eye at first remained sound, whilst the right eye was soon destroyed by tuberculous panophthalmitis. It was only after an interval that a white nodule formed slowly on the iris of the left eye. The speaker further took sputum containing tubercle bacilli, mixed it with the blindworm bacilli, and placed the mixture in the incubation chamber for three days. He injected some of this mixture likewise into the anterior chamber of a rabbit's eye, and obtained nothing from it but a staphyloma of the cornea, which only appeared after the lapse of 40 days. There appeared, therefore, to be an antagonism between human bacilli and those of cold-blooded animals, which was the more remarkable, as the blindworm bacilli originated in the human subject, and only had their biological characters changed by passing through the body of the blindworm.

Hr. Sticker showed

A Tumour of the Brain of a Dog Experimentally Produced.

He had trepanned the skull of a dog, and had implanted a remnant of round-celled sarcoma, frequently used by him, into the left posterior lobe of the brain. After this the dog remained well for a long time; no visible changes were seen even in the fundus oculi. Convulsions first appeared on the 163rd day, then maniacal movements, and afterwards a deep sleep; the following day there were ataxic movements, a condition of sopor and death. The tumour was the size of a cherry.

Hr. Borchardt showed

A Student, Æt. 24, from whom he had Removed the Talus

five years before for sarcoma. In 1901 he was unsuccessfully treated for tuberculous disease of the ankle-joint, until, two years later, Röntgen illumination showed a tumour of the talus. This proved to be a giant-celled sarcoma. The patient had been permanently cured by the operation, and could walk as with a normal foot. It was the first reported case of permanent cure of sarcoma by conservative treatment, without amputation.

Discussion on Hr. Casper's Paper on Recurrences of Papilloma of the Bladder.

Hr. Mankiewicz alluded to the similarity between papilloma of the urinary tract and the same disease in the respiratory tract, particularly the larynx. Here recurrences were seen after intra-laryngeal operations as well as after laryngotomy. It had been thought that a malignant metaplasia might take place after operation, but the attempt to prove this had failed. He mentioned the case of a patient who had suffered from vesical hæmorrhage for two years, and had also two papillomata at the orifice of the ureters. The patient declined operation. When the speaker saw him two years later the growths had entirely disappeared. Spontaneous cures of papillomata did take place, therefore, even if rarely. It was equally certain that papillæ existed in the normal individual in a certain number of cases, the precursors of papilloma.

He next referred to the distinguished effects of arsenic on papillomata, and suggested its use in bladder affections.

Hr. M. Borchardt had removed quite a number of papillomata of the bladder by the high operation, but had seen no recurrences. Even conceding that a certain number of his patients had gone elsewhere, the number must still be small. Where recurrences did take place, some very small ones were probably overlooked. A great deal could be said in favour of the high operation as regarded certainty of diagnosis and completeness of the operation.

Hr. Sticker referred to the papillomata of dogs that had a malignant nucleus, and suggested that in the cases in which recurrences took place, small ones could easily be overlooked.

Hr. Israel summarised the discussion, and afterwards reverted to the case of the patient that Casper had made the basis for his paper. This man had suffered from vesical hæmorrhage for 12 years before he came to himself (the speaker), and in 9½ years he had then been operated on by Nitze nearly 60 times, and he had been repeatedly admitted into hospital for serious hæmorrhage. The value of intra-vesical operation should not be over-estimated, therefore.

In his reply, Hr. Casper mentioned a tenth case that had come under his notice of a man who had already had the high operation performed four times, with recurrences constantly taking place. The endo-vesical was a less serious operation, and the general condition was but little affected by it, and death had never taken place from hæmorrhage. If the bleeding would not stop, the sectio alta could still be carried out as before.

AUSTRIA.

Vienna, Feb. 23rd, 1908.

Lymphatic Leucocythæmia and Chylothorax.

At the "Gesellschaft für Innere Medizin," Strasser presented a patient who had been brought to hospital for weakness, diarrhœa, and general debility with enlarged glands. On February 4th, 1907, her report is: Cachexia, glandular enlargement of neck, axillæ and groin, while the spleen projected three finger breadths below the ribs, associated with stertorous breathing, enlargement of abdomen, and firm resistance over the epigastrum, with the feeling of a distinct tumour in the umbilical region with an irregular surface. The erythrocytes were 4,000,000, leucocytes 43,700, hæmoglobin (Fleischl) 74 per cent. The white corpuscles contain 0.5 of polynuclear cells. The Röntgen rays were applied, and improved the blood considerably, but the lymphocytes still remained abnormally high. The spleen receded below the margin of the ribs, while the other lymphatic glands were decidedly reduced, but the hard tumour in the umbilical region remained unchanged. In July the patient complained of great pressure in the thorax, associated with shortness of breath. Closer examination revealed dulness on the right posterior surface of the thorax, about 9 ctms. above the fourth rib. Respiratory breathing and pectoral fremitus were quite absent over this region, but the tumour in the abdomen was unchanged, and the margin of the liver could not be defined. The leucocytes were now 2,500 and the hæmoglobin 70 per cent. It was resolved to continue the Röntgen rays, which were applied constantly till the beginning of November when the leucocytes were then found to be 5,930, of which 15.5 per cent. were polynuclear, while the exudation in the chest had increased with the dyspnœa. The right side was aspirated, and 2,000 grammes of a white milky hæmogenous fluid was extracted, which was found to be chylous.

Three weeks later 2,400 grammes were drawn off, and the analysis gave the same chylous result. After the second aspiration the fluid was longer in collecting, and the third extraction was performed the day before the patient was presented, and 1,000 grammes of the same fluid were drawn off.

The etiology of the case is somewhat enigmatical, but the chylothorax appears to be due to the compression and subsequent bursting of the ductus thoracicus, probably the result of the sarcomatous growth in the abdomen.

Decastello applied the Röntgen rays to this case, and affirms that the radiation of the long bones had no effect on the blood pressure. After radiating the lymphatics and spleen there was a sudden fall in the number of leucocytes, which within one week fell from 402,000 to 127,000, and after a month to 51,000.

Offer remarked that the fluid extracted gave Ehrmann's reaction, *i.e.*, one cubic centimetre of the fluid counteracted 0.01 of a mg. of adrenalin when applied to a dilated pupil.

Strasser remarked that the tests for glycosuria were negative.

Epiploitis.

Reitter showed a case he had to operate on after herniotomy for epiploitis five weeks after the first operation. The patient suffered for some time from bilateral inguinal hernia, which was successfully corrected, but five weeks after fever, pain, swelling, and fluctuation indicated some recurrence. After warm applications and rest the tumour, about the size of a child's head, was opened, and found to be an inflammation of the epiploica, which had been caught in the stitches when closing the herniotomy.

Tubercle in Brain.

Flesh presented a patient in whom he diagnosed tubercle in the right pedicle of the brain. There was tubercle in the apex of the left lung, with Calmette's reaction of the conjunctiva after 24 hours.

There was spastic alternating hemiparesis with the characteristic paralysis of the oculomotorius. This combination pointed to a lesion in the right peduncle. This form of paralysis has gone under the name of Weber's paralysis or hemiplegia alterans superior since 1863. The lesion in the lung is excellent confirmation in this case.

ALGIERS.

Mustapha Superieur, Feb., 1908.

So many places have sprung into existence of late whose promoters have placed in the forefront very extravagant claims for the patronage of English physicians, their patients, and the travelling public, that it is somewhat difficult to describe the special attractions of an ancient town like Algiers within modest proportions. It is, however, too well-known to need reference here to its past history, and I will therefore refer briefly to it as it affects the profession in search of a change for health's sake for themselves or their patients, and the impressions made on a stranger like myself visiting it for the first time during the present month in search of that necessity of life—health. The first thing that occurred to me was the absolute serenity of its atmosphere, the extraordinary distances the eye could compass, and the cloudless African sky.

Hemmed in, as Algiers is, by a horseshoe range of hills, the climate appears to be comparatively uniform, and one does not experience that sudden drop of temperature at sunset which is peculiar to many of the Mediterranean stations. The air is of that balmy sweetness which is so soothing to jaded nerves on a fine May morning in England, and should prove of signal service during the winter months to those predisposed to pulmonary affections, cardiac or renal troubles. Rheumatic subjects should also do particularly well there, inasmuch as they can safely spend nearly the whole day in the open air under an unclouded sun. I have not as yet seen rain, but am informed that the rainfall averages about the same as in Paris or London, but that, when it descends, it is much heavier, and therefore shorter in duration.

Mustapha Supérieur, situated on the upper slopes, amid an environment of orange, lemon, olive and palm trees, is the residential quarter of Algiers, whereat reside one or two English and several eminent French physicians (on some of whose tables I was glad to see copies of The Medical Press and Circular). There is a large civil as well as a military hospital, and a cottage hospital for British subjects. On behalf of the latter a bazaar is being held this week under the patronage of H.R.H. Princess Beatrice (Princess Henry of Battenberg), who has been staying with her son for some months past at the Hotel Continental. Algiers cannot boast of the palatial hotels that are found along the Riviera. All are comparatively small, but home-like and comfortable, the principal being, in addition to the Continental, the St. George, the Alexandra, and the Oriental, all at Mustapha Supérieur, and the Hotel de la Regence and the Excelsior down in the town.

Those whose soul is accessible to the picturesque will find here in the Arab quarters thousands of Moors, Kabyles, Jews, and other native races, whose splendour and misery afford much food for contemplation; whilst lovers of art will find their leisure fully absorbed in the study of ancient monuments of Algerian grandeur, and the present attempts at modern greatness.

There are, of course, many ways of getting to Algiers, the quickest from England being the overland route by the P.L.M. lines through Paris to Marseilles, thence by Transatlantique Company's steamer (25 hours) to Algiers; but to those for whom the sea has no terrors, I would advise the voyage from London to Marseilles by one of the magnificent floating palaces of the P. and O. Company. These are so huge that, even in rough weather, motion is greatly minimised, and any tendency to sea-sickness lessened thereby. As to the health-giving properties of "life on the ocean wave," I need not here refer, and the pleasure of a call at Gibraltar will decidedly enhance the pleasure of a sea voyage.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Appointment of Dr. Clouston's Successor.—The directors of the Royal Edinburgh Asylum have appointed Dr. George M. Robertson, M.B., C.M., F.R.C.P., Superintendent of the Stirling District Asylum, Larbert, to be Superintendent of Morningside Asylum. Dr. Robertson's whole professional career has been devoted to work in connection with mental diseases. He was for six years an Assistant Physician at Morningside, under Dr. Clouston, whence he was promoted to be Superintendent of Murthly Asylum. In 1899, on the appointment of Dr. John Macpherson to a Commissionership in Lunacy, Dr. Robertson succeeded him at Larbert. His tenure of office there has in every way been an unqualified success. He is an excellent organiser, and has effected large economies in the management of the institution, while at the same time the general standard of comfort throughout the Asylum has been raised. His chief work, however, has been in connection with the introduction of improvements in nursing. In place of the old system of charge attendants, he has succeeded in placing the nursing of the patients, both male and female, under the control of fully-trained hospital nurses. His system of nursing has attracted much attention among alienists, and his example has been followed in several quarters, while Larbert Asylum has been visited by many American and Continental experts desirous of seeing for themselves the details of the admirable system of nursing in operation there. Though his principal strength is as an administrator, Dr. Robertson has not neglected the scientific aspects of insanity. Within late years he has equipped a laboratory in connection with the Asylum, and has secured the appointment to the staff of the Asylum of a trained bacteriologist, by whom investigations are being made on the etiology of general paralysis and the acuter forms of insanity. Dr. Robertson has had considerable experience in teaching students, having for eight years been a Lecturer on Mental Diseases in the School of Medicine of the Royal Colleges. He was employed by the Edinburgh District Lunacy Board as medical expert to report on the plans of the village Asylum at Bangour.

Infant Life Protection Act.—A case which well illustrates the inadequacy of the legislation concerning boarding-out of infants was tried last week before Sheriff Mackenzie, Glasgow. A midwife named Russell was indicted under the Act for having on four occasions failed to report to the authorities that she had received into her custody children for whom she had been paid money. The Criminal Officer to Glasgow Parish Council testified that when he visited the accused in March, 1907, she denied receiving infants for adoption. Towards the end of December he received information that prisoner had adopted a child named Davidson. By that time prisoner had changed her residence, and in her new house two children had been born and died. The Parish Council did not receive notice of the deaths as required by the Act. The accused was apprehended on board an American liner bound for New York, having taken a passage under a false name. Evidence was given by four young mothers as to the handing over of their infants to the accused, and the payment of money—from £5 to £7—on the understanding that homes were to be found for them. The Sheriff found the respondent liable to forfeit the four sums received by her, with the alternative of 21 days' imprisonment for each offence. She was also fined £10 for having failed to notify the Procurator-Fiscal of the deaths of two of the children under her care. A case such as this, involving the deaths of four young infants, strongly enforces the necessity for further legislation, and the more effective supervision of persons carrying on the practice of adopting infants for gain.

British Medical Association.—The usual conjoint meeting of the Scottish branches was held in the Royal Infirmary, Edinburgh, on February 21st, when a long programme was successfully carried through. A large number of instructive cases were exhibited, among which may be mentioned Dr. F. Gardiner's patients suffering from sycosis and furunculosis illustrating the vaccine treatment of these diseases; fracture of the patella treated under lumbar anæsthesia with tropacocain, and removal of half of a tongue, division and wiring of the jaw under local anæsthesia (cocain), shown by Mr. Caird; a patient, æt. 3, suffering from epispadias with incontinence treated by transplantation of the ureters into the pelvic colon. There is now no incontinence; the urine is almost clear, and generally passed independently of the fæces. This patient was shown by Mr. Stiles, who also demonstrated (1) a child of 15 months two months after operation for a complete branchial fistula. A silkworm gut suture introduced into the external opening could be passed upwards until it finally emerged through the nostril of the corresponding side. (2) A male, æt. 36, after pylorectomy for a sarcomatous tumour of the muscular coat. The condition found at the operation reminded one of congenital hypertrophy of the pylorus. (3) A child, æt. 5, operated on for obstruction at the pylorus was also shown; the condition here, also, resembled that of congenital hypertrophy of the pylorus. Dr. Fleming showed a case of spastic diplegia with athetoid movements occurring in a man of 43. Mr. Cathcart, among other surgical cases, one of colostomy for idiopathic dilatation of the colon. Dr. Chalmers Watson showed a series of cases illustrating the features of chronic inflammatory or degenerative changes in the pancreas, demonstrating the clinical value of Cammage's pancreatic reaction. Mr. Scot Skirving showed several cases of surgical interest, including one of the now rare disease—popliteal aneurysm, treated by excision of the sac. Dr. Russell showed a case of filaria loa, and others. Dr. John Thomson showed a case of congenital obstruction of the bile duct, an early case of pseudo-hypertrophic paralysis with wasting of the pectorals, and to contrast with this a case of congenital defect of the pectoral muscles. Patients were also shown by Dr. Edwin Bramwell, Dr. Sinclair, Mr. Miles, Mr. George Chiene, Dr. Thompson, Dr. Dunlop, Dr. Cairnhill, Dr. Low, and Dr. Byrom Bramwell. Another feature of the meeting was the museum, in which Dr. Low's beautiful exhibit of casts of skin diseases, Dr. Lauder Thomson's exhibit of specimens illustrating cerebro-spinal meningitis, and Miss Taylor's demonstration on the opposite reaction of the meningococci from London and Edinburgh cases of meningitis, and Mr. Wade's series of preparations of the appendix may be mentioned; and Dr. James Ritchie's demonstration of opsonins, in the College Laboratory. The meeting was pronounced a complete success, and was terminated by the members dining together in the evening.

LETTERS TO THE EDITOR.

"A SURREY DOCTOR" AND VACCINATION.

To the Editor of The Medical Press and Circular.

Sir,—Pray who is Mr. West, of Bradford-on-Avon, who, in your issue of February 12th, complacently asserts, without any hint as to how he arrived at his conclusion, that every medical man who has "ever" studied the subject is opposed to vaccination, adding, and that "they are legion"? This may be so, but it hardly admits of proof or disproof, so that Mr. West is trading on our gullibility when he asks us to accept his unsupported statement.

Again, who is Mr. West that he should declare bleeding, blistering, and sundry other therapeutical procedures to be "admittedly false remedies" in apparent ignorance of the unquestionable, and for the matter of that unquestioned, fact that they are in daily use under certain specified morbid conditions? It would be an impertinence on the part of a recognised medical authority to write in this strain, and for an obscure individual to do so is to expose himself to the imputation of ignorance if not rank stupidity.

Of course Mr. West may be a man of considerable scientific attainments, but even so that does not dispense him from the obligation of substantiating his assertions before making them the ground on which to declare our "ineptitude" to learn from experience

Admitting that vaccination is inseparable from danger, as stated by the "packed commission," so is trimming one's nails or picking one's teeth, but while the latter are cosmetic procedures vaccination has saved, and is saving, millions from a terrible disease, if the ordinary rules of evidence are to be accepted in proof—and if not what criterion is left except unsubstantiated and, on the face of them, foolish statements by Mr. West and others of his class.

It is a noteworthy fact that the Arabs, who are constitutionally opposed to treatment of any kind greedily welcome vaccination now that they have had a few object lessons on the subject, and this undeterred by Mr. West's platitudes.

I am, Sir, yours truly,

Alfred S. Gubb, M.D.

Algiers, February 18th, 1908.

CHRISTIAN SCIENCE.

To the Editor of The Medical Press and Circular.

Sir,—Mr. Sewill's last letter states his position in terms it is more possible to discuss.

Mr. Sewill now says that the spread of Christian Science "must lead to a vast increase in the amount of human pain and misery," and he bases this statement on the evidence at the inquest on the late Mr. Darlington. Now Mr. Darlington was a brilliant thinker and scholar who deliberately accepted a form of treatment which Mr. Sewill describes as "nonsensical"; he was a member of a great Christian sect who turned to what Mr. Sewill describes as a "blasphemous cult," and I venture to suggest that, both as a thinker and a Christian, his opinion was at least as valuable as that of Mr. Sewill. Finally, he was in the last stages of an incurable disease, a disease attended by considerable pain. It was shown at the inquest, not only that this pain had been practically destroyed, but that, in the words of one of the witnesses, himself the treasurer to a hospital, and consequently surely unbiassed, the patient "received spiritual, mental, and physical relief from suffering by treatment of the kindest, sweetest, and most beautiful kind." It would surely have been difficult to find a frailer foundation on which to base a charge of increasing human pain and misery.

No Christian Scientist has ever denied that the members of the medical profession are devoting their lives and energies unsparingly to the battle with disease and pain; on the contrary, they are repeatedly emphasising it. But that does not constitute an admission that they do not think there is a better way, a way based on the eternal fact of spiritual health instead of on the examination of physical disease.

In turning from Mr. Sewill's particular instance to his general principles you are confronted, as I have already said, by a colossal begging of the question. Because a certain number of physical experiments produce results approximating to some law of cause and effect, it does not in the least prove that this law is an expression of materialism and is inexplainable from an idealistic standpoint. Berkeley never maintained that if you put your finger ten thousand times into the fire you would not burn it ten thousand times, nevertheless he maintained there was "no substance of matter." Professor Ostwald has never said that if a man fell into the sea he would not be drowned, nevertheless he has said that "matter is only a thing imagined, which we have constructed for ourselves."

"If the hypothetical substance of mind is possessed of energy," Huxley wrote, "I, for my part, am unable to see how it is to be discriminated from the hypothetical substance of matter." Of course, it cannot be, and that is why Mrs. Eddy said, forty years ago, "Mortal mind and body combine as one." But she did not fall into the mistake of explaining matter as a mental phenomenon by recommending tar-water as a remedy, and so become, like Berkeley, "a mired logician." She pressed straight forward to the conclusion that mortal mind or energy was itself nothing but a negation of Divine principle, and that healing must be effected in consequence by the recognition of the fundamental fact of the allness of God.

"The phenomena of disease," writes Mr. Sewill, "are the outward show of solid concrete facts, the result of the action and reaction of matter and force." In other words, as I have already said, he adopts a definition of science limited to his own argument, and declares that anyone who applies the word science to anything beyond this is advocating "pernicious nonsense."

The day when it was possible to argue against Christian Science on such a basis as this is gone for ever. The one little Boston church has given place to the great building seating 5,000 people, and filled at every service. A thousand churches and societies, an innumerable number of meetings, are spreading like a network over the globe. Northward in Alaska and Norway, southward in the Transvaal and Australia, eastward along the Persian Gulf and the Chinese littoral, westward by the great lakes to the Pacific slope. Every week, from a thousand testimony meetings, there goes out the story of sin and disease of every description mastered and destroyed. The answer comes, as it came in Jesus' time, in a copious stream of denials, and when that will no longer do, in charges of hypnotism.

At the same time the evidence of Christian Science healing is much more definite than is commonly supposed. No one, I imagine, would maintain that cancer, epilepsy, and consumption could be destroyed by pretending; yet all these diseases are being destroyed by Christian Science every day. In the pamphlet entitled "Christian Science and Legislation," a copy of which I enclose, instances of the cure of these and many other types of disease are given, and, if anything was to be gained by it, such instances might have been increased indefinitely. The evidence in support of these cures is irrefutable, and has satisfied Judge Clifford Smith, a man trained by years of experience to sift and weigh evidence of every kind.

It is true that the Christian Scientist is to-day very much of a child. He cannot walk in furnaces or upon the water, but he is learning, as his Master taught him, with the finger of God to cast out the devil of sorrow, and sickness and sin. In hundreds of thousands of cases this is being done. And so long as it continues to be done there is no human power which can overthrow Christian Science, "lest haply it be found even to fight against God."

I am, Sir, yours truly,
Frederick Dixon.

SCIENCE, ITS OWN REWARD.

To the Editor of The Medical Press and Circular.

Sir,—In the House of Commons last week a member asked Mr. Haldane whether he was aware of the public service rendered by a Commission of the Royal Society in discovering the cause of Malta fever, from which many hundreds annually of our soldiers and sailors on that island till recently suffered; and whether, in view of the importance of this discovery, inasmuch as at the present moment the disease had been entirely stamped out, he would consider the desirability of giving the thanks of the Government to the Royal Society for this instance of the successful application of British scientific research?

In reply, Mr. Haldane said he was aware of the great service rendered by the Commission in question. Its recommendations had been followed by the practical disappearance of Malta fever from the garrison of the island. The Royal Society was well aware how genuine was the appreciation of the Government. The results illustrated the enormous importance of bringing science into our business of government. This is all very well so far as it goes, but it does not go very far. There is not the smallest suggestion of any intention to reward as they deserve the labours of the men of science—all medical men—who have performed this service to humanity. There is no suggestion of appropriating a suitable sum—say, at least, £100,000—to be divided among Col. David Bruce and his colleagues, through whose researches the results were brought about. Col. Bruce has won the F.R.S.; has gained wide scientific distinction; and with such honours he and all workers like him must at present be satisfied. The money value of his discoveries to the nation in preservation of the health of its soldiers alone represents a capital sum of not less than some millions; but no material return is offered for this. Material rewards are not gained by science; science, like virtue, is its own reward. Money rewards, and often wealth beyond the dreams of avarice, are reserved for the fraudulent concoctors of quack medicines, and for the army of impostors allowed and encouraged by the laws and by the newspaper Press to prey upon suffering humanity. By their individual labours in the investigation of disease, and by their work as the sole pioneers of national sanitation, the medical profession have performed an enormous service to the State, and, by improving the national health, have at the same time deprived themselves of great part of their income. Their only reward so far has been, so to say, the approval of their professional conscience—an asset not very tangible as a contribution to a livelihood, not very consoling to the crowd of practitioners who find it impossible under present conditions to live upon their scanty professional incomes.

I am, Sir, yours truly,
A Surrey Doctor.

February 20th, 1908.

ROYAL COMMISSION ON WHISKY.

To the Editor of The Medical Press and Circular.

Sir,—In the *Times* of to-day are published the names of the Royal Commission on Whisky and other potable spirits. The Chairman is Lord James of Hereford, and the seven other distinguished members include no less than four to whose names are appended the letters F.R.S. The terms of reference are, to inquire into and report whether, in the general interests of the consumer, or in the interest of the public health, it is desirable to place restrictions upon the preparation of Scotch or Irish whisky, or any spirit described as whisky, and to require declarations to be made as to the materials and processes of manufacture, or age of any such spirit, etc., etc. This Commission has been granted virtually at the request of the whisky trade.

The public are now spending nearly three millions annually on quack medicines. It is possible to demonstrate scientifically, and in most cases by simple chemical analysis, that at least 95 per cent. of these compounds are frauds. They rarely contain any potent drug, and when such is present it can be proved, as a rule, that it is either useless or harmful in the disease for which it is intended. It can be proved that the intrinsic value of quack medicines is always nominal, and that at the least the traffic in them is an organised system of pocket-picking and plunder. It can be proved that reliance upon worthless nostrums in cases where serious disease exists often allows pathological processes, which might have been cured in an early stage, to pass into an incurable phase. It can thus be proved that the quack medicine trade involves the infliction of a vast amount of unnecessary suffering and misery, and is truly murderous as well as fraudulent. All these things can be demonstrated beyond the range of controversy. Is it to be believed that if the medical profession were to exert themselves as much as the whisky trade have done, were to force their case to the front, they could fail in obtaining an authoritative inquiry not only into the nefarious traffic in quack medicines and apparatus, but into the whole question of quackery and practice by fraudulent pretenders. Does anyone who knows the facts doubt that the exposure which would be thereby effected would be followed by remedial legislation? Does anyone dispute that it is the pressing duty of the profession to throw their energies into this question, if not for their own sakes, for the sake of suffering humanity, who in this matter, unfortunately, can look with confidence for assistance in no other direction.

I am, Sir, yours truly,
REFORMER.

February 19th, 1908.

THE LONDON INTER-COLLEGIATE SCHOLARSHIPS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The London Inter-Collegiate Scholarships Board will hold a combined examination for twenty scholarships and exhibitions tenable at University College, King's College, and the East London College, on May 12th and following days. No candidates will be admitted to the examination unless they have passed the London University Matriculation, or an equivalent examination, and are under the age of 19 on October 1st, 1908. The total value of the scholarships offered exceeds £1,700. Full particulars and forms of entry may be obtained from the Secretary of the Board (Mr. Alfred E. G. Attoe), University College, Gower Street, London, W.C.

Thanking you in anticipation,

I am, Sir, yours truly,
ALFRED E. G. ATTOE,
Secretary to the Board.

February 18th, 1908.

OBITUARY.

R. S. W. WILSON, L.R.C.P., L.R.C.S.Ed.

MUCH distress was caused on February 18th throughout the district of Rossendale by the sudden death of Dr. Robert S. Walmsley Wilson, of Church Street, Newchurch. On the previous day he was about as usual, and appeared in the best of health. He retired at his usual hour, and in the morning, when a servant entered his bedroom, after knocking in vain, he was found dead in bed. Very few men were better known in the district than Dr. Wilson, who was 54 years of age. He was unmarried, and was a Liberal in politics. Educated medically at the University of Edinburgh, he qualified L.R.C.P. and L.R.C.S.Ed. in 1879.

RICHARD GORST, M.R.C.S., L.S.A.

WE regret to record the death of Dr. Richard Gorst, an event which severs a link which locally bound the present with the first generation of the past century. Born in Cheshire, in 1823, Dr. Gorst was able to say that he had lived under four monarchs, George IV. having been only recently proclaimed at the birth of the subject of this memoir. He was in his ninth year when William IV. and Queen Adelaide ascended the throne, and in his seventeenth at the marriage of Queen Victoria. He was educated at Edinburgh University, and qualified M.R.C.S. as long ago as 1848, taking the L.S.A. ten years later. Dr. Gorst was one of the best-known practitioners in South-West Lancashire, residing first at Prescot and then for many years at Huyton. Up to within two or three years of his death the deceased gentleman, although in his eighty-fifth year, enjoyed robust health, for which his love of fishing, shooting, and other outdoor sports, associated with regular habits, largely accounted.

ROBERT SYDENHAM FANCOURT BARNES.

WE regret to announce that Dr. R. S. Fancourt Barnes, Consulting Physician to the Royal Maternity Charity, died on Thursday at Sunningdale, West Worthing, at the age of 59. He was son of the late Dr. Robert Barnes, Consulting Obstetric Physician to St. George's Hospital, and studied for his profession at Aberdeen and St. Thomas's Hospital, taking the M.B. and C.M. degree at Aberdeen in 1875, being elected a member of the Royal College of Physicians, London, in 1877, and proceeding to the M.D. degree in 1878. Dr. Fancourt Barnes had devoted much study to the subject of midwifery, and besides being Consulting Physician to the Royal Maternity Charity, had been Consulting Physician to the British Lying-in Hospital, Obstetric Physician to the Great Northern Central Hospital, Physician to the General Lying-in Hospital, Senior Physician to the Chelsea Hospital for Women, etc. He was a Fellow of the Royal Society of Edinburgh and of the British Gynæcological Society, and of various learned societies of the Continent and America, and he had been editor of the *British Gynæcological Journal* and on the staff of the *British Medical Journal*, and was the author of several medical works.

JOHN HENRY REGINALD PIGEON, L.S.A.

WE regret to record the death of Dr. J. H. R. Pigeon, of Stapleton Road, Bristol. On Monday week he was attending to his professional duties, when he fell a victim to the prevailing epidemic of influenza. Pneumonia afterwards set in, and about 10 p.m. on the Wednesday he was conveyed by the ambulance to the Bristol Royal Infirmary, at which institution he had received his training. When admitted, he was in a delirious state, and passed away about 2 o'clock the next morning. At one time the deceased acted as assistant to Dr. W. G. Grace, and was attached to the same sport as the veteran cricketer, in addition to being a keen fisherman. Dr. Pigeon went on some voyages as ship's surgeon before settling down to practice.

DR. CONNOLLY NORMAN.

WITH deep regret we announce the death of Dr. Conolly Norman, Resident Medical Superintendent, Richmond Lunatic Asylum, Dublin, which occurred with painful suddenness on Sunday last. About 4 o'clock in the afternoon Dr. Norman left his residence, St. Dympna's, North Circular Road, Dublin, for a short walk, but after going a few hundred yards he became ill, and collapsed on the pavement. He was quickly removed to his home, but he died almost immediately. He had been unwell for some months past, the result of influenza followed by bronchitis, and his heart was also affected. As the sad news of his death only reaches us as we are going to press, we are only able to publish this brief notice, but in our next issue we hope to refer to his long career as a distinguished alienist.

LABORATORY NOTES.

FORMAMINT.

WE have received samples of Formamint from Messrs. Wulfing and Co., who introduced the preparation to the profession. Formamint is a chemical combination of formic aldehyde and milk sugar, having the formula $5\ \mathrm{C\ H\ O\ H}\ C_{12}\ H_{22}\ O_{11}$. Its combination has deprived the formic-aldehyde of its irritative effect on the mucous membrane of the mouth and throat. Experiments with formamint show that it has no internal effect, such as that due to the administration of pure formic-aldehyde, such as formalin. Its composition is .01 gram formic aldehyde in every gram tablet of formamint. The tablets are allowed to dissolve in the mouth. The action of the saliva sets free the formic aldehyde in a nascent condition; this has an immediate bactericidal action, with the result that Formamint is indicated in all cases demanding asepsis of the oro-pharyngeal regions, the saliva containing Formamint being carried into every crevice of the mucous membrane lining the mouth and throat. Among the conditions in which its use has been favourably reported on are pharyngitis, quinsy, follicular tonsillitis, mumps, otitis media, pyorrhœa alveolaris, scarlet fever, diphtheria, measles, and thrush; also in streptococcal infections, erysipelas, and erythema nodosum. We venture to think that Formamint is already widely known in the profession.

THE following Bill was presented and read a first time in the House of Commons on February 19th:—Sir J. Tuke (Edinburgh and St. Andrews Universities).—Bill to prohibit joint stock companies from acting as physicians, surgeons, or medical practitioners.

REVIEWS OF BOOKS.

MANUAL OF BACTERIOLOGY. (*a*)

WHEN the first edition of this manual appeared ten years ago, it at once sprang into popularity as a thoroughly reliable practical treatise on bacteriology, and with each successive issue it has strengthened the position it then took. The fourth edition now before us has been thoroughly revised, and is as fully representative of the contemporary status of bacteriology as its predecessors have been. During the four years which have elapsed since the third edition appeared, many advances of first-rate importance have been made, and, in consequence much new matter has been incorporated, without, however, materially increasing the size of the volume. We have only space to refer to a few of the alterations, but it ought to be stated generally that the authors, in re-writing their book, have adhered to their former plan of giving special prominence to the clinical aspects of their subject. The introductory chapters on methods have been thoroughly brought up to date, and now include, among other novelties, descriptions of Gordon's fermentation tests, the newer eosin-methylene blue stains, Graham Brown's chamber for anærobic hanging drops, and descriptions of the various forms of pipette, etc., which we owe to the ingenuity of Sir A. E. Wright and his collaborators. The account of the meningococcus rheumaticus is ample, and Beattie's work in this connection is referred to. The section on Weichselbaum's meningo-coccus has been considerably amplified, and mention is made of Flexner's researches, as well as Houston's work on its opsonic and agglutinative properties. Under tuberculosis the relations of bovine and human tuberculosis are discussed, and the findings of the Royal Commission, issued only a few months before this volume appeared, are alluded to. Recent discoveries in connection with the transmission of Malta fever and of plague are discussed, and there is a good description of present opinion on paratyphoid fever. Some of the chief additions concern the protozoal diseases. The spirochæte of syphilis is described, but, pending more exact knowledge of its biological condition, the writers have retained the disease, as also relapsing fever, among those due to bacteria. Protozoal diseases proper are fully dealt with in the appendix. Schaudinn's proof of the non-identity of the amœba coli and the amœba dysenteriæ is given, and the study of the life cycle of the malaria parasite has been much enlarged. There is a full description of the pathogenic trypanosomes, mention being made of Schaudinn's work on the hatteridium; an account of the parasite of kala-azar, and of the piroplasmores is also included. There is a very valuable chapter on immunity, which is both a most lucid and thoroughly up-to-date exposition of this difficult subject. This brief sketch of a few of the changes which have been made is enough to show that to a large extent the volume has been re-written, and we can confidently recommend it as a most excellent and readable treatise, admirably adapted to the study of all who wish to keep abreast of modern bacteriological research.

KEEN'S SURGERY. (*b*)

THE second volume of this excellent work deals with the various lesions of the bones, joints, muscles, lymphatics, skin, and nervous system. There are 13 chapters in all. The first four deal with diseases of and injuries to the bones and joints, and are contributed by Nichols, Eisendrath and Lovett. Then follows a chapter on the surgery of the muscles, tendons and bursæ by J. F. Binnie. The three succeeding chapters deal successively with orthopædic surgery, by R. W. Lovett; the surgery of the lymphatic system, by F. H. Gerrish; and the surgery of the skin, by J. A. Fordyce. The last four chapters deal with the surgical disorders and the surgery of the nervous system, and include a chapter on "Surgery Among the Insane and the Surgery of Insanity." These chapters are written by W. G. Spiller, G. Woolsey, F. X. Dercum and J. C. Da Costa.

The chapters on the surgery of the bones and joints take up quite half the book, and are very valuable contributions to surgical literature. The chapter on fractures is especially excellent, and is profusely illustrated. We are glad to notice that amongst the descriptions of the different fractures a full description is given of the fracture of the thumb metacarpal, described by the late Professor Bennett, of Dublin.

The surgery of the nervous system is also very full, and particularly good illustrations are given of the various operations on the nerves of the face. We hope that the importance attached to the description of hæmatoma auris amongst lunatics is not indicative of the frequency of that condition in American asylums. It has four pages devoted to it, and so lengthy a description in a work on surgery coming just after a very unpleasant description of the methods adopted in certain American asylums (which description lately appeared in the columns of the general Press), makes one rather suspicious. There are still three more volumes of this important work to appear, and if they are up to the same standard of excellence as their predecessors the book will be very hard to beat.

NEURASTHENIA. (*a*)

NEURASTHENIA is one of the diseases of modern life. The fact that Dr. Savill's admirable monograph has passed through three editions since its first appearance in 1899, is significant. Both the medical profession and the nervous public are concerned in the study and management of this prevalent and distressing malady. Dr. Savill's work will doubtless be read by representatives of both these classes. It is a comprehensive, suggestive and reliable treatise which, while dealing with the subject in a thoroughly scientific manner, is also practical and helpful. The form of the clinical lecture is followed throughout. The lectures dealing with diagnosis, pathology, and treatment have undergone considerable amplification for the present edition, and a new lecture has been added on etiology and prognosis. Dr. Savill believes that in all cases of neurasthenia there exists some degree of weakness of the nervous system, inherent or acquired, which renders the nervous system vulnerable to a number of disturbing influences, such as overwork and mental strain. He holds, however, that the gastro-intestinal symptoms, often regarded as a part of the disease, are really indicative of an antecedent causal gastro-intestinal derangement. In an analysis of the author's cases about 80 per cent. were found to be the subjects of some kind of auto-intoxication. A specially commendable feature of the work is the very serviceable and up-to-date bibliography prepared by the author's wife, Dr. Agnes F. Savill. We commend the volume to all physicians and medical advisers of latter-day valetudinarians.

McISAACS' NURSING TECHNIQUE. (*b*)
